Atmospheric pressure will probably have at least as much effect in preventing water from rising as in forcing it down. The effect which the pressure of water descending has in forcing water to return again towards the surface must cease as soon as the level of the stratum is reached which bears it away to a lower level. That level was necessarily reached by the water Mr. Bennett got in his shaft wells, if he was successful in obtaining it at all.

Rightly or wrongly, I infer from Mr. Bennett's use of the term shaft well in his letter that he thinks a pipe or tube well would have the effect of giving artesian water in places where it has not risen in shaft wells. This would only be possible on the supposition that the pipe reaches a lower water totally unconnected with that which is in the shaft. And if a case were to occur in which this was done, and the lower water found to be artesian, how about Mr. Bennett's pressure? If his theory is correct, the pressure should surely apply in the first instance to the upper water—or is that only in course of being pressed down to the large cavern or reservoir? In that case, however, the water cannot rise from the reservoir to the surface, because it is not full; if it were full, no more water could get down, therefore the top water should rise as well as that which is underneath.

If it is correct that the well-supplies are obtained from surplus rain water, and that the power which forces it to rise to any given level is derived from the water itself, proceeding first from the surface and forcing itself downwards and upwards again as the various strata fill, then there must be streams or water-bearing strata at that given level which carry the surplus water away somewhere. Surplus, that is, after the strata become fully charged; and this seems to be proved by the fact that at places along the coast, notably and to my own knowledge at Port M'Donnel, fresh water rises through the sea, and can be both seen and tasted, while in the limestone country inland there are streams flowing towards the sea, which can be seen in caves and through holes in the ground under large districts in the south-east of South Australia.

I have said that if it is correct that the well supplies are obtained from the surface directly—that is, if the power which raises the water to a given height is merely that of water rising again towards the level of its source—there must be streams of water-bearing strata carrying the water away, and these must have a very peculiar capacity, because it is a fact that, no matter how long the succession of wet seasons, and no matter how wet they be, the water level in deep wells does not rise, while equally in dry seasons it does not fall, neither does the supply diminish.

If such streams are the outlet for the surplus rain water, there can be no artesian water derived from that source with these channels of outlet, so long as the outlet is sufficient. Not only so. Artesian wells can never be got from any water, no matter how deep, which has any connexion with that which has such an outlet, unless it derives its power of rising from a pressure outside of mere gravitation.

If the outlet were only insufficient, any artesian water from such a source could only be intermittent.

If these or such as these streams be not the outlet, all underground water should be artesian. Because unless there is some other means of disposing of the enormous supply of "constantly descending water," the water bearing strata must surely fill by degrees higher and higher upwards from the "bed rock," and in time the water in the well must rise to the surface.

I know of no one who can tell by any given indication where to sink a well, tube, or shaft, to ensure probable success. All the work is done in the dark, and success varies in different districts, and in different parts of a district, to such an extent that I am inclined to think no one ever will be able to tell. If any one, by theory or otherwise, could guide water-seekers in this matter, he would deserve all the credit Mr. Bennett asks for.

The whole question is a very interesting one, and must be taken up by scientific men, who know more about the subject and the laws by which it is governed than most of us practical workers, before anything will be made of it by writing. We are content to go blundering on, sinking here and boring there, satisfied if water is got at all, without much caring where it comes from or how it comes.

There is, however, a large mass of information, and an accumulation of fact, possessed by well-sinkers, station-owners, and managers, which would be of great use to a scientific man, if by any means he could collect the useful portion.

My own opinion is, that artesian water will not be got generally in Australia, except, perhaps, at great depths, although water which will rise to a given level, will almost invariably be got at reasonable depths, say 500ft. or less, and of varying quality. As a rule, the greater the depth the better the quality. Where artesian water is got, my opinion is that it will always be fresh, or nearly so, and that it will be found to derive its power of rising, not in that it enters the ground and works along between two impervious strata till they crop up to the surface, when it should be got between them, but in that it comes from a very low level, and is forced from there probably by gas or heat generating steam. And if that were allowed to be a possible theory, I should also be of opinion that much of the water in the deep wells which rises so far, and no farther, also derives its power from some such source—from one, at all events, less variable than surface supply. I refer solely to Central Australia, not to the country near the coast ranges.

Apologising for the length to which I have drawn out this letter, my only excuse for which is the interest so large a portion of your readers in this and other dry districts take in the question, I would, in conclusion, ask you or any of your readers to draw attention to any book or pamphlet which may have been written on the subject of water-supply referring to Australia. I know of none.—Yours, &c.,

DAVID BROWN.

Kallara, Darling River, March 22.

ARTESIAN WELL BORING.

(To the Editor of the Australasian.)

SIR,—In your issue of April 2, under the heading "Station Improvements," a letter from "Paroo" appears, in which reference is made to a misunderstanding that has arisen with regard to the use of Messrs. Wright and Edwards's water auger at Mount Wilson well.

As my name appears in that letter, and "Paroo" requests me to state the manner in which the boring was carried out, I shall comply with his request, wishing at the same time that he had named others in the district, who have had far longer experience in the use of this machine, consequently better qualified to point out its advantages or deficiencies. I shall, therefore, confine myself solely to the description of the boring of Mount Wilson well, which is the question "Paroo" wishes to "be set at rest."

When this shaft was first started, it was intended that it should be sunk until water would be struck, but after going down 300ft. through a sort of blue slaty substance, containing an innumerable quantity of shells of marine formation, the work was suspended, and it was thought advisable to try Messrs. Wright and Edwards's water auger, which would be a cheaper method of solving that rather doubtful problem, "Does fresh water lie underneath this blue slate, which seems to be so widely spread over the back Darling country?"

The machine arrived, also a person with it (Mr. J. A. Niemann), who had some experience in the working of the machine. His opinion was, when he examined the shaft, that what he called "bottom" had been struck, and that it was useless to go further in search of water. However, it was determined that the boring should go o[illegible]e bottom of the shaft to find out to what depth the blue slate [illegible] also to find out what lay underneath, even if water was not struck.

After two unsuccessful attempts, the tubes in each case either breaking or jamming at something over 100ft., water was at length obtained at a depth of 184ft., or 484ft. in all from the surface.

Now, as to the method of the "boring," which seems to be the point of difference between "Paroo" and Messrs. Wright and Edwards. The tubes, rods, and auger alone, with appendages, were used, the machine itself never having been taken out of the box in which it was packed until the present day. The tubes, with steel cutter attached, are turned round by means of a lever, which has steel teeth that can be screwed up to gripe the iron tube. Another lever of a similar sort is used for turning the rods, at the end of which is attached the auger. When the rods are turned round the auger bores its way down, and becomes filled with the substance through which it passes. The rods are then drawn up the shaft by means of a "whim" or other appliance, and remain suspended in the shaft whilst the auger, at their opposite extremity, is being cleaned; meantime the tubes h[illegible] turning round, which, with the cutter attached, sink down an[illegible]e space of the material that has just been taken out [illegible] By this method it is easily seen that a great amount of l[illegible] saved, as it is unnecessary to screw and unscrew each joint [illegible] pipe every time the auger is raised to be cleaned. When rock is struck, the tubes are drawn by the same method as the rods and an ordinary steel jumper (a little larger than the tubes) substituted for the auger. The jumper i[illegible]d in the ordinary way, and the rods are of sufficient weight of them[illegible] to force the jumper through the rock. We are working at a w[illegible] present on this principle, and have reached 470ft., 8ft. of which

been through solid rock, in strata varying from a few inches to 2ft. or 3ft. in thickness. I forgot to mention that at Mount Wilson well no salt water was struck, but at a depth of 140ft. a small supply of fresh water was obtained.

I do not think that Messrs. Wright and Edwards's machine would bore to such a depth as the wells I have described. In this back country strong supplies of very salt water near the surface are often struck—so strong that in many cases the shafts have to be abandoned.

Now this machine would be suitable for finding out spots where this salt water does not exist; and where such a spot is found, I would recommend sinking 200ft. or so in the usual method, and then using the rods in the manner above described, so that over 400ft. could be reached without any unscrewing—which, to my mind, is the greatest drawback to the machine.

Hoping, Sir, that you will pardon my rather long explanation, and desiring to see others giving their opinions on these important matters, I am, &c.,

ROBERT A. CHESNEY.

Dunlop, April 9.

SCIENTIFIC CRITICISM.

(To the Editor of the Ceylon Times.)

SIR,—It has occurred to me that the results of what has been termed highly scientific cultivation of coffee in Ceylon has been somewhat on a par with the effect of Liebig's essence of beef on the human system. This essence undoubtedly contains all the active and nutritive principles essential to support the life of man, and yet we know as a fact that man or animals cannot be supported upon it alone; combined with other bulky materials it answers the purpose well enough, not otherwise.

I suppose you remember the reply of the old-fashioned planter to the statement of a neighbour that some clever scientist had invented a coffee manure of great power, the value of which was in its great portability, for that an ounce or two would suffice for a tree. The old planter remarked, "yes, he will carry his manure in one waistcoat pocket and take away the crop in the other."

It appears to me as though a good many amongst us had been living in a fool's paradise as regards cultivation. I for one shall never have any faith in agricultural scientist until they can explain why Haputalle has continued to give good crops for a quarter of a century without manure, when young coffee in other districts refuses to give good crops even with the aid of manure. Why did not Mr. Morris pay a visit to the Ouvah side of the country when he was requested to do so, in reference to leaf-disease, though I am ready to confess that there are other districts in which the attacks of the coffee pest have been successfully resisted without science, and as I believe without expensive manures.

Whilst on this subject allow me to ask if the scientists can offer any explanation of the terrible mortality amongst cinchona seedlings, plants and trees. They die off at all ages and no body has yet discovered why this happens.

AGRICULTURAL COLLEGE.

(To the Editor, Madras Times.)

SIR,—It is gratifying to learn that after a dead silence for five years, the Government have sanctioned the entertainment of three agricultural instructors, two for Tamil, and one for Telugu districts, on a monthly salary of Rs. 60, to be increased to Rs. 80 by biennial increment of Rs. 4. The Principal of the College is now prepared to receive applications from the candidates who have a first class certificate of the College, and who are thoroughly acquainted with the language of the district in which the candidate seeks employment. I hear from a reliable source that one of these is to be given to one of the late students. Out of the remaining two, reserved for the present students of the College, one will be secured by the Brahmin scholarship student, and the other by a Moodeliar, as the former stands high in rank among the applicants who took Tamil as their optional language in the University Entrance Examination, and the latter is the only student among those who took Telugu as the optional language. As the nature of the post requires a thorough knowledge of the vernacular of the district, for obvious reasons, there is nothing to be said against the intended selection, which is an impartial and sound one. But what I wish to ask is, of what earthly use is the second class certificates of the College, if only first class certificates are valued? Hitherto we satisfied ourselves that the second class certificated students of the first batch would be provided with employments prior to the first class certificated students of the present classes. Alas! we are really disappointed. The Agricultural Department is no better than the other branches of the Revenue Department, in doing justice to its subordinate. It would fully resemble the Collector's Department in every respect should the three new appointments be conferred on three Brahmins instead of two Brahmins and a Sudra, as is likely to be the case.

EX-STUDENT.

CINCHONA AND COFFEE STATISTICS.

(To the Editor, Ceylon Times.)

SIR,—The advice rendered by the Chairman of the Planters' Association to your contemporary in regard to the preparation of statistical returns of cinchona and coffee, is no doubt perfectly correct in principle, but it is difficult to understand the value of such returns when they are compiled. Tabulated returns of the acreage of coffee are always looked upon as misleading, at any rate in most of the older districts, and indeed they must be misleading until we are able to deduct from the areas given the extent of coffee which has long ceased to be an element in the matter of crop. Not only are these figures misleading, but they are actually prejudicial to our good name as coffee producers, because these over-statements of acreage certainly reduce the apparent average of yield per acre.

With regard to attempting to tabulate cinchona areas without utterly misleading the public as to our future corps of bark, I maintain that it is impossible. In the case of coffee, readers of these returns are misled by what has died out and what has ceased to yield, with regard to cinchona they will be equally misled by figures representing what are never likely to produce crop. What practical end can be attained by counting all the chinchona plants in the island in 1881, when a half the number may not live to see the next year, or at any rate may not live to see their fourth year, I regard all this attempt at arriving at correct data as simply so much trouble thrown away.

I am equally at a loss to understand what the Chairman of the Association intends to convey in telling us that whereas a good many years ago there was a difference in the value of plantation, coffee equal to 20 shillings the cwt, a greater part of which difference has now ceased to exist, and yet immediately afterwards tells us that the quality of Ceylon coffee has not deteriorated. Now if this difference in value has disappeared, it does not require much argument to shew either that some of our coffees have declined in value, or that others have very much increased in value. How otherwise is it possible to account for this equalisation which we are told exists at the present time. No doubt cultivation has been improved of late years and so likewise the preparation of our crops in Colombo. I wish I could say that this was the case in all instances. It is to be feared however that if the natural quality of our bean has not degenerated in growth, some influences in Colombo godowns are at work unfavourable to the market value of the article, because I have been told by friends who have made the experiment, that portions of their corps shipped by some firms have realised at home far higher prices than other portions shipped by different firms. How is this to be explained is the question. If the able and experienced Chairman of the Association could throw any light upon this matter, it would be of more practical value than attempts at framing planting returns which are bound to be misleading.

PROPRIETOR.

May 23rd.

AGRICULTURE IN INDIA.

(To the Editor of the Madras Mail.)

SIR.—Agriculture in this country, as an art and a science, has been neglected. No improvement or advancement has yet been affected. There can be no doubt that the wealth of India lies buried in her soil, which, by judicious cultivation, can be raised therefrom. From time immemorial, not only has the soil been cultivated in the rudest possible manner, but the first principle of agriculture, *i.e.*, to give back what is taken from it, has been disregarded. In no land, more than in India, has this law of restoration been ignored, for her soil, from being once fertile, has become impoverished, and the once renowned garden of the East has become sterile. The fact that most of our fields are deficient in the food necessary for the proper development of grain, and that this has been caused by the processes of exhaustion continually going on, cannot be disputed in the face of statistics showing the relative outturn of the past and the present. To make it clear in the seventeenth century the average produce of rice, of wheat, and of lint cotton, amounted to 1,340lbs., 1,155lbs., and 228lbs. per acre respectively. But in the present century, the produce has been, of rice 800lbs., of wheat 650, of lint cotton 53lbs. per acre. Looking at these figures, are we not surprised to see the

condition to which India has been reduced by the neglect of men of intellect, who are, for the most part, mirasdars (landholders). These men forget the fact that kings have risen to the throne from the plough, and have left the cares of the State amidst the blessings which an agricultural life affords. 'The Roman Consul Cincinnatus, the saviour of Rome, took to the plough, resigning the cares of the State, and instances can be multiplied.

It is not only the time-honored custom and the superstition in India that hinder any progress towards improvement in agriculture, but, to a certain extent, the present system of education. The blessings which education has conferred on the public are manifold, but the disadvantage is that young men, studying in the colleges established by Government, have for their goal, only Government employ, and cast a disdainful look on agricultural life. Many, unlike those in America and Germany, in pursuit of their livelihood, are called to the bar, encourage litigation, and extort from the ignorant ryot his small earnings, won by hard and honest labour, and hoarded by an economy that involves semi-starvation. Others wander up and down the street, haunt the houses and offices of the head officers of the district in quest of employment, and thus waste their time in the wild hope of obtaining high positions in the public service. Day by day such a state of things is increasing, and professional studies are uncared for. I do not mean to say that no professional study is encouraged. Civil Engineering and Medical Colleges have been established for this purpose. The Civil Engineering College turns out a body of trained men, and the Medical College sends out each year young men well versed in the science and practice of medicine, who are useful to the country. Noble as these professions are, there is another which contributes greatly to the well being both of nations and of individuals, but which, it is to be regretted, has received but indifferent attention at the hands of the rulers of this purely agricultural country. Education in agriculture, which is the backbone of the prosperity of a country, has been neglected to a sad extent, and the result is evident in the recurrence of famines, aggravated by the pressure of a fastly increasing population. The Court of Directors of the Honorable East India Company, in their despatch of the 19th July 1854, on the education of the people, observed, "No single advantage that could be afforded to the vast rural population of India would equal the introduction of an improved system of agriculture." Since that time no step has been taken towards this end. The indispensible necessity for an advanced agriculture to the comfort and wealth, and to the very existence of a nation, renders it an object peculiarly worthy of the attention of those who desire that India should regain the prestige which she once possessed. It is, therefore, incumbent on the rulers of the country to give their earliest attention to the dissemination, among all classes, of a sound agricultural education.

A FARMER.

THE AGRICULTURAL DEPARTMENT.

(To the Editor, Pioneer.)

SIR,—What is the first duty of the department at the head of which Mr. Buck reigns? Is it to introduce "improved" ploughs, copied from American and English models to work in the tiny plots which make up the small and scattered Indian holdings? Is it to stir up the fleeting effervescene of native enthusiasm in an agricultural show? Is it to write reports on the grain trade of the N.-W. Provinces? Or is it after all to improve the soil, so that it may produce to perfection the superior food grains and staples of the country? A few thousand "improved" ploughs may be sold every year without in any way increasing the yield per acre. An Indian Agricultural Show comes and goes with the only result, that a decided feeling of relief comes over all concerned when the improved threshing machines, pumping machinery, steam ploughs, and patent manures have left the district. And a report on the grain trade of the province is met with the reply from those interested in the matter. "We knew all that before, but please show us how to get cheaper and better wheat. So it resolves itself into this that the permanent improvement of the physical condition of the soil is the subject which deserves the greatest attention from the Agricultural Department, although as a matter of fact it is the one which is most neglected. Nevertheless it is the one thing in Indian agriculture over which the Government has almost perfect control. The condition of millions of acres of the land in this country can be changed from bad to good at the will of the Government; and yet without doubt it is shown that this condition is slowly progressing from bad to to worse in extensive tracts of country in the N.-W. Provinces. This fact is well known to all who have studied the subject, and in the following words, it is put before the public by Mr. Hume more strongly and truly than ever I could put it:—" Yet again, from another and distinct source, ruin and desolation, more palpable and speedy in its course, though more limited in its operation, await vast tracts in Northern India, unless the voice of reason can gain a hearing and science be allowed to guide agriculture. In Oudh, the Punjab, and the N.-W. Provinces the soils mostly contain an appreciable admixture of saline particles. With the construction of high level canals, the subsoil water level is raised, the surface flooded, the earth yields up its soluble salts to the water, which again restores them (back on the surface) as it passes away in vapour. At first the result may be good and marvellous are the crops that have been raised in the Doab on the first introduction of canal irrigation, owing to the first slender doses of potash and chloride of sodium. But Nature works on blindly and unceasingly. The water below searches out one by one each soluble particle in excess of the particular soil's capacity of retention, and as it slowly creeps up by capillary attraction, leaves these ever behind it on the surface. Time passes on, some crops begin to be unprofitable; in the hottest time of the year, a glimmer, as though of a hoar-frost overspreads the land. The land grows worse and worse, but ever night and day Nature works slowly on and the time comes when, abandoned by the cultivator, the land glitters white and waste as though thickly strewn with crips new fallen snow; never, alas! to melt away, except under the rays of science. Along the little old Western Jumna Canal thousands of fields are to be seen thus sterilized. Along the course of the mighty Ganges Canal—a work, as it were, but of yesterday—the dreary wintry-looking rime is already in many places creeping over the soil. Come it quickly or come it slowly, the ultimate result here also is certain, and unless a radical change is effected in existing arrangements, we know as definitely as we know that the sun will rise to-morrow, that the time must come when some of the richest arable tracts in Northern India will have become howling saline wastes." I make no excuse for quoting so extensively from Mr. Hume's excellent little pamphlet on Agricultural Reform in India. The above-mentioned sentences should be printed in letters of gold and hung up in every Irrigation Officer's office. This little pamphlet attracted considerable notice when it first appeared, and probably these lines which I have just quoted were read by nearly every European interested in the agriculture of Northern India; but have any steps been take to check the evil which is so graphically described by the late Secretary to the Government of India in the Department of Agriculture? It appears not as we actually find that summer irrigation with canal water is increasing in the N.-W. Provinces: indigo factories are springing up on all sides; and the demand for water is only limited by the supply. A well-known native gentleman from Cawnpore (who is himself a large indigo planter and seed merchant), speaking to me the other day of this increase of indigo cultivation under the influence of canal irrigation, mentioned that the zemindars of a certain district were asked if they would like the canal system extended to their estates. They objected, saying "God forbid! we do not want our wheat and barley fields ruined for the sake of indigo." A horrible satire this on the efforts that are being made by the Government to protect the country from the ravages of famine, and yet it is the pith of the argument against canal irrigation during the summer months in Northern India. These finely divided alluvial soils may be likened to a huge sponge of exquisite texture. When high level canals are run through them, the subsoil is water logged and the spring level is raised; then irrigation by natural flow, particularly in the hot weather, adds to the evil; and capillary action goes on unceasingly to an alarming extent so as to increase the saline efflorescence to such an extent that the land eventually becomes barren, more particularly in those tracts where the rain-fall is partial and light. It is a fact that no saline efflorescence is found on land where the rivers or canals overflow their banks annually and leave a plentiful deposit of silt; the surface soil is renewed and covered, and capillary action to a great extent is checked; and this probably will account for the soil in Egypt being so fertile; besides the temperature there is low. But the porous alluvial tracts of Northern India, which are exposed to the action of a burning sun from one year's end to the other, are bound to suffer from the evils arising from excessive capillary attraction, particularly when the subsoil is fed with water from a network of high-level canals. Too little attention has been bestowed upon the physical property of soils in India, and yet it is the most important question of the day as it affects the condition of millions of acres of land in our most thickly populated districts. The only measure to check the evil is a heroic one; and that is to drain the canals and their distributaries of water during the hot weather, from February to October; and during the *rabi* season to allow canal irrigation by lift only. Will the Agricultural Department have the courage to propose such a course? I am afraid not, as unfortunately the independent action of the authorities in this country is trammelled by the ignorant interference and criticism of people at home, who think the country is on the road to ruin if they do not see a profitable balance sheet; and as indigo and sugarcane are the two crops which make the canals of Northern India pay, the very idea of prohibiting the summer irrigation of these crops from

the canals is enough to take the breath away from an ordinary N.-W. Province official. But until this is done, the outside public will scarcely consider that the Agricultural Department has done its duty. There is an increasing knowledge springing up among both Europeans and educated natives in this country regarding the principles which guide true agricultural practices; and unless Mr. Buck's department wants the finger of scorn pointed at it for ever, it had better bestir itself to check the evil now being perpetuated by summer irrigation from canals.

CALCUTTA, JULY 1, 1881.

IRRIGATION.

MR. BUCKLEY'S work on irrigation in India supplies a want which has long been felt by those interested in that most important and difficult subject. The author tells us that when employed as an Executive Engineer in Bengal, he often found the greatest difficulty in obtaining information concerning any irrigation works other than those to which his own services were given, while he often heard the wildest statements made as to the profit made by Government on canals in distant provinces. This experience was by no means peculiar to Mr. Buckley, and the general ignorance was excused by the fact that there existed no book which gave any comprehensive account of our canals. The volume before us deprives all of this justification for want of knowledge. In the clear, easy style which sometimes characterizes the writings of distinguished or rising Engineers, it gives a detailed description of the nature of each irrigation work, both from a professional and a financial point of view. A map at the beginning of the volume and elaborate statistical tables at the end illustrate and condense the information which it contains. The Indian system of furlough gives departmental officers the leisure necessary for the preparation of such useful works, and in this instance all must acknowledge that it has been well used.

Among the subjects connected with India which have formed the subject of Parliamentary controversy few challenge attention in a manner so marked as that of irrigation. The works already executed have this pre-eminence, that of their kind they are undoubtedly the largest which the world has ever seen. The ancient aqueducts on the Tigris and Euphrates, the canals which at present intersect those regions and the more fruitful parts of Central Asia, as Bokhara and Khiva, the watercourses constructed on the slopes of the Alps, the Pyrenees, and the hills of Cashmere, the works of the Hindu rajahs in ancient Hindustan, are all on a smaller scale, while the dykes of the Netherlands have been made with a different object. There are at present in India 12,750 miles of irrigation canals, besides distributaries watering 6,310,000 acres, and made at a cost of twenty millions and a quarter sterling. These figures indicate works of a magnitude never undertaken by any State for a purpose absolutely unconnected with defence or aggression.

It may be supposed that canals, however numerous, can have little professional interest for the engineer, as being monotonous and tame. There is certainly nothing striking or picturesque in a series of big ditches intercepted by locks. But the headworks, as they are called, of each irrigation system, are magnificent monuments of engineering skill. Before water can be distributed to fertilise the plains, it must be caught and stored where rivers debouch from the hills, and this is a work of no ordinary difficulty. The wizard Michael Scott is said to have "bridled the Tweed with a curb of stone," and this is exactly what our engineers have to do for rivers compared with which the Tweed is but a rivulet. The Ganges and Jumna canals have at their commencement to be carried at right angles across the drainage of the country, sometimes above, sometimes below the beds of mountain torrents, through or round the spurs of mountains. At Cuttack a clear and beautiful lake has been formed in front of the city and at the foot of the surrounding mountains by three large rivers whose united length is nearly three thousand miles. This is certainly the most picturesque sheet of water in Bengal. Nearest to it in beauty is the lake formed at Dehree by the longest weir ever built in one unbroken line of masonry, the Soane having been fairly "bridled," at the foot of the Kymore hills. That these works are by no means simple in their nature is proved by the fact, witnessed by abandoned locks and altered lines, that grave mistakes have from time to time been committed in their construction. Thus the Ganges Canal was constructed by Sir Proby Cautely on a system entirely wrong, which had to be remodeled at great expense.

Mr. Buckley disputes the assertion of the House of Commons Committee of 1879 on Indian Public Works, that "the financial results of works of irrigation are the best test of their utility." It is true that the canals act as famine preventatives, and this is a benefit independent of the returns in money. Moreover the State may not take from the cultivator the whole of the additional produce which irrigation causes. Where such is the case, a canal not remunerative to the State may be of use to the people. It is, however, a fact that financial success is the only test which the public can apply, and it is an excellent one. The cost of constructing canals has been defrayed from borrowed money, the interest of which is discharged out of the products of taxation. As long as any part of the revenue of the country is derived from a source so tainted as that of the license-tax or the salt duty, it must be said that the loss caused by a canal which does not pay its way has to be covered by unpopular or objectionable imposts. The exchequer has not the means of securing for fragments of the population here and there, who chance to live near the best rivers, extraordinary protection or profit at the expense of their less fortunate fellow-subjects. Moreover, now that the total outlay on public works for each year is limited, canals come into direct competitions with railways, as whatever is given to the one is taken from the other. Now railways, which run in all weather, and bring grain to every district, are more powerful for the relief of famine than canals, which dry up when the rainfall is very scanty, and they are therefore wanted most. It is therefore absolutely necessary to criticise every new proposal for the extension of irrigation with the greatest care, from a financial point of view. And in order to do so, we must acquaint ourselves with the pecuniary results of the works already constructed.

We will on a future occasion review the general financial results of irrigation works as shewn in Mr. Buckley's book, but for the present we must confine ourselves to the history given of the undertakings not taken in hand directly by the State. We hear a good deal at present of the necessity for encouraging private enterprise, and in 1858 it was thought politic to do this in the practical form of a guarantee of five per cent. interest on capital to the Madras Irrigation Company. This was certainly an excellent scheme for the investors who obtain more than the usual interest for money in Government securities, with the patronage of management and the chances of any surplus which there may accrue. The result to the public has not been beneficial. While the other irrigation works in Madras, constructed by the direct agency of Government, have been extraordinarily successful, yielding an average

of twelve per cent. a year, that of the Company has never paid anything and cleared its own working expenses in one year only. The works cost more than twice the amount of the estimates, and when finished were open to serious strictures in details. They were practically complete in 1871, and in the following year the Madras Government reported that to pay the guaranteed interest it would be necessary that they should irrigate seventy-eight acres for every one irrigated at that time. The Secretary of State for India wrote in 1872 that "no public advantage whatever, but on the contrary, very serious disadvantage, has accrued from the recourse which for so many years continuously has been had to the co-operation of the Company, in the construction of irrigation works; and there is no reason for supposing that anything would be gained by either the Government or the people of India from further perseverance in the same course."

The East India Irrigation Company was more spirited, inasmuch as it undertook its work without a guarantee. Government engaged to pay the cost of acquiring the land and to collect the water-rate, the Company in other respects acting for itself at its own risk. Sir Arthur Cotton made the designs, and the estimate was for a net profit of thirty-one per cent. The field of operations being Orissa, in which there is an ample rainfall, which does not fail more than once in a century, it will be apparent that the investors, and those who made the estimates, belonged to the class known as sanguine projectors. Water was available for irrigation in 1865, but no one would voluntarily take it at the price offered, and there were scandals as to its being forced on those who did not want it, but were made to pay for it, on a futile pretence that they had "used" it. The receipts were almost nothing, and did not approach the working expenses, which were extravagant. In 1868 Government came to the rescue, buying up the works almost at cost price, though they were at the time a losing business, and worth nothing in the market, except what the land might fetch and the blocks. The net result up to the time to which the accounts are given by Mr. Buckley, April 1877, was a loss of nearly a hundred thousand pounds on the working expenses, besides interest and compound interest, if the latter should be wanted. Great pressure has been brought to bear on the cultivators to make them take the water at about one-fourth of the price at first demanded, which seems to be its real value, and with some success. It seems, however, doubtful if the present receipts, which but slightly exceed the working expenses, can be maintained. The obvious conclusion is that private enterprise, where it has been applied to the formation of irrigation companies, has been unfortunate, the only two such associations formed having hit upon works which must have resulted in the bankruptcy of the Companies, had they not been saved by a Government guarantee or assistance. The loss has fallen on the tax-payer.

IRRIGATION IN INDIA.

FROM time to time the old proposal is brought forward of employing the wind for the purpose of lift in India. Various inventions have been patented in this view; the utmost ingenuity has been displayed; but the great desideratum has not yet been attained, of rendering the motive power constant.

The fact is that irrigation by lift is the agricultural stand-by of this continent. Flow of irrigation is a delightful luxury, but it is not everywhere attainable, nor always available. But the zemindar who has his well is independent of all circumstances: he possesses that which under any stress, will give him ten to fifteen acres of cultivation. Of course there are large tracts in India, at any rate in the Punjab, where well irrigation is not possible, owing to the depth of the water below the surface. In such regions, if the rainfall is also inadequate (as it is every where above 76° latitude and between 30° and 23° longitude) canals are absolutely necessary and profitable. "In Sind," write the Famine Commission, "we find a large province in which, without irrigation, agriculture and population would be alike impossible; but the province which, with this protection, has 1,800,000 acres of cultivated land has reached, a fair condition of prosperity, and gives complete evidence of far greater capacities for progress in future." Now in Sind well irrigation is only possible along the immediate banks of the Indus, as canals are the sole resource. But where the rainfall is ordinarily not inadequate, a zemindar whose holding is protected from drought by a well, is independent of canal irrigation. When water is within from 25 to 40 feet of the surface, such a well will supplement rain irrigation in from thirty to forty acres, and will absolutely protect, in case of failure of rain, from ten to fifteen acres. The cost of such a well is from three hundred to five hundred rupees. The bullocks and men that are employed thereon, have to be maintained in any case for agricultural purposes, and the additional cost in this respect of a twenty-five feet in depth well, with Persian-wheel, is perhaps one man at Rs. 50 a year and a pair of bullocks. Estimating the prime cost of the latter at Rs. 80, and their period of work at five years, and allowing something for their feed (which, however, they really raise for themselves) such a well costs about Rs. 2 an acre for maintenance and Rs. 6 an acre capital cost. For a forty feet in depth well both items may perhaps be doubled. Even in the latter case the cost is by no means so great as that of flow irrigation. The cost of the latter in water-rate is from Rs. 2 to 6 an acre, added to which are the perquisites demanded by the various officials of the Irrigation Department. These cannot be estimated at less than a rupee an acre, putting aside the actual bribes paid for value received in the form of illicit irrigation. The water advantage rate on canals is balanced by the special irrigated rate paid by well lands; nevertheless, the actual water charges on the former may be assumed, on an average, as about double the cost of well irrigation. Of course when rain falls it is worth much more. In such case the cultivator with canal water will get a crop from his whole forty acres instead of from only fifteen, but failure of rain is exceptional in the greater part of the Indian continent, and to provide against it, at the cost of perennial canals, like Sir Proby Cautley's vast work, is not desirable when the same object can be effected by merely lending money at interest for the construction of wells.

The great irrigation measure of the future, then, should be the extension of wells. Two things at present stand in the way of such extension by the unaided efforts of the agriculturists. One is the lack of capital and the high rate of interest charged by money-lenders. The other is want of security of tenure in the cultivators of the soil, and the apathy, short-sightedness, and greed of Indian landlords. Both these matters have been dealt with in great detail by the Famine Commission in the second part of their interesting and most valuable report. Lack of capital among the agricultural classes can only be remedied by prosperity consequent on the improvement of agriculture; but the high rate of interest charged by the bunnia, which is the consequence of bad security, might certainly be lowered by such measures as the Commission recommend. "The aim of all remedial measures as regards the land-holder, should be to make his dealing with his banker fair and open, and while protecting him from extortion or oppressive measures of coercion, to constrain him to pay his just debts to the full extent of his means, but by less cruel and ruinous expedients than imprisonment and the sale of all he possesses. The means available to these ends are cheap and accessible Courts which shall give full consideration to the equity of every claim and a simple method of recovering debts." "As a supplement to cheap and accessible Civil Courts, the assistance of the revenue officials in the repayment of agricultural debt, is probably the greatest benefit to both debtor and creditor which the Government is able to offer." The revenue authorities, it is proposed, should, in each case of decree, decide what is the amount of owner's profit and of cultivator's profit in the land, and, leaving the zemindar the latter, should collect the former with the land revenue and pay it to the creditor "who would thus be freed from all trouble in executing his decree, and from almost all risk." The risk being thus lowered, it is but reasonable that the rate of interest should be reduced. "A mortgage should not be an agreement entered into privately, and on very onerous terms, between the money-lender, taking all risks, and the landowner, assenting to terms he does not understand, but might with advantage to both parties rather be an agreement openly made between them before the Collector, and on terms sanctioned, and to be enforced, by him. Any mortgage not so

made, would rank only as a simple unsecured debt, and no cognizance of it would be taken by the court which alone would have jurisdiction in respect of landed debts." "Unsecured debts, it is proposed, should not be recoverable from the land, and no claims on the land should be recovered except by the Collector and none except those thus openly arranged before him." Further, he "should be empowered to refuse his sanction to a loan incurred for an extravagant and merely ceremonial purpose, or for any cause but one of agricultural improvement or necessity."

By adoption of these carefully-considered proposals—not merely temporarily and locally, as the Commission tentatively propose, but generally and permanently—the improvident borrowing and debt which is the curse of the Indian agricultural classes, and the clog on all improvement, would be restricted, and capital rendered available for purposes of improvement at a very much lower rate of interest than the 20 to 36 per cent. now "commonly paid by agriculturists." The want of security of tenure in cultivators and the apathy and greed of landlords is also remedied by the proposals of the Commission. "It has always been an accepted principle," they write, "in India that the occupant of the soil is entitled to remain there from generation to generation, provided he pays the portion of the produce which may be demanded from him by Government or by some superior holder or landlord, and this proportion has generally been fixed by local custom." Unfortunately, however, under our rule "English ideas of proprietorship were allowed to obscure the important limitations to which, in India, proprietorship was subject, and a tendency arose for the landlord to become an absolute owner, and the cultivator a rack-rented tenant at a competition rent." The tendency of legislation since 1859 has steadily been to remedy this, but there is much diversity in the law of different provinces. The Commission now proposes that these diversities should be reconciled and that a general legislative enactment should give occupancy rights to all cultivators of 12 years' continuous tenure. It is further proposed that at settlement, or, in the case of Bengal, every thirty years, rents should be fixed, field by field, for the term, and the assessment based on a fixed proportion of this rent-roll. Occupancy tenants falling into arrears should be allowed suspension of demand by the revenue courts on account of accident of season, or, if ejected, should be allowed the value of their beneficial interest in the land. Every form of oppression now common among landlords should be encountered by a special procedure to be devised for the purpose, and illegal distraint especially should be rendered penal. Tenants being thus protected, the Commission would further prevent those with rights of occupancy from becoming in their turn rack-renters. While permitting sale or mortgage of the holding, they would prohibit temporary transfers by enacting that the occupancy rights in the land shall pertain to the person in cultivating possession of it, and shall pass from those who fail to cultivate.

Under these provisions cultivators will have a strong incentive to improve their lands, and will be able to procure capital for the purpose; but this is not alone sufficient, for at present the tenant cannot improve the land without the landlord's sanction. On this head the Commission merely says: "We think that more distinct legal provision is required to secure that every occupancy tenant may effect in the land he occupies material improvements of the kind contemplated in Act XXVI. of 1867, without requiring him to obtain the sanction of his landlord and without endangering the security of his tenure, * * further, every tenant, who is ousted by his landlord for failure to pay rent or other causes, should obtain compensation for unexhausted improvements." This is a matter easily arranged. Every tenant desiring a well or other improvement of his land should have the right to call on his landlord through the revenue courts to construct it. On failure the tenant should be entitled to construct it himself, acquiring thereby, if an occupancy tenant, immunity from enhancement (however near may be the term of the settlement) for thirty years; if a tenant-at-will, a thirty years' lease at the rates paid by the occupancy tenants of the neighbourhood. Such a measure would give an enormous impulse to the construction of wells and irrigation works. It would be perfectly just, for the landlord would have the option of constructing the work himself, and the compulsion placed upon him in the matter would be nothing more than is due in the interests of the two other parties equally interested in the land, *viz.*, the Government and the cultivator.

Finally, the Commission propose that Government should supply money much more liberally and readily than at present for agricultural improvements. The difficulties at present thrown in the way are "the obstacles created by insufficient native subordinates to whom the granting of such advances gives extra trouble; the delay and expense of the initial procedure, under which the first application has to be stamped, the bond for repayment stamped and registered, and a minute and troublesome inquiry has to be made into the nature of the applicant's tenure and its value; the necessity of paying interest, which is usually fixed at 6¼ per cent. per annum; the small number of years over which repayment may be spread, and the consequent largeness of the annual instalments; the early date at which they begin to fall due even before the improvement has begun to realise a profit; and the rigidity of the rules for punctual repayment." We consider that the loan should by law be secured on the applicant's interest in the land, and be recoverable by sale of that interest like an arrear of revenue. With this precaution all present difficulties in the way of making these advances might be swept away, as the Commission proposes; and certainly as the money is to be applied to improving land in which the Government is directly interested, the interest might be fixed, as the Commission suggests, at only so much as Government itself has to pay for the money: the instalments might be spread over a period extending even to twenty years, and commencement of their recovery might be postponed till the work was completed and gave results.

In the words of the Famine Commission, "there are numerous localities in which wells might profitably be made, but in which their construction has hitherto been prevented by the absence of capital or by circumstances connected with the conflicting interests of co-proprietors and the unsatisfactory relations of tenants and landlords. In such cases the only way in which it is likely that wells will be constructed, is by some systematic action of the Government which may either supply the capital or overcome the difficulties which stand in the way of mutual co-operation." We have reviewed the proposals for rendering the capital available both from private money-lenders and from the Government treasuries. We have shewn how the Commission propose so to increase the interests of the cultivator in the land as to render him desirous to improve it, and we have suggested that in default of the landlord's effecting improvements, even the tenant-at-will should be permitted to do so. The Commission further propose "to stimulate well construction by extending the practice of Bombay and Madras to Upper India, so far as to rule that the assessments of land irrigated from a permanent well should not be liable to enhancement on account of the well at any revision of the settlement provided the well is kept in efficient repair." We have stated, however, that we would limit this protection to the period of thirty years. In all this we have not gone so far as might appear from the subject with which we commenced our article. Irrigation by lift is incomparably the most important factor in India's future agricultural progress, and to this subject all that bears upon wells, whether the improving of the credit of the ryots who may construct them, or the facilitating of their working by harnessing thereto the winds, is equally cognate.

TRADE WITH AUSTRALIA.

MUCH attention has been drawn of late to the subject of opening up commercial relations with the Australian colonies. This has, of course, been the result of the late Sydney and Melbourne Exhibitions. These were directly intended to assist in increasing the commercial relations of the colonies with the rest of the world. Busied as we were at the time of the Exhibition at Sydney with the Cabul war, and partly, doubtless, owing to the novelty of the proposal as well as incredulity at the wealth and greatness of Australia, which before this

was but imperfectly known even to the best informed of us, we made at first a very poor shew indeed. Had the industrial and other trade resources of India been only such as they appeared at the Sydney Exhibition, they would not have attracted any further attention in Australia. The Indian court was, we are informed, simply the most disreputable one—perhaps it would be more correct to say the only disreputable one—in the building. This was so noticeable that attention was repeatedly drawn to the subject in the press there, but nothing came of that. But the Melbourne Exhibition came to supplement the Sydney one, and the Indian Government, being thoroughly roused by this time to the importance of the interests involved, made a real attempt to make a show, and actually did succeed. So well indeed did it succeed, that the Indian court was reckoned one of the best, and a full account of it is yet a thing we have not had. What with the interest of the show, and Mr. Buck's inherent energy, the Indian court became towards the end the best known and appreciated of any. Public attention thus being drawn to Indian goods, the subject of Indian trade with Australia came to the front, and has attracted much attention since both in Australia and in India. It may be well therefore, now that the exhibitions have closed, to take a glance at the subject of Indian trade with Australia, and how it may be furthered. At one time, during the early history of New South Wales, the trade, for those days, was pretty large. There are old merchants now living in Sydney who can state that they had a brisk and profitable trade with India in days gone by. In the aggregate it was not nearly so large as at present, but the population there was very small and the trade passed through only a very few hands. The complaint, not well founded as we shall show, now is that there is hardly any trade with India. But it is to be remembered that for a population then of 300,000 souls, there is now one of nearly three millions; that for one or two leading mercantile firms then, there are scores now; that for one colony then there are half a-dozen now; and that for a trade then with only India, Great Britain, and the Madeiras (for wine), there is now a traffic as widely and generally diffused as the countries of the globe. Australia trades now not only with England and India, but very largely with China, California, the South Sea Islands, Mauritius, and even to some degree with Japan, Germany, Singapore, and the colonies, one with another. In this general diffusion of traffic, the trade with India could not of course keep to its old proportion. Hence it is that though in the aggregate the trade with India in gunny bags and cornsacks alone now outweighs the entire former trade with India, it is true that there is much room for increase of traffic. In one article, however, notably the trade has actually declined. Though there is no good reason why it should have done so; we refer to the trade in Australian horses for the Indian market.

As we state above there is a large amount of trade done at present, larger in the aggregate than at any former period. At the top stands the import into Australia of gunny-bags and cornsacks. These are of course very largely in demand in all the Australian colonies. Not only are they wanted for the whole wool trade of Australia, but the smaller and coarser kinds are being used everywhere for sugar, potato-bags, and a variety of other carrying purposes. Next to gunny-bags and cornsacks comes rice. There is a great import of rice into Australia, and although still it is used mostly after the English fashion, it is more largely consumed than in England for each head of the population. Besides, there are some fifty or sixty thousand Chinese in the different colonies who all largely subsist on rice. After these come Indian spices and condiments, and some other articles such as indigo and opium; and, probably last as well as least, Indian tea. In return for these Australia exports to India a very few horses, a little pearl-shell by way of Singapore, small quantities (for the trade in it is just beginning) of blue metal stone cubes for building or road way purposes a very little tinned meat, and a quantity of gold sovereigns.

It will be seen from this that the balance of trade is in favor of India. Indeed, Australia requires, and will always want, a good many Indian articles, and the number enumerated above as imported from India may be increased. For all this Australia cannot for a long time to come make any return save in horses, blue-metal, and gold. Of course, the trade in pearl-shell may increase, and timber from Western Australia, and coal from Sydney may be exported to India. But from all appearances the balance of trade will continue in favor of India. The subject, thus, is one of considerable interest to our merchants and to India generally. There can indeed be no two opinions on this subject. Here is a poor and populous but producing country, and there we have a wealthy though as yet, small community still annually increasing in numbers, who require and will take many of our goods. It is, however, to the interest of both that the trade should increase. We undoubtedly want here a finer breed of horses, beyond mere cavalry requirements. The sorry specimens of horse-flesh to be seen in India, are a disgrace to any country. So we may note too, in passing, of the miserable specimens of sheep, horned cattle, and even dogs. It will do India good to have a better breed of horses. It will benefit the country, while paying the pockets of Australians, to have the blue-metal cubes for roadway and building purposes. So much money now sunk in brick and shabby soft sandstone would be saved here to us and the country. And were Australia to take to Indian tea, it would benefit both India and Australia. The trade in tea alone might amount to millions.

The trade of India with Australia is both stable and progressive. It began more than half a century ago, has considerably increased, and can only attain to larger dimensions. And there can be little doubt that new articles, such as linseed, safflower, &c., and even we may say Indian corn, will gradually take their place among the others. Tea alone has a doubtful future, notwithstanding the late March sales, which for certain reasons offer no criterion to base any hopes upon Indian tea with all its purity, strength, and flavour, will make its way in Australia only under certain conditions which we do not see availed of. The Indian Tea Syndicate will have yet to rouse itself to obtain a practical knowledge of Australian ways. This, however, is too extensive a subject to take up at the end of an article.

EDITORIAL NOTES.

MADRAS has invariably taken the lead in matters agricultural, and it is perhaps in accordance with the fitness of things that her agricultural students have been the first to move in the direction of obtaining official recognition of their labours in the shape of a degree. The arguments they use are no doubt true as regards agriculture in the abstract. Agriculture is, no doubt, a most important subject of study, perhaps, in this country, *the* most important. For this very reason therefore, it behoves these students to avoid everything that might tend to bring their studies into disrepute. It may be argued that the bestowal of a degree would not do this. One thing it would do, it would bring to the classes a large number of students whose end-all and be-all would be the degree. Agriculture is a thoroughly practical subject, and partakes more of the nature of a great industry than a science. We do not for a moment wish to undervalue the science necessary to make a good agriculturist, but we affirm that what he requires most is being thoroughly grounded in the practical department of his work. When young men at home learn their professions, which they do by means of an apprenticeship of so many years, they become journeymen, that is to say, they are supposed to know their business thoroughly. This is the summit of their ambition. Degrees do not lie in their line, but only in connection with what are popularly known as the "learned professions." We trust, therefore, for the sake of the students themselves, and for the future success of the agricultural schools, that the Government will not grant their prayer.

ON this subject the *Madras Standard* says :—

"If the Senate deem it fit to grant the prayer of the petitioners, it will, we think, make the Agricultural College more attractive than it is to the youth of this and the other presidencies."

This is no doubt quite true; the college would be more popular and attractive. That, however, is not the object of the college. The granting of the prayer would not draw together a better class of men, men whose sole aim was to become good cultivators. The future students might be more numerous, but they would

largely consist of young men, who had little further desire in life than to be able to write L. Agri. or some such rubbish after their names.

To get rid of caterpillars, an American agricultural journal recommends the following :—

"One pound of common salt dissolved in eight gallons of water will make a brine that will kill currant catterpillars. It should be sprinkled on the shrubs with an orchard syringe in the form of a spray. A watering pot with small holes in the nozzle of the spout will answer the purpose. Care should be taken not to dissolve a greater proportion of salt than that named, lest the brine injure the leaves, fruit, or other vegetation."

An esteemed correspondent from the Madras Presidency writes to us as follows :—

"In your issue of the 1st June, I find the following sentence :— The providing of manures for their crops, is quite beyond the ability of the ryots." Why is it beyond the ability of the ryots to manure their land with night-soil? Surely that is not too expensive for them. You seem to overlook the examples of China and Japan. History affords no example of an exception to the rule that the careful use of human excrement as manure ensures prosperity, and that its waste entails distruction." We have not overlooked "the examples of China and Japan," and have no doubt that if the ryots could be induced to utilize night-soil in this way, much good would be effected. The operations of caste, however, are so all-powerful in many parts of India, that we have not been inclined to include night-soil as a manure in connection with Indian agriculture. The Chinese and Japanese, we know, are not so fastidious in this respect, and have brought agriculture to a high pitch of perfection principally owing to their universal use of this agent. That the Indian cultivator can be got to use it, we have no doubt, with the examples of Poona and Umritsur before us. This, however, will be after a long and hard struggle. Municipalities would materially aid this good work, and largely benefit their own exchequers, if they would turn their attention to *poudrette* manufacture. We are obliged to our correspondent for bringing this to our notice. He will see, however, why we did not consider night-soil as at present within the range of manurial agents.

Mr. Darwin's next work will be looked for with much interest. It is on "The formation of mould through the action of earth-worms." No one can have failed to observe how these useful creatures turn up the soft mould and leave it in little pyramids all over the ground, especially after rain. Mr. Darwin, will, as a matter of course, make his subject interesting.

"The Columbus (Miss.) *Patron* predicts that in less than ten years the bulk of the cotton crop will be converted into yarns within sight of the fields in which it is grown. This may be more than will be realised, but there is but one reason why cotton manufacturing should not be one of the most important industries of the South—that is, the neglect of the South in taking hold of it." Exactly, almost everything seems possible in America. Here, we only go in for new things after the most careful investigation, and seldom in fact until success has been assured at the expense of the investigators of other countries. There is no reason why every yard of cloth used by the natives of India, should not be made by them here. No reason, save apathy and want of enterprise. We have cheap cotton and cheap labour, all we want is enterprise.

This is the way some Government encourage new industries "A bonus of $25,000 is offered by the Municipality of Beauharnois, in Canada, to any company which will start a beetroot sugar manufactory." The only parallel to this in India, that we can recall to memory is the offer of a similar sum, £5,000 for a *rhea* cleaning machine, a couple of years ago. But this was a very perfunctory affair. Almost all exhibitions complained that the raw material supplied them was of the very worst quality, and short in quantity, and altogether the trial was a very unsatisfactory one. The Canadian Municipality will, doubtless, be called upon to pay this bonus, and once the industry is fairly started, it will require no eleemosynary help. There is plenty of room for the establishment of several sugar factories in India, few countries being so favorably situated for the growth of the cane, and as we have frequently pointed out, labour is a cheap item, if the vicinity of the presidency towns is avoided.

As a contribution to the literature of the American wheat crop, we quote the following :—

"The Kansas *Farmer* says :—The general outlook for the winter wheat crop is considered favorable, with a prospective yield about the same as that of last season.

There are immense tracts of land in India, known under the designation of unculturable. Most of this is culturable, and almost every acre is at least able to bear fruit. Why then should we not utilise their vast tracts by planting out fruit trees. See what is being done in America. "It is reported in the *Engineer* that the Philladelphia capitalists who are about to reclaim the immense tracts of land in the State of Florida known as the Everglades, have completed their contract with that State, one of the main features of the scheme being the building of a ship canal across Florida. This project almost equals in importance that of reclaiming 12,000,000 acres of rich land. It would not only shorten the distance between the American ports on the Atlantic coast and all European ports to New Orleans, Mobile, and all shipping points on the Gulf of Mexico, but it would avoid the dangers to navigation which are experienced on the countless keys and coral reefs off the southern and south-western coast of Florida." Is there any reason why several million acres in India should not be brought with under the plough, or planted or with useful trees as mango, mowha, &c. We are not aware of anything hindering this save apathy. If the Forest Department officers are too busy, or consider such work beneath their dignity, it can be done by contract.

Viewed as a matter of economy alone, the throwing out of the bran is a fatal mistake. From careful experiment it has been found that Pennsylvania farmers claim that equal weights of wheat, bran, and corn meal, mixed together, will produce more weight in an animal than the same aggregate weight of corn meal; that is, 100 pounds of meal and 100 pounds of bran fed together will yield more increase than 200 pounds of corn meal fed by itself as grain food. What is good for farm animals is equally good for human beings in this connection, and there being nothing repulsive in eating the bran mixed with the meal, there is no reason why we should contrive to consume only the white flour. It is now becoming fashionable in some quarters to consume the whole meal as it is called, that is to say, to form the flour, the grain with the husk still adhering is ground. It is more nutritious, more wholesome, and quite as agreeable, and our rejection of the bran is the result of ignorance or pride.

Recent experiments with beans by a French observer M. Pauchon, give the result that to reach the same visible stage of development a black or violet seed absorbs more oxygen than a white or yellow one, though a more rapid germination is observed in the latter. On the other hand, the quantities of carbonic acid exhaled by white seeds are found to be considerably greater than those from the dark, sometimes even double. These differences are considered to prove that dark or violet seeds are better conditioned from a physiological point of view. In the natural state—*i.e.*, when the seeds germinate in light—the conversion of legumin into asparagin must go on much more easily in the coloured seeds than in the others. "The more frequent and pronounced pigmentation of seeds of northern lands is therefore," says M. Pauchon, "a favourable circumstance for the growth of these organisms, under the peculiar light-conditions to which they are subject."

Locusts are playing sad havoc in New Caledonia. The authorities have offered a reward for their destruction, and it is reckoned that 51 millions have been bagged. Some people say it is like trying to bale the sea with a bucket, they are so plentiful.

Dr. Rudal calculates, that the paper produced in the whole world—paper of all kinds, of hemp, of linen, of straw, of jute, of rice, &c.—amounts to 1,800,000,000lbs. Half of this quantity is employed for printing purposes, a sixth for writing purposes and the remaining part for divers uses. The whole may be thus categorised:—For Government purposes, 200,000,000 lbs. are used; for instruction, 180,000,000; for commerce, 240,000,000; for industrial manufacture, 180,000,000; for private correspondence, 100,000,000; and for printing, 900,000,000. For the production of these 1,800,000,000lbs. of paper there are 3,960 manufactories, employing 90,000 men and 180,000 women. In addition, 100,000 persons are engaged in collecting rags.

Mr. Wedderburn's scheme of agricultural banks is just now being discussed by the press. The *Hindoo Patriot* approves of the scheme, but would make them State institutions, and we are inclined to agree with our contemporary. We are averse to the State engaging in any undertaking which can be done by private enterprise; but this is, in our opinion, just one of those schemes which is beyond the reach of private enterprise. The amount of capital required would be so large, that we have no hesitation in saying that it could not be raised, unless by the help of a Government guarantee. This could be got over, we have no doubt, because under arrangements properly conducted, there is such a wide margin for profit, that there should be no difficulty in obtaining, nor any reluctance on the part of Government of granting such a guarantee. It is proposed to ask for a State guarantee to the extent of 4 per cent, and as the loans might safely be made at 6 per cent., there would exist a sufficiently wide margin. The *Hindoo Patriot* says "the ryot will gladly pay 12 or 15 per cent. for State loans." Doubtless he would, but we do not see the slightest necessity for his being charged more than 6. By the business being in the hands of the State, there would not be the same temptation to charge too high, the object in view being to help the ryot, and not to make a profit. With private enterprise, no such philanthropic object would operate as against the obtaining of a good return for money invested. This subject deserves a wider consideration than we can give it in these columns, but we shall return to it.

Recent experiments on this subject with beans by a French observer, M. Pauchon, give the result that to reach the same visible stage of development, a black or violet seed absorbs more oxygen than a white or yellow one, though a more rapid germination is observed in the latter. On the other hand, the quantities of carbonic acid exhaled by white seeds are found to be considerably greater than those from the dark, sometimes even double. These differences are considered to prove that dark or violet seeds are better conditioned from a physiological point of view. In the natural state—*i.e.*, when the seeds germinate in light—the conversion of legumin into asparagin must go on much more easily in the coloured seeds than in the others. "The more frequent and pronounced pigmentation of seeds of northern lands is therefore," says M. Pauchon "a favourable circumstance for the growth of these organisms, under the peculiar, light-conditions to which they are subject."

In order to rightly understand the *rôle* of heat in the growth of plants, it is important to know what part of the heat rays which strike the leaves is absorbed by them, what part is thrown back and scattered, and what part passes through them to lower organs. An inquiry of this nature has been recently made by M. Maquenne. Of his method we will merely say that he used, as constant heat source, a Bourbouze lamp (in which a platinum wire is kept glowing by a regulated mixture of coal gas and air); and for some experiments with low temperatures he employed Leslie's cubes. The results of the research are briefly as follows:—1. All leaves scatter a part of the heat they receive vertically to their surface; with the Bourbouze lamp this diffusion is about 0·25 of the whole heat, with the Leslie cube a small precentage. 2. Generally, the under side scatters more than the upper, but the reverse sometimes occurs. 3. Leaves absorb a good deal of the heat from the Bourbouze lamp, the absorption being due to the presence of absorbing substances, especially chlorophyll and water, in the tissue, and to the diffusion taking place internally at the surface of each cell; it is generally greater at the upper side than at the lower. 4. Thick leaves absorb more than thin leaves. 5. The absorptive power of leaves for the heat of boiling water is very nearly equal to that of lamp-black. 6. Leaves let heat pass through better the thinner or younger they are. 7. The radiating power of leaves with a great excess of temperature is pretty near that of lamp-black; it decreases a little when the inclination increases. 8. The absorptive power of chlorophyll is, on an average, equal to that of water for rays of the Bourbouze lamp, and increases proportionately to withdrawal, in one direction or the other, from the heat *maximum*.

The twelfth volume of the *Encyclopædia Britannica* just published contains an article on "India-rubber," by Messrs. E. M. Holmes and T. Bolas. We shall give this ere long, but mean while we give the figures for yield of caoutchouc from different varieties of trees. Para (*Hevea Brasiliensis*) yields 6 ounces in 3 days, the juice yielding generally 32 per cent. of its weight as caoutchouc. For Ceara *Manihot Glaziovi*) the yield is not given. Central American (*Castilloa elastica*): a tree 20 to 30 feet high to its first branches is expected to yield 20 gallons of milk, each gallon giving about 2lbs. rubber. Assam rubber (*Ficus elastica*); about 20 oz. milk collected in August gives 15 oz. caoutchouc, but the precentage is sometimes so low as ten per cent. From February to April the milk is scantier but richer in caoutchouc. Borneo rubber (*Urceola elastica*) yields sap in three years. Rangoon rubber (*Chavannesia esculenta*) yields $3\frac{1}{2}$lbs. at 7 years. This is certainly very encouraging.

An American agricultural journal has the following mode of testing the vitality of seeds:—

The vitality of seeds may be very easily tested before the time of planting arrives. Simply place a few of each species or variety on a piece of moistened flannel, folding the flannel together, and allowing it to remain in some place near the furnace or kitchen range for a day or two. Those seeds that have lost their vitality will, in a few hours, turn dark or mouldy, showing unmistakeable signs of decay. It is a law that pervades all organic matter, vegetable and animal, that the moment it ceases to live, disorganization begins. A dead seed, or a dead animal or vegetable, soon decays; but one containing the vital principle withstands the action of the elements for years.

Mr. L. Ordega, Consul-General of France at Trieste, has furnished, under date of August 10, 1880, some statistics relating to the amount of gum arabic which arrives at Trieste from Africa. The total importation and exportation during the years 1877, 1878, and 1879, was as follows:—

		Importation.		Exportation.
1877	...	2,695,100 kilos.	...	2,707,600 kilos.
1878	...	2,726,300 „	...	2,796,400 „
1879	...	4,638,400 „	...	3,080,900 „

The gums are divided into thirty-two grades, the prices of which vary from about 75 dollars for the best, to as low as 13 dollars per 100 kilos. for the commonest kinds. The available stocks during 1877 amounted to 1,700,000 kilos., but, in 1879, they exceeded 3,600,000 kilos., and even this enormous reserve was hardly sufficient to satisfy the demands from the various markets of Europe. On August 1, 1880, the stock on hand at Trieste was as follows:—

				Kilos.
Arabic	...	...	...	387,000
Ghizira	...	...	...	57,000
Sennary	...	...	...	1,400
Suakin	...	...	...	313,000
Gedda	...	...	...	79,000
		Total	...	838,000

The construction of new routes has rendered the transport of the Suakin gum more easily from its place of origin to the port of debarkation. Owing to the interruption of communication caused by certain rains called *kharif* in Egypt, no arrivals whatever from Suakin reached Trieste during the whole of last October.

THE Department of Agriculture estimates there are 1,000,000,000 pounds of butter and 300,000,000 pounds of cheese made annually in the United States. At 27 pounds of milk for one pound of butter, and 9½ pounds for one pound of cheese, the total amount of milk used would be 29,850,000,000 pounds; add 41 per cent. of the product for consumption, the total production is 60,952,325,000 pounds. The caseine in the milk used for making butter, if utilized for cheese, would produce annually 1,800,000,000 pounds.

COTTON manufacture in the United States is assuming huge proportions, and our American cousins are already formidable rivals in the greatest of our English trades. There are now at work in America 10,931,405 spindles, consuming 1,586,481 bales of cotton which we may take to produce—at 400lbs. of clean cotton per bale—934,592,400lbs. of yarn, per annum. To weave this the Americans have 231,159 looms the spindles and weaving together giving employment to 181,628 work people. To institute a comparison with our English trade, we may mention that we had in the United Kingdom at the end of 1878, 44,205,690 spindles and 514,911 looms, worked by 482,903 hands. In other words, while we had two and a quarter times as many looms and four times the number of spindles as the United States, we worked them with little more than two and-a-half the number of operatives; a proof this, of the superiority of the English operative over the American.

THE little kingdom of Sweden, with less than one-twentieth of the area, and scarce one-twelfth of the population of the United States, appropriates more than three times as much to the promotion of her productive interests as does the Government of the United States.

A DISCOVERY which promises to have important results has lately been made by a scientific gentleman in the island of Reunion, situated near the Mauritius. He claims to have succeeded in solving the problem of extracting vegetable fibre from the aloe or other leaes in an economical manner, and one which can be generaly adopted. The principal features of the invention are as follows:—The leaf is first placed for ten minutes in a bath heated to 95° Fah., and then removed to a second bath of water at its normal temperature, in which some inexpensive chemical substance (not yet made public) has previously been mixed. The leaves are allowed to remain some little time in the second bath, after which it is said that the fibre can be washed out by women or children without any trouble. A patent has been taken out for this process by its inventor. As the aloe is known to grow as freely as weeds in this colony, this discovery would appear to present the means of establishing a new and profitable industry for a very large proportion of our population. This is a subject of vast importance to India, which may be said to be a land of fibres. The aloe flourishes everywhere, and in India may almost be called a weed—as a rule it grows wild, and is never planted except for the formation of boundaries. If this invention turn out a success, the industry of manufacturing aloe fibre into ropes, matting, and cloth will receive a powerful impetus.

"A MERCHANT brought us a branch and a box of seed the other day taken from a tree which had yielded an abundant supply of milky juice likely to be of value when prepared as India-rubber. 'W. F.' writes:—'The branch you sent me is well known to me by its Sinhalese name Kirripælla, and is the Ficus infectoria. See what I say about it in Mendis' list No. 45:—'Kiripælla, Ficus infectoria, Will. Urostigma do. Miq. Thw. En. p. 265. C. P. 3,083. The bark of this tree is used by the natives for chewing with betel, but the timber of this tree and of most of the other species of Ficus are scarcely ever used for any valuable purpose. They are all nearly worthless. All the figs and we have about 23 species in Ceylon, are natives, but is the rubber from them worth the expense of collection?' That is just the point which only a practical test can settle: our mercantile friend is right in trying the experiment." This extract is from the *Ceylon Observer*. There are doubtless many trees growing wild which yield a milky juice which would form a good substitute for India-rubber. The common villages as a rule know all about them and a little intelligent inquiry would elicit much useful information.

THE export of this dry fruit, if we may so call it, is attracting a little attention at present. The Divi Divi plant grows in many of the outlying villages of Madras, and up to a recent date no one cared to collect the dried fruit. Now, however, that it is found to be a valuable article for tanning purposes, large quantities are shipped to Europe, and in fact many persons have begun to pay some attention to the cultivation of the Divi Divi plant. A consignment of 88 bags was shipped to London in the steamer *Duke of Buckingham* last month, and large shipments would probably go forward if greater attention were paid to the cultivation of Divi Divi.

FEW crops are so valuable as Divi Divi. It is the *cesalpinsa coriaria* of botanists, and a member of the Babul family a pod grows as the tree similar in appearance to that of the Babul, and the tannin so much valued by leather curers is in this pod. The trees should be raised in a nursery from seed, and planted out about 15 by 15 feet, thus giving 173 trees to the acre. For the first two years they must be guarded for cattle treading on them, after that they require no looking after till the seventh year, when they bear pods, and speedily pay their way. An acre in full bearing will yield fifty cwts of pods which are worth in London fifteen shillings per cwt, and as the cultivation and care cost literally nothing after the trees are in bearing, it is a most profitable crop. Another good quality it has, it will grow on almost any soil.

THERE is a belief among up-country natives that the flowering of the bamboo and an abundant mango season portend great sickness and famine. It appears that the same belief holds good among the Burmese. The *Rangoon Times*, alluding to the subject, remarks:—"Both these beliefs prevail in Burmah and among the Burmese, and what is more to the point, Burmah may be added to the list of provinces where this year the bamboo has flowered, and the mango crop has been exceptionally abundant. And the belief among the Burmese at the present moment is that great famine and pestilence are threatened. The fact remains that the prevailing beliefs among the Burmese are, as in India, that the flowering of the bamboo betokens famine, and the abundance of mangoes, pestilence; and these beliefs are at the present moment productive of no small amount of anxiety and foreboding among the people."

EVERY thousand pounds of fat cattle sold from a farm carry away one and-a-half pound of potash (neat cattle two pounds), which must be restored in order to keep the land in as good condition as it was before commencing to raise or feed the stock. Wood ashes, which are usually permitted to go to waste in the West, contain a large percentage of potash.

IN the course of a recent lecture at the London Institution on the above subject, Sir John Lubbock, M.P., remarked that the seed of the Sycamore, the Maple, the Elm, the Birch, the Pine, the Fir, and the Ash was attached to a leafy wing and carried to a considerable distance. In many cases the fruits and seeds were dispersed by animals. The animals were attracted to them by their brilliant colours, as in the case of the cherry, the peach, the raspberry, and the strawberry. These coloured fruits formed a considerable part of the food of monkeys in the tropical regions of the earth, and we could not doubt that these animals were guided by their colours, just as we are guided in distinguishing ripe and unripe fruit.

The fact of the seeds being a temptation to such animals as mice and squirrels was not altogether a disadvantage, as the seeds were thereby often carried and buried in the ground, and they could very well afford to spare a few seeds for the squirrels and the mice. Some seed-vessels, such as the Martynias and some others, had very formidable hooks attached to them, which had been known even to kill a lion. These hooks adhered to the skins of animals, and the seeds were thus dispersed.

THE subject of opium is at present occupying the public mind, both here and at home. As to the morality of our government being concerned in the intimate relation existing between it and the monopoly; we are not concerned here to consider. The following table shows the average outturn per beegah in both agencies for the last five years:—

	Behar		Benares.	
	Seers.	Chittacks.	Seers.	Chittacks.
1875-76 ...	5	13¼	6	4
1876-77 ...	4	14¾	6	9
1877-78 ...	3	5½	5	1¾
1878-79 ...	3	15½	5	7¾
1879-80 ...	4	10¼	4	0½

The following statement shows the cultivation and produce in each agency for the last two years:—

Season.	Land sown for cultivation.	Net cultivation.	Produce at 70° consistence.
Behar.	Beegahs.	Beegahs.	Mds. s. c.
1878-79 ...	500,371	415,289	41,268 1 4½
1879-80 ...	473,550	461,086	53,593 23 1
Increase ...		45,797	12,325 21 12¾
Decrease ...	26,821	......	......
Benares.			
1878-79 ...	416,015	395,820	56,636 35 8¼
1879-80 ...	451,641	438,531	35,475 37 0¼
Increase ...	35,626	42,711	......
Decrease ...	......	......	11,160 38 8

From this it will be seen that the crop is much like other, very fluctuating as to outturn. It is a crop which the cultivators grow readily, and if Government think of dissociating themselves from the monopoly, they will naturally fall back on an excise duty pure and simple, and this after all will perhaps be the best thing that could be done. Where it can be avoidid at all, monopolies should be done away with.

The success which has attended the experimental shipments of ripe fresh fruits from Australia has set the West Indians on their mettle, and several planters have turned their attention to the cultivation of oranges, pine-apples, bananas, and other fruits, especially for shipment to Europe. America has hitherto been the chief customer of the West Indian Islands for fresh fruits, but there is no reason why England should not share in the fruit produce of her nearest tropical colonies. At the present time he trade in pine-apples is pretty well monopolised by the Bahamas, from whence we receive the cheap fruits which are displayed in a more or less damaged condition on the costermongers' barrows in the streets of London during the summer months. But if more care were taken in selecting and packing the fruit, pine-apples might be received in excellent condition from all the West Indian Islands, and not only pine-apples, but bananas and oranges. The greater expense which would be incurred by a little more care in packing the fruit, and the additional cost of freight, would be more than covered by the higher prices which would be realised for ripe oranges, for instance, which could be sold at the time when such a luscious fruit would be most highly appreciated, *viz*, during the summer months, and at a time when the ordinary supply of European oranges would not be in the market. One enterprising cultivator in Jamaica, who has lately taken to growing pine-apples for export, has realised as much as £80 per acre. The trade in bananas is also increasing, at least, so far as Jamaica is concerned, and last year nearly half a million bunches were exported from that island, valued, at over £38,000. In the case of oranges the value exported last year from Jamaica was over £11,000. Is there absolutely no interprise in India?

A Bombay contemporary says:—"The Punjab has long had the reputation of being a great wheat producing country, but as yet it has not taken any conspicuous place in the matter of exporting beyond sea." This is easily explained, the Punjab is a great wheat-producing country, and the reason why it has not taken a conspicuous place in the matter of exporting beyond sea, is that the railway freight from the Punjab to the sea, is almost prohibitive. The American exporter can convey his grain from the grain-producing states to Liverpool for less than the Punjab wheat costs to convey to the seaboard. This, and we believe this alone, prevents the Punjab from taking a prominent place among grain-exporting districts.

The following are the reports on the state of the season and prospects of the crops for the week ending the 15th June 1881:—"With the exceptions of Sind and Guzerat, rain has fallen in all the reporting districts and states, and it seems clear that the rainy season has now generally set in. The fall has been especially heavy in Burmah, Assam, Eastern Bengal, and the Central Provinces. In a few districts of the two provinces last-named the wet weather has, to some extent, retarded sowings; but preparations for the autumn crop are now in active progress in most parts of the country. Agricultural prospects continue good. No information has been received from Mysore and Coorg, or from Rajputana."

We have received a copy of a memorial which has been forwarded by the students—past and present—of the Sydapet Agricultural school, to the Senate of the University of Madras, praying that some degree may be conferred on successful students in the Agricultural College. We are afraid that this memorial affords practical proof that the real objects of such colleges are misunderstood. An agricultural student is not so much like an ordinary university student, as an apprentice to a trade. When an apprentice serves his 3, 5 or 7 years, he is supposed to be thoroughly well posted up in his business, but it never enters into his head to ask for a degree, with its accompanying insignia. The mistake arose from calling it a college. It ought to have been called a school. The agricultural students will, we fear, derive little benefit from their attendance at this useful institution, if they make a degree a *sine qua non*, or even a desirable accompaniment to their curriculum.

On the subject of agriculture, the *Pioneer* tells us that Mr. E. C. Buck, as was confidently expected, has been appointed Director-General of Agriculture for India. We hail this appointment with satisfaction. With Mr. Buck's well-known and properly directed energy, we may hope for better days for the cultivators of India, as we trust the object of the department will be to avoid all hobbies, and to direct attention to the most comprehensive measures for the benefit of the great bulk of the people, who are the agricultural classes. It is not for us to formulate a line of policy for the new department, but we may be permitted to express a hope that only schemes of practical utility will occupy its attention. The *personnel* of the department will doubtless be as well selected as the head has been, and if so, nothing but good to India can result.

The introduction of opium cultivation into Persia, which took place a few years ago, has proved of great benefit to that country. Efforts are being made to increase the area under crop. The great difficulty in the way being the want of irrigation, and as the people are finding the industry a profitable one, they will doubtless contrive to get over this difficulty. The *Civil and Military Gazette* says on this subject:—"Yezd is said to be capable of producing very fine opium. The possible competition of Persia has sometimes been dreaded by politicians who lament what they call the instability of the Indian revenue from the drug. But the best authorities on the subject say that Persian opium is on the whole as inferior as the Chinese drug. So long as this is the case, the Indian article will find its millions of eager customers in China." We have no wish to be pessimists, but there is no getting over the fact that Persian opium is steadily increasing in favor with the Chinese consumer. A very few years ago it was only worth about half the Indian drug, now the latest quotations are as follow:—

Malwa, old	...	$ 710	to	720
Do., new	...	660	„	...
Patna	...	570	„	572½
Benares	...	567½	„	570
Persian, best	...	560	„	565
Do., low	...	435	„	535

These prices seem to point to an early assimilation, in point of value, between the Indian and Persian varieties.

The United States Commissioner of Agriculture proposes to test the tea-producing capacity of the South Carolina soil. Two

hundred acres near Charleston have been leased for twenty years from a gentleman much interested in the project, and 17,500 tea-plants will be set this season. The experiment is in charge of a gentleman who for many years was engaged in tea culture in India. The Commissioner avers that, in three years' time he will have as fine a crop of tea as ever was raised.

Yes, this intimation is not by any means new. We have heard it before, and we recently learn that an old Assam planter has actually manufactured a sample from the American leaf. We have all along held the opinion—and we do not even now see occasion to change it—that tea will never become on American industry—at least so far as the Cotton States are concerned, we are unable to speak with the same confidence regarding the pacific States, as we are without information as to the climate and rainfall of those States. That tea will grow in America we do not doubt, or for the matter of that we see no reason why it should not grow in the southern counties of England, but the question is not one of absolute growing; it is a commercial one, and we have to ask, will it grow to pay and here we at once find that the rainfall of America being deficient, the leaf will not be produced in sufficient quantity to make the speculation a profitable one.

SELECTIONS.

MANURES: MORE ABOUT POTASH.

(Mr. M. Cochran in the Ceylon Times.)

IT may help towards a more intelligent use of artificial manures, if we examine the composition of Ceylon-made cattle manure. Two samples of this substance received from Mr. Joseph Fraser, of Damboolagalla Estate, Matale, had the following composition. No. 1 is the analysis of cattle manure from cattle fed upon cocoanut poonac and guinea grass, bedding being manna grass: No. 2 is the analysis of manures from cattle fed, upon guinea grass only, the bedding being manna grass.

	No. 1.	No. 2.
Moisture expelled at 212°	80·187	74·674
Organic matter and combined water ...	14·412	19 877
Ash	(5 071	(6·149
Insoluble silica	1·805	1 661
Soluble „	·209	·193
Oxide of iron, alumina, and phosphates ...	·563	·410
Lime	·497	·7 7
Magnesia	·067	·171
Potash	·951	1·068
Chloride of sodium and soda	·575	·827
Sulphuric Acid	·159	·2 7
Carbonic Acid and loss	·239	·863
	100·000	100·000
Nitrogen	·416	·611
Phosphoric Acid	·250	·192

The most striking feature in these analyses is the fact, that of the four chief manurial ingredients, *viz.*, nitrogen, phosphoric acid, lime, and potash, by far the most abundant is potash which averages fully 18 per cent. of the manure ash. The proportion of potash is much higher than in English farm yard manure, is indeed double as great. Analyses or the ashes of manna grass, guinea grass, and cocoanut poonac separately, would be desirable to ascertain the proportion of potash and other ingredients derived from each cf these sources. The percentage of potash in the manure from cattle fed on guinea grass only, is slightly higher than in the other, when calculated into the weight of the manure as it stands; but if calculated into the weight of the ash of the manure, it is slightly higher in that from cattle fed upon both poonac and guinea grass. The latter manure has a very decided advantage in respect of phosphoric acid. It was contrary to my expectation to find No. 2 richer in nitrogen than No. 1, and in the case of a substance so difficult to sample, from its want of hemogenity, as cattle manure, more analyses are desirable before accepting this as a general fact.

It was, however, to some extent confirmed by analysis of dung from cattle fed on guinea grass only (analysis No. 3) and that from cattle fed on cocoanut poonac as well (analyses No. 4).

	No. 3.	No. 4.
Moisture expelled at 212°	73·500	75·186
Organic matter and combined water ...	20·253	21·195
Ash	(6·247	(3·619
Insoluble silica	3 667	2·221
Soluble „	·828	·159
Oxide of iron, alumina, and phosphates ...	·499	·438
Lime	1·037	·464
Magnesia	·078	·086
Potash	·213	·091
Chloride of sodium and soda	·076	·043
Sulphuric acid	·112	·078
Carbonic acid and loss	·237	·039
	100·000	100·000
Nitrogen	·529	·392
Phosphoric Acid	·189	·174

Here again we notice that in the dung from cattle fed upon both cocoanut poonac and guinea grass, although the percentage of ash is much lower, yet the phosphoric acid is higher than in the guinea-grass-fed cattle dung. When guinea grass is the only feeding material, it would appear that both the dung and the manure are much richer in time than when cocoanut poonac is used as well.

From the large percentage of potash in Ceylon-made cattle manure, those holding different views regarding this substance will, most likely, draw opposite conclusions as regards its place in artificial manures. Thus the nitrogen and phosphate manurists will argue. that the very fact of cattle manure being richest in potash, shews that the soil from which it was derived, is best able to supply this ingredient, and there is therefore no occasion to add it in our artificial manures. The nitrogen, potash, and phosphate manurists, on the other hand, will argue that since potash is such a conspicuous ingredient of cattle manure (the stand by of the planter) it is wise to introduce a considerable proportion of it in manures for coffee of which it forms by far the most abundant mineral constituent. The balance of what little experimental data is as yet before us decidedly favours the latter view. We have the testimony of Mr. Graham Anderson and Mr. Tolpert, founded on actual experiments, in its favour, said experiments, moreover, having been carried out on soil richer in potash than those of Ceylon. In the March number of the *Journal of the Chemical Society* an extract from a leading Continental Scientific Magazine informs us that "experiments, which were carried on at Potsdam, shewed the most suitable manure, for fruit trees, to be a mixture of potash sulphate and supesposphate, which increased the number of blossoms considerably." Mr. Fraser also, I understand, has found that on Damboolagalla estate those fields at least, the analysis of which shewed a lower percentage of potash, responded very well to sombereorum, which is essentially a mixture of potash sulphate and superphosphate.

Of the commercial salts of potash, besides wood ashes, our choice for pecuniary reasons, is probably restricted, to the nitrate, muriate, and sulphate. The first can be had from India. A very good sample of nitre for agricultural purposes submitted to me by a Colombo firm, contained nearly 90 per cent. of salts of potassium, the nitrate constituting nearly 80 per cent. Much of the crude Indian nitre however is greatly inferior to this, containing much common salt, but if cheap enough useful as a manure. Nitre of 80 per cent. furnishes fully 11 per cent. of nitrogen, which thus constitute s it a highly nitrogenous as well as potassic manure.

Commercial muriate of potassium contains about 88 per cent. of muriate, and costs about £3 or less per ton. A crude muriate of potassium and magnesium called carnalite can be had from Strassfurt in Prussia for less than a third of the cost of the purer salt; but as it only contains 25 per cent. of muriate potassium, the purer salt would be cheaper. Kainit is a crude potash sulphate which comes from the same mines at Strassfurt. Voelcker's analysis of it is as follows:—

Moisture	3·36
Water of combination	10·88
Potassium sulphate	24·43
Calcium sulphate	2·78
Magnesium sulphate	13·22
Sodium chloride	30·35
Insoluble silicious matter	·71
	100·00

A cheaper source of sulphate of potash if still near its former price of £8 per ton is that made from kelp known as p'ate sulphate. The following are Dr. Richardson's analysis of the commercial salt made on samples taken from parcels of upwards of 100 tons.

	Irish.		Scotch.
Sulphate of Potash ...	77·43	75·28	83·06
Do. soda ...	22 31	20·80	14·89
Do. lime ...		·80	
Chloride of sodium ...	·76	·54	·67
Insoluble matter ...	trace	1·04	
Moisture	·59	1·55	1·44

Sulphate of potash has this advantage, for agricultural purposes, over the nitrate and muriate that it is less soluble in water.

The muriate dissolves in three parts of water at 60°, the nitrate in seven, and the sulphate in eleven. The sulphate moreover has been shown to have a certain amount of curative effect on diseased coffee A good deal more might be done by analysis, to ascertain whether or not, there is any correction between leaf-disease and a deficient supply of potash to the coffee plant. The coffee leaf, not being of direct commercial importance, little has been done, as yet, in determining the composition of the ash in the different stages of the leaf's growth. The tea leaf, on the other hand, has been analysed in all its stages, and it is remarkable the extent to which potash disappears from the leaf as it grows old. So much so, that Zoller affirmed "that the age of tea leaves may be determined from the analysis of the ash. Thus young leaves of which the best teas consist, contain much larger amounts of potash and phosphoric acid than the older leaves, which are comparatively deficient therein, while they become richer with age in lime and silica. The ash of a sample of young tea grown on the Himalayas amounted to 5·63 per cent., and it contained in 100 parts 39·22 of potash 4·24 lime, 4·33 oxide of iron, and 14·55 of phosphoric acid." (Hassall).

In marketable tea, the amount of potash in the tea ash, varies to a

great extent as the following examples from Watt's Dictionary of chemistry quoted by Hassall will shew, and where potash is low it will be observed soda is high.

	Souchong.	Souchong.	Oolong.

Phosphoric acid	16 64	17·44
Sulphuric acid	4 89	4·76
Silicic acid	10·89	5·59

Potash being the dominant element of the ash, of the coffee seed, the formation of fruit must tend to drain the leaves of their potash, and if the supply is not equal to the demand, we can imagine an abnormal condition of the leaf to be induced, rendering it liable to the attack of *hemeleia*, while the seeds would be reduced either in number or size. Again, if at any stage of its growth, the coffee leaf, like the tea leaf, requires a much larger proportion, of potash than at other stages, and the supply be not equal to the demand, we may in this case also have an abnormal condition of the leaf and disease as the result. I think at all events that this line of investigation is worthy of attention.

HOW OPIUM IS PRODUCED IN INDIA.

OWING to the ever poverty-stricken state of the Indian ryot, or husbandman, the Government advances the means whereby he can engage in poppy cultivation. The nature of their engagements is about as follows:—The cultivator undertakes to sow a beegah, or about one-twentieth of an acre, with poppy seed. For this he is given the requisite amount of seed. If a well has to be dug, he is not only given a sum on loan sufficient to carry out his purpose, but also money enough to buy bullocks, in order to enable him to draw water from the well when it is finished. This is termed the first advance, and is simply given to prepare his land for the sowing of poppy seed. The second advance is given when the plant begins to shoot above the earth's surface, and the third when the plant is about to mature. In January or February the plant comes to maturity; in that state the seed pods are lanced in the afternoon. The opium is allowed to exude till next morning, when it is carefully taken off by an iron scraper. At the same time precaution is exercised to close the incisions by running the finger over the cuts. About five to six incisions suffice for the drawing of the juice.

The opium is placed in brass vessels, slightly tilted, so as to drain off the dew or any other watery substance. It is then manipulated and placed in new earthen vessels, and is thus kept till it is brought to the weighing station. The cultivator of poppies does not employ labour. His holdings are mere garden patches; so all the aid he requires, from the sowing of the seed to the maturing of the plant and the gathering of the opium, can be had from the members of his family. The whole of this work is done by himself, his wife, and his little ones. Many of these opium garden plots, worked by the man and family, amount to only one-sixth or one-twelfth of an acre, perhaps: in a few isolated instances one man is wealthy enough to own half an acre.

There are many reasons which conduce to this. First and foremost is that the native does not like to lease more land than he himself can plough and work. Even with the growth of opium, where so many untold advantages are offered for extended enterprise, the Indian husbandman prefers to give his attention to a tiny garden, rather than to be put to the expense of working, with paid help, a few acres. His outlay is nothing, and thus he is enabled, at tremendous profit, to grow opium for sale to the Government. He does not pay for help; manure is always handy, as human excrement only is used, and nothing is cheaper and more effective. Irrigation is equally simple. A rude well is sunk; two posts and a cross-beam, over which is placed a wheel, form the only apparatus for the drawing of water. A rope is passed over the wheel, and attached to it is a huge leathern bucket, which is let down and drawn up by bullocks. The water is emptied into a reservoir; running from this are numerous drains, which carry off the water and flush the lands requiring moisture. The stronger members of the family are engaged in this toil, while the children, who in other lands would be deemed infants, make themselves generally useful in picking weeds and many other duties necessitating light labour.

Before the sun gilds the horizon, and while the dew is yet fresh on the grass, the family are astir, and from early morning till evening their entire attention is bestowed upon their crop, either in weeding, watering, or picking during the day; and sometimes at night, in keeping wild animals from intruding and destroying in a single hour the labour of years.

The wants of the husbandman are but few. Four mud walls and a thatched roof compose the family mansion; and in such a hovel will he live for generations. A scant cloth tied round his loins serves for coat and pantaloons. When he desires to appear to advantage, a huge cotton sheet, thrown in graceful folds around his body, serves as gala costume on occasions of great festivity. His little children are in a state of utter nudity, even in the coldest weather; and when it is borne in mind that from October till February the weather is a great deal colder than it is in San Francisco, some idea of the hardy nature of native children can be formed. The women are somewhat better clothed; a simple petticoat and a gray-coloured sheet has for the last three thousand years formed their attire. But whatever money the husbandman gains, he converts into jewelry, which forms the real wealth of the native landowner, and is regarded by natives much in the same way as a European looks upon a bank account. In times of acute distress he can always part, even at a permium, with his wife's ornaments. The Hindoo religion demands that certain ornaments must be worn by married women. When the contracting parties are poor, they make them of lead; but directly fortune smiles favourably, they are exchanged for gold and silver. The small farmer lives with but three objects, that is, to load his wife with ornaments, to eat off brass platters, and to be able, on the marriage of his son, to make a grand display. To attain this end, he will suffer years of deprivation and inconvenience, and his many years' savings will be wasted in a single week of jollification.

We can imagine how glad must be the ryot when the poppy plant has begun to exude opium, and when his opium has all been gathered he waits patiently for the order of march, with the fruits of his labour, to the weighing station. It depends entirely upon the season as to when the cultivators can bring their opium to the Government stations to be weighed.

As a general rule, the month of April is the commencement of the weighing season. Intimation is then given to the opium cultivators that they must present themselves on a certain day with their opium, in order to have it tested and weighed. In the districts where the poppy plant is cultivated all are astir, and grand preparations are made for a general exodus. The opium is collected safely in red earthen pots, which are put in wicker crates, and the whole family, with burdens on their heads, make for the weighing stations. The picturesque Indian lanes are crowded with these men, marching like sheep to their destination. They only travel during the night: the sultry heat of midday forces them to seek the grateful shelter of the gardens and groves so liberally planted along the dusty highways. Directly a halt is called, and preparations are made for the daily meal. After this is finished, some lively spirit starts a story, recounting the savage doings of the stranger who rules the land. With terrified countenances and anxious ears they listen to these fabulous tales; but inwardly they bless the "white face," as they think of the money he is soon to disburse.

Many of these ignorant cultivators have never seen in their life a European, and accept with easy credulity anything detrimental to the character of their governors. No wonder is it, then, that the native approaches the *sahib*, or gentleman, with the most abject fear painted on every limb. He holds his breath when he hears him speak, and is ready to faint at the slightest display of anger or impatience. These sensational stories are generally propagated by rascally natives, who profit by the credulity of their countrymen in order to extort money. These men represent that nothing can be done without the *bakshish* or blackmail present, and they are the agents for the *sahib*, sent by him to collect toll. If the ignorant wretch demurs, his torturer paints a picture to which the torments of hell are but a trifle. The poor fellow, anxious to escape such calamities as he is threatened with, pays the demand, and further presents his friend with a trifle in order that nothing should go wrong.

Early in the morning the weighing and testing commence. Notice is given to the cultivators, and they proceed to the factory, ranging themselves in a long line before the examining officer. Some men connected with the department then mix up the opium, and take out a small quantity for examination. The officer, after inspection, marks the quality on the side of the earthern basin in chalk. The samples are again mixed up and tested with a solution of tincture of iodine. If it happens that the cultivator has been attempting to adulterate his opium with farinaceous matter, the solution will discover the deceit. Experienced officers are alone trusted with this important duty, and it is expected of them to be able to distinguish the class of the opium as much by the feel and sight as by a chemical analysis. The consistency of the opium is easily told by a man who has been long at the work by simply turning the opium over with his hand, or with the aid of a knife. If the opium is of a first-class quality, the colour is a rich brown, and it is so stiff that there is some difficulty experienced in turning. The poorer the quality, the blacker the colour and the thinner the consistency.

After the opium has been weighed and filled in the separate jars according to its quality, they are sealed up and dispatched to the factory, where all the opium is again mixed up to a certain consistency and made into balls ready for exportation and sale at Calcutta. After the opium has once been delivered into the hands of the Government officer, the cultivator has nothing more to do. He is paid so much by the pound; his former advances are deducted, and the connection between the ryot and Government closes. When the balls are made, they are packed into boxes called "opium chests," and sent down to Calcutta.—*Journal of Applied Science.*

BEETROOT *vs.* CANE-SUGAR.

The perusal of M. Deleit's valuable paper on the sugar-cane, and the advantages to be derived from careful selection, has afforded me much satisfaction. It is generally admitted by experienced planters that in many instances the sugar-cane has deteriorated. This has been the result of a variety of causes, prominent among which are careless cultivation, unsuitable soil and climate, and want of care in the selection of plants. In other instances where a careful system of cultivation has been pursued and a judicious selection of plants made, the most successful results have ensured. This can be safely asserted from the results of an experience of many years in the experimental cane nursery established in connection with this department. That the establishment of experimental nurseries of this description in the whole of our sugar-producing colonies would be a source of benefit to all those engaged in this industry cannot be denied. Since the formation of this one in 1862, numerous applications for cane plants have been received, and many thousands of plants supplied; not only to the planters within the colony, but to others of Mauritius, Java, Honolulu, Figi, America, and other places, as far as the supply would admit of. They are furnished free of cost to the applicants, but there appears to be no reason why these experimental plantations should not be made self-supporting by adopting the Mauritius plan, where a small charge sufficient to cover the cost of production is made, and cheerfully paid by the planters.

At the present time we have seventy-eight varieties of sugar-cane under cultivation, no additions having been made during the past year. These varieties are now very generally distributed throughout the colony, and increased observations and experience confirms me in my previously expressed opinion, that soil and climate greatly affect the quality of the juice, and materially influence both in quantity and quality the sugar produced by the plant. This is shown by the fact that a variety of cane, strong, healthy, and yielding profitable returns in one district, when removed to another within fifty miles, has been known to lose many of its good qualities.

With regard to the selection of cane plants, the best developed and most vigorous plants should be chosen, as imperfect or diseased plants are not likely to produce good canes. The age of the plants from which the cuttings are selected is not of so much importance as favourable vigorous growth and well-formed joints and eyes. In the older sugar-producing countries the cane tops, most probably in the first instance from motives of economy, have been used for plants. Some growers prefer them, considering that they produce earlier plants than cuttings from the matured portion of the cane. It is very probable that this practice of planting the immature portions of the cane has been in some measure the cause of its deterioration; but whether the most sacchariferous joints of the cane produce the most profitable plants is, I think, an open question, for it must be borne in mind that the amount of saccharine matter contained in the sugar-cane does not remain the same throughout the year, at some periods the amount being hardly preceptible; but experience has not shown that cuttings taken when the cane is in this condition have produced worse plant canes than those taken when the density of the juice was at its highest. Something more than the saccharine matter contained in the cutting is necessary for the support of the young plant, for we find that upon planting a cane cutting, when the eyes shoot forth at the same time a number of roots are thrown out around the whole circle of each joint. Their uses are to supply the young plants with sustenance until they are sufficiently advanced to form their own roots. This sprouting of the eye and the simultaneous formation of roots, at the joint constitute the effort made by the cane to reproduce itself. If the cutting be deprived of these roots, the young shoots will continue growing for some time, and eventually die away before they have become strong enough to form roots of their own. From this we may safely infer that something more than sugar and gluten is necessary for the nourishment of the young plant in its earlier stages.

Whether the cane plant has lost its habit of seeding from the causes mentioned in your article of August 2, 1879, or whether even it ever possessed it, is in the absence of reliable evidence purely a matter of conjecture. As far as my knowledge of the plant extends, I am disposed to think that "cane seed" has not yet been found, although in Bruce's travels he mentions "that in the East cane may be raised from seed." This statement, however requires further confirmation, for although Porter repeats this upon Bruce's authority, subsequent investigations have not proved its existence. Numerous endeavours have been made to become possessed of it, but without success. The Royal Society of Jamaica took up the subject many years ago, and instituted a system of careful and comprehensive inquiry in order to settle this at that time doubtful point.

The result of the inquiry was "that no variety of sugar-cane was known to perfect its seed (or indeed to produce anything like seed) either in the West Indies, China, the Straits of Malacca, Egypt, or even in the South Sea Islands, as in all these countries the cane is entirely propagated by cuttings."

Numerous methods have been tried and many experiments made to induce the cane plant to perfect its seed, but hitherto they have proved unsuccessful. Attempts have also been made to get the flower of the guinea corn and Indian corn to impregnate and fructify those of the cane. The experiment succeeded as far as the growth of the plants, their flowering together, and the production of the seed upon the arrow of the Indian corn was concerned, but no seed appeared, and subsequent microscopic examination showed that no change had been effected as regarded the formation of the seed.

There is, therefore no well authenticated instance of the plant having been raised from seed, and Bruce's statement most probably was a mistake caused by his imperfect acquaintance with the language. This being the case, it would be beside our purpose to speculate upon the probability of inducing this plant to perfect fertile seeds, but rather to devote our attention to the varieties we already possess; and there can be no reasonable doubt that with judicious selection and careful cultivation very superior and fixed qualities may be obtained in the sugar-cane as freely as they have been in other plants.

That "sugar-cane has therefore rather deteriorated than improved, and it is only very recently that it has been perceived that unless some change can be introduced the cane will, by degrees, degenerate at the same time that the beet is progressively improving. The result would in time probably be the destruction of the great tropical sugar manufacturing industry," is, I venture to believe, not likely to become the case, for in this colony our sugar canes have improved through careful cultivation under suitable conditions, and this has also been the case in the Mauritius with many varieties of cane forwarded from here, as is shown by the fact that the Director of the Botanic Gardens mentions in his last report that the cane garden has been discontinued in consequence of the planters being fully supplied with new varieties. Admitting, as stated, "that the cost of carriage is greatly in favour of Europe, while the beet refuse is useful for cattle-feeding, and the root enables a good system of a succession of crops to be introduced on the continent, where this sugar industry vastly increases the production of meat and corn in the districts where it is commenced, in addition to giving very profitable employment in the agricultural season;" but on the other hand it must be admitted that the element of success in beetroot cultivation, upon which so much stress has been laid in the competition between sugar-cane and beetroot, is the value of the refuse material for cattle-feeding purposes. Even granting that the weight of the pulp is 18 per cent. of that of the beet, and the yield of pulp from an acre, of land is 72 cwts, large quantities of manures of various descriptions, and some of them costly ones, and only procurable with great difficulty at a distance from manufacturing centres, and in the case of sugar-growing countries at a cost that precludes their use, are required to preserve the fertility of the land; whereas in the case of sugar-cane, where the trash and megass is returned to the field and buried while in a green state, no further manuring is required. In this colony in no instance that I am aware of is the megass used for fuel, and many planters are now becoming aware of its value as a manurial agent in the preservation of the fertility to their lands, and are now using it for that purpose.

The success of the beetroot would be very problematical in this and most other sugar-growing countries as the 45th degree of latitude in the Northern hemisphere appears to be the southern limit of its successful cultivation in reference to the extraction of sugar.

The growth of plants in any country, supposing the description of soil to be favourable, depends—*1st*, on the temperature: *2nd*, on the amount of sunlight; 3rd, on the degree of moisture, and its presence at the time when most required by the plant. Climate is a great consideration to the growth of succulent plants, and, as a rule, an abundant supply of moisture is required; yet on soils too humid the beetroot grows large, but with much less sugar in it.

Another argument in favour of cane is its superior power of withstanding drought, which in the case of similar weather with a beet crop would result in a total loss. Our climate is as a rule too dry, and also too uncertain in the quantity of rain that falls, to allow of beet being ever generally adopted as a crop to supersede cane.

Another objection is that beetroot cannot be grown continuously upon the same land with profit, but must form one crop in a rotation. I have no data as to what the cost of working an acre of beetroot would amount to in this colony; nor has it yet been cultivated upon a sufficiently large scale to admit or even an approximate calculation. Beet cultivation was commenced, and a factory established some years since in the neighbouring colony of Victoria, but operations were suspended after the second season, the results not being sufficiently satisfactory; and the company has since been dissolved. In this instance the juice did not contain as great a quantity of saccharine matter, but contained a much larger precentage of saline impurities than the juice obtained in the beet-growing districts of Europe. No claim has yet been made upon the Victorian Government for any portion of a sum of £5,000 granted for "the encouragement of the manufacture of beetroot sugar grown within Victoria." This sum was to have been awarded at the rate of £10 per ton to the producers of fifty tons or more of beetroot sugar.

The area in which the culture of the beet has proved a commercial success appears to be circumscribed, as its cultivation and manufacture has been unsuccessfully attempted in England, Ireland, New Jersey, California, Canada, and Victoria.

Owing to the smaller quantity of saccharine matter in beetroot than in sugar-cane, and also owing to the more complex combinations in which it is found, it requires greater ingenuity and a more careful application of scientific principles in the extraction of the sugar. Putting on one side the question of profitable cultivation, this fact alone in cane-sugar producing countries would in most instances prevent its cultivation, for the producer would have to erect all the complicated and expensive

apparatus of a beetroot sugar refinery, in addition to that required for the extraction of the juice, and then to work the plant only during crop time—say for 100 days—and attempt to compete with European sugar refineries, which would be to enter upon a severe and unnatural competition which no probable yield would justify.

In fact the planter instead of an ordinary cane sugar producing plant will have established a sugar refinery, which working only quarter time will be so heavily, weighted that it must be hopelessly beaten in the race, and the profits from beet culture, if any, will be absorbed by the losses in refining. But in addition to this, a larger amount of both scientific and practical knowledge is necessary. The beetroot manufacturer must not only be a through practical agriculturist, but he must also be a good chemist, and familar with mechanics and engineering, in order to carry out improvements suggested by experience, and thus keep pace with the progress of other manufacturers.

The time may not be far distant when cane agriculture and manufacture will be conducted on more advanced principles than are usually applied at present: it is possible that the cheapness with which sugar can be made from cane will lead to the extension of its growth to such a degree that the price of sugar will fall to a point at which beetroot sugar manufacture ceases to be profitable.

From a careful consideration of the subject, I think we may safely arrive at the conclusion that in cane-producing countries the sugar-cane is not likely to be supplanted by the beetroot; and in cases where the cane plant has degenerated we must devote our attention to the discovery of the cause and its remedy, and not to the introduction of other sugar-producing plants.

That the degeneration of the cane plant does not proceed solely from the use of immature cuttings, we may infer from the fact that good results have been obtained from diseased canes when transferred to new country. From this we may reasonably infer that the exhaustion of the soil may have something to do in the matter. This exhaustion of the soil is the results of defective cultivation and insufficient manuring, and it is upon improved methods of culture and careful selection of plants more than upon new varieties of cane that the planter must mainly rely upon; at the same time there is no question, but that the introduction of new varieties of cane, and the adaptation of species to soil and climate, are important points in the general improvement of cane agriculture.

This article may well be concluded with the words of a West Indian planter of many years' experience:—"Modern improvements in agriculture have doubtless raised the yield of beetroot crops, and may do it still further; but in a similar degree is the agriculture of sugar plantations capable of further important improvements, and the yield of cane capable of being considerably increased.* So far as the production of sugar is concerned, the advantage is so greatly and obviously on the side of the sugar-cane that the decision against beetroot cultivation is arrived at as an *à priori* judgment, which has hitherto been held with considerable tenacity by the majority of the agriculturists in this country."—*Walter Hill, Director of the Botanic Garden, Brisbane Queensland, in Journal of Applied Science.*

SUGAR INDUSTRY IN QUEENSLAND.

FROM a report on this subject by Mr. Henry Ling Roth, it appears that the crops of sugar in this colony amounted in 1879, (that is 31st April 1879 to 31st March 1880) to about 18,200 tons, or about 4,500 tons above that of the previous year. The approximate output of the four sugar districts was:—

Southern district	... about 2,200 tons.
Central "	... " 5,750 "
Mackay "	... " 9,500 "
Cardwell "	... " 750 "

The output for 1880 is estimated at 21,000 tons, which is considered a low estimate. As far back as 1823, the late Mr. Thomas Scott grew the sugar-cane successfully under the patronage of Sir Thomas Brisbane, then Governor, and succeeded in obtaining 70 tons in 1827, at Port Macquire in New South Wales. This venture was carried out with the aid of convict labour placed at Mr. Scott's disposal by the Governor, but on the removal of Sir Thomas, the sugar establishment was broken up. Various attempts were subsequently made to establish the sugar industry without effect. Throughout Morton Bay previous to its separation in 1859 from New South Wales and its formation into Queensland, the sugar-cane was cultivated in the gardens of several people, so that there was little doubt as to the possiblity of its culture.

The first sugar known to have been produced in Queensland was made by Mr. Buhot, of Barbadoes, from cane grown in the Botanic Gardens, Brisbane, in May 1862. In 1868, Captain L. Hope had twenty acres under cane and the Society of Arts offered a medal for the first ton of sugar made in any of the colonies. By the end of 1867 there were 20,000 acres under cultivation for cane, and the six miles in existence manufactured 168 tons of sugar. At the close of the season of 1869 there were 28 mills at work crushing the cane from 1,280 acres, out of over 5,000 acres under cultivation. In 1875, the season turned out very bad, the cane, nearly drowned in wet, became unhealthy and died, giving next to no returns. In the course of time the evil effects of 1875 passed away, and the sugar industry has been since then, more or less of a success. The average yield of sugar per acre in Queensland, for the ten years ending 31st March 1879 (and including the rust year 1875,) is as follows:—

	cwt.	qrs.	lbs.
Southern district	24	0	25
Central "	24	2	9
Mackay "	27	0	23
Cardwell "	30	1	2
Queensland "	25	3	0

These figures may be compared with the yield of other countries, as in the following table:—

Country	Average yield per acre. lbs.
Demerara	4,480
Louisiana	1,200
Mauritius	3,500 to 5,500
Jamaica	1,344
Philippine Islands ...	2,800 (This has been stated as only 1,080 lbs.)
India	896
Rio Janeiro	2,100
Java	about 3,360

Mr. Roth writes respecting these figures:—"According to Porter, virgin land used to give 5,000lbs. of sugar per acre, and Edwards in his 'History of the West Indies,' speaks of soil in Jamaica, which with plant cane will produce 2½ tons (5,600lbs.) of sugar to the acre. Now, in Queensland, 3½ tons and over, or above 7,840 lbs. per acre, have occasionally been obtained from soils newly broken up, but such a yield is exceptional." The manufacture of rum has increased at the same rate as that of sugar. The total production since 1867 was 1,842,322 proof gallons. Up to 1876, the yield was at the rate of over 2 gallons of molasses fermented to 1 proof gallon of rum distilled. For 1877, it was at the rate of 1-4/3 to 1, and in 1878, at the rate of 2 to 1.

The mean consumption of sugar in Australasia is greater than in any other part of the world. The consumption of sugar and molasses in England for 1878 was at the rate of 62½ lbs. per head. Australasia, however, consumed 78·71bs. per head, or 16 lbs. per head more than England did. Of the colonies, Queensland is the greatest, and South Australia the smallest consumer, their consumption being 92·13 and 71·31lbs. respectively. Australia draws her supplies from various quarters. Of the 91,500 tons which went into consumption in 1878, one-sixth was produced by Queensland, and one-twelfth by New South Wales, thus one-fourth of the sugar consumed in Australasia is produced in Australia itself. The remaining three-fourths are imported chiefly from Java and the Mauritius, supplemented by small supplies from the minor sugar-producing countries.—*Journal of the Society of Arts.*

ARUNDINA BAMBUSŒFOLIA.

ALTHOUGH neither the hills nor plains of India can boast of the more gorgeous species of Lilium—(those magnificent ground orchids that are furnished by Mexico and South America)—there are several that will be even perferred to them by many from their greater delicacy of bloom, and the first place must be given to the really handsome flower whose name stands at the head of this paper. As far as my experience goes I do not believe that either of the three varieties are found in any other place but the Khasia and Garrow hills, although there is no reason why it should not be indigenous to many parts of the Himalayas, round about Katmandu especially, and even Darjeeling. On its first introduction to England, it attracted universal attention, but has since fallen out of favor (or fashion), In fact, like many of the East Indian orchids, it has been sent home in such quantities as to become rather a drug in the horticultural market. Another reason for its present disfavor is, that people at home do not know how to treat it, and this remark is applicable to most of the Indian varieties. Many orchid fanciers are at length awaking to the fact that their gardeners are unable to comprehend that Indian orchids comprise both hot and cool varieties, and are insisting on treatment more in accordance with the natural habits of the plants entrusted to their care that has been the case hitherto. The orchid fancier in India possesses immense advantage over his European compeer, for he gets his plants fresh at a nominal cost, and if unacquainted with their proper treatment, can obtain all necessary information within a day or two. To return to the *Arundina*. The first variety grows to an average height of four feet, having stout red-like cane stems as thick at the base as a man's index finger, tapering gracefully upward till it ends in the flower spike about six inches in length, bearing usually from eight to ten buds about an inch apart. The sepals and petals are in this variety rose-colored; the lip paler, but beautifully splashed towards the edge with

* This has already been done, as I find that under date February 5, 1877, Mr. J. F. V. Minchin, of Aska, writing to the Editor of the *Indian Agriculturist*, says, speaking of the diffusion process, "By this process I extract 67½ per cent. of the 90 per cent. juice the cane contains. I send you by dak a sample of sugar turning out to-day." The editor adds: "The sugar is granular, and of good quality."

crimson spots or blotches, with a pale canary bloom towards the base. This large Arundini is seldom found above 1,300 feet, and not very frequently lower down, although my experience is not to be taken as a hard and fast rule. The plant requires leaf mould, sand, and a small proportion of crushed limestone. In Calcutta the best means of growing this (which, for the sake of reference, may be called *A. majus*). would be in shallow pots with about four inches of soil upon a layer of corks or lumps, or broken brick. Subject as the plant is to a rainfall of some 300 inches, it will require copious watering in addition to what it will get during the rains in any part of Lower Bengal, and during the hot weather it must be kept in a cool shady part of the verandah, allowing just sufficient water to keep the soil moist. As soon, however, as the rains regularly set in, the pots should be put out in the open, so that they can get all the light and air possible. The plants will flower all through the rains, and as a rule, up to Xmas, if kept free from dust; then comes a period of rest till about the middle of April, when they should be taken up, the new bulbs and stems separated, and all reported in fresh mould. The flowers usually unfold themselves in couples, but in one very robust plant that the writer manured, four and five came out at times. They last usually four days, and may be nipped off as they begin to fade, unless the seed is required. Removing the drooping blossom tends to open out the new buds, and by a little attention to this a continuance of pairs of these beautiful flowers may be had daily for six months of the year. For transport from the hills all that is necessary is to pull up the plant, knocking off he superfluous mould, and wraping some moss round the roots. It is quite unnecessary to cut down the stems, as many people do, for the plant will not only travel much better with them intact, but if potted and washed on arrival, the leaves rapidly recover from the effects of the journey; and, though blossoms need not be looked for until the rains, the plant is an attractive object even without them, far more so than an unsightly leafless stick.

In and about the same locality, but in more shady places than those in which *A. majus* delights, is found a diminutive species, that to an amateur would present the appearance of being a young shoot of the former, but it differs both in foliage and blossom. The bulb is about the size of an ordinary spring onion, the stem, which is but six inches in length, and is succulent and almost leafless. This may well be called *A. minor*. The flowers seldom develope more than one at a time, and are small, of much less delicate hue than *A. majus*, and the lip is almost a uniform colour with the rest of the flowers, but is longitudinally striped with scarlet, the canary bloom in the other variety being represented by a deeper though less brilliant shape. This is not a desirable plant, although improvement might possibly be effected by hybridising with the pollen of some of the white orchids, such as *D. formosum*, or still better *Plisone maculata*. No plant that I am acquainted with would be benefited by being hybridised with the pollen of *A. minor*; with the exception of required shade the cultivation of this plant is the same as the one alluded to above.

In addition to the two plants just treated of, there is another *Arundina* with a flower precisely similar to that of *A. majus*, but borne on a slender whip-like spike about a foot in length from where the leaves terminate. The whole plant seldom attains two feet, and when not in flower is, from the resemblance it bears to the numerous grasses around, most difficult to distinguish. Considering that the flower is in all respects like the large variety, I am inclined to conclude that the dwarfed proportion of the plant is due to the greater elevation and more exposed parts of the country which it inhabits. In the month of August the whole country (from the top of the precipitious face of the hills, abutting on the southern plain, from 1,500 up to 4,000 feet or, to put in more intelligibly, say from the 21st mile stone on the Jaintiapore road till one reaches the quartz formation about five miles from Jawai is covered with those beautiful lily-like flowers interspersed with some white and yellow *Calanthi* and numerous other flowers as yet unclassified. During this month the rain is almost incessant, and penetrates to the skin, driven, as it is almost horizontal, the tremendous downpour would rot the bulb of almost any plant were it not for the natural drainage, and the *Calanthi* alluded to are found in places so very like swamps that a cursory observer would, at a first glance, be inclined to classify them as semi-aquatics. The bulbs of the *Arundina* retain moisture sufficient, out of this abundance, enabling them to go on flowering for months after the cessation of this deluge; and, though the plant may be said to have its home within the rainbelt, I have come across isolated plants nearly 6,000 feet above the sea; and when found at this elevation, I invariably noticed that, though the flower is of the usual size, the whole plant does not exceed four inches in height, so that, for presents for friends in Europe, they would be admirably suited. In packing for the trip home, it is simply necessary to lay the entire plants in an oblong box, and as a hundred will go in a case, four feet by two by two, there ought to be little difficulty in getting a large proportion home in good condition.

ALTHOUGH *Thunia alba* does not come in due alphabetical order, still as it is a ground orchid, it may as well be placed here. This plant is found in perfection in the vicinity of the numberless streamlets that come tumbling down the hill side during the rainy months; and, though in most cases it flowers before the actual rains set in, it is readily found, as the peculiar shape render it conspicuous even amidst the tangled mass of vegetation it delights in, springing from a small bulb; the pale green stem jointed at intervals of an inch or so, grows to a length of about eighteen inches, although in favourable localities plants are occasionally met with double that size. The leaves are long and lance-like, projecting from the joints, and the flower resembles a white lily when fully developed, about three inches across, but from the slenderness of the stem, it is seldom the flower is found, except in a drooping position, and so is hardly ever seen developed in its native state. The lip is striped, longitudinally, with vermilion. This is an instance among plants that proves that improvements in Nature can be made, for when taken from the moist steamy ravine and potted in crooks with but the least possible amount of moss and dead leaves, the drooping stem kept in an upright position by a stick, *Thunia alba* shew to great advantage; the leaves become broader, and the whole plant assumes a much more robust appearance than any one looking at a freshly imported one from the jungles would believe possible; the flower opens out thoroughly. As noted above, a very small amount of soil—if soil it can be called—is required for this plant, which, in its own home, is found adhering to the fibres of washed-out moss and leaves matted together by the action of water. Cocoanut fibre is suitable, if it has all the smell thoroughly washed out of it, but if used fresh, it undoubtedly possesses some ingredient detrimental to most orchids, extensively used though it be. Although the plant will grow well under the shade of a tree, it will thrive better in pots, for during the hot weather it should be kept in the coolest place in the verandah, and where water is available, a spray should be kept playing during the day imitating, as far as can be artificially done, the mist that it receives in its native ravines. All orchids, even ephytical *Dendrobiums* should, I am of opinion, be grown in pots, baskets, or on blocks of wood in preference to being established *in situ* on trees in the compounds (where they can only be seen by daylight, while, if grown as suggested, they can always be moved and rendered available for decorative purposes, either in the house of the proprietor or hired out for special occasions, while, when the time comes for returning home, the small quantity of established orchids one can collect about them will take up but a small space for freight, cost little, and if not required by the owner in England may be sent to a nurseryman until the ill-effects of the voyage are remedied; when, at auction, they should realize enough to pay one's passage; but it is as well to mention here that, what are called in England "imported orchids" those just fresh from the ship hardly pay their freight in the present day, for this reason, that the great fanciers at home do not care for the trouble of recovering them from the journey, and also run considerable risk in buying them in their dormant state of getting varieties other than what they believe they bid for. Hence, so far as freshly arrived plants are concerned, the trade is entirely in the hands of the dealers, who apparently, to judge by recent sales, have some understanding among themselves by which they control the auctions.

OSWIN WEYNTON.

AUSTRALIAN WINES AT THE EXHIBITION.

AFTER reading over the published list of awards made by the wine jury, some of our wine-growers may have experienced a feeling of disappointment that none of the Australian wines had attained to the highest honour, a first-class order of merit. Such a feeling, to those engaged in the wine producing industry and desirous of promoting it, is very natural, and has our warmest sympathy. A knowledge of the conditions under which the awards were made, and a little reflection on the very high standard of excellence, it was necessary to reach in order to secure a first award, will, we feel confident, dispel the feeling of disappointment, and cause a feeling of intense satisfaction to take its place. True it may be said "Australian wines received first awards at the Paris Exhibition in 1878, where they were judged by thoroughly competent jurors, how comes it that they are now beaten on their own grounds?" The answer is, here they were judged upon quite a different standard. The first awards at Paris simply meant the best quality of Victorian, New South Wales, or South Australian wines respectively. Those prizes did not even carry the weight of prizes gained at an intercolonial exhibition of wines. At Paris the wines of the various colonies did not compete with each other nor with the wines of the old world. The wines of each colony were judged by themselves. Victorian competed with Victorian, South Australian with South Australian, and German with German. Thus it will be seen that the award made at the Paris Exhibition differed but little from the awards made in the various colonies when the wines were selected except inasmuch as those awards were made by a foreign, and it may be assumed, a more competent jury. The principle on which the judging has been carried out at the Melbourne Exhibition is altogether different. Wines, as well as all other exhibits, have been judged by an international standard. Hence our Australian wines had to compete with the choicest vintages of France and Germany—in fact of the whole world. Under these circumstances it was scarcely to be expected that our vignerons would be able to take up a place in the front rank. It is no small honour—an honour vastly superior to the first awards gained at Paris or elsewhere—that Australian wines on their merits should be found ranking with the best brands of Austria, Italy, and the great majority of French and German wines. In the old world, generations of experience have enabled the vigneron to select the variety of vine best adapted to the soil and climate in different districts and different countries. The most suitable vines have been planted in quantity. In the after-treatment of wines, continental wine merchants possess an accumulated store of knowledge, the result of long experience. Both as regards the best and most suitable varieties of the grape vine for different districts, and also in the after management of wine in this climate, it is no disparagement to say that our

vignerons are as yet merely experimenting. Those who know most are readiest to admit that they have yet much to learn. Considering the youth of our wine industry, and the conditions under which it has been so far developed, there is every reason to feel proud and satisfied with the position occupied by Australian wines at the Melbourne International Exhibition.

PAPER MANUFACTURE IN FOOCHOW.

A COMPARISON of the manufacture of paper in China with that of foreign countries shows a wide difference. While in foreign countries paper is made by machinery from cotton and linen rags, hemp and straw, it is made by hand in China from the shoots of bamboo (not the edible ones) and upon illustrating the process of manufacture it will be found to be quite simple.

The bamboo trees usually produce shoots as soon as spring commences *i. e.*, in the 3rd moon (April to May) when the owner of the groves of bamboos proceeds to collect the full grown and tall shoots which are leafless. After being gathered, these shoots are each split into four parts or slices and are placed in an empty cistern underground formed by planks so as to prevent the water which is placed therein from afterwards leaking. The cut shoots are placed in the cistern together with unslackened lime or *chunam* in alternate layers. Water is then introduced and the cistern filled; the immersed shoots remain in the pool for forty days, at the expiration of that time, the lime water is withdrawn, and clear unadulterated water is placed therein and allowed to remain for fifty days. When this latter period has elapsed, the bamboo shoots are removed to a large circular stone vat without water, and a buffalo is then employed for the purpose of trampling the entire mass into pulp. After being sufficiently reduced, the pulp is removed to a sort of wooden trough, called by the Chinese a Chih-tsao, measuring about 8 feet (*Chihs*) long by 4 broad, and clean water again is introduced. After becoming properly decomposed, the coarse pulp is removed from the wooden trough with an iron scoop strainer and the fine decomposed dust remains in the water. A sort of grass called "Lan Tsao" previously well soaked in water, is then added to the pulp, and the entire mass is then stirred up with a bamboo broom. The pulp is now ready for being made into sheets of paper. A man with a square sieve dips the same into the trough and a sheet of paper is formed thereon, which is handed to another workman ready to receive it. The wet sheets are then taken to the fire or drying house, where poles placed obliquely, in tent-like form, about 15 feet apart at their base are ready to receive them; and upon each side of which 30 sheets of the wet paper are spread, whilst underneath the tent of paper if we may use the term, a pan of charcoal fire is kept constantly burning, in order to rapidly dry the sheets of paper. While a special kind of bamboo shoot can only produce paper, its manufacture greatly depends upon the various manipulations of the workmen employed. All kinds of Chinese paper are dried in the manner as described above, except the qualities used for umbrellas and the coarse kinds, which are dried in the sun. The coarse refuse of the paper pulp is sent to the various seaboard cities and towns to be used as oakum for caulking purposes. There are two small paper manufactories lying some distance back of Po-Ney-Shan, but these are principally engaged in *coloring* paper.

There is no province in China which can compete with Fohkien in its paper manufacture, and after tea and poles, paper by far is the largest item of export.—*Foochow Herald.*

MAURITIUS.

VANILLA; this bean has been the object of a brisk demand since the receipt of the mail, the advices to hand by which of a further advance in prices having rendered speculators in this market most eager to make purchases. Failing a sufficient stock of matured vanilla to meet the demand of our buyers, recourse has been had to 'time bargains' for green vanilla, to be delivered during the ensuing season and prices for the bean in this state have ruled from about Rs. 2·50 to Rs. 3 or even Rs. 3 50 per half kilog. The earliest purchasers in the field were able to enter into engagement for a certain quantity at the first named figure, but the growers have become less anxious to sell, and will not now quit their next crops on easier terms than Rs. 3 to Rs. 3·50, according to length of bean.

Matured and well prepared vanilla is in many cases held for Rs. 18 to Rs. 20 per half kilog, though we should mention that some indifferent parcels have changed hands at lower figures.

The preparation of last yield is now concluded, but it is an extremely difficult matter to arrive at an exact estimate of the quantity of vanilla made, which can only be determined in a reliable manner on its exportation. We shall not be very wide of the mark in estimating last yield at 18,000 kilogs, or perhaps even a little over.

The exportation of vanilla pods, per the mail steamer *Dupleix* is stated to be as follows:—

For England, 5 cases weighing 200 kilos.

For France, 44 cases weighing 1,446 kilos, 250 grammes.

CULTIVATION OF VANILLA.

THE high price of vanilla should encourage the cultivation of this plant in many of our colonies, which are well adapted to its growth—*e.g.*, Ceylon, Queensland, New South Wales, the West Indies, British Guiana and Hondura, Fiji, and parts of New Zealand. Some portions of South Africa and many districts in India would no doubt, also prove capable of yielding an abundant supply of excellent vanilla. Mauritius is at present our only colony where the culture of this plant is systematically carried on, though small experiments have been made, with encouraging results, in Jamaica.

As it requires special treatment, a few remarks upon its cultivation may be of interest to those who may be tempted to make the experiment.

In Mexico, vanilla is planted either in a forest or in a field. In the former case the underbrush, climbers, and large trees are cut down and removed, and young saplings only preserved to serve as supports to the vanilla plant, preference being given to trees having a milky sap; near each tree two cuttings of the vanilla plant are placed side by side in a shallow trench 1½ inch deep, and sixteen inches long, three knots of the stem being laid in this trench and covered with dead leaves, brush, &c. The rest of the cutting to the extent of three or four feet is placed against the tree and tied to it. The supporting trees should not be nearer than twelve or fifteen feet apart, to give sufficient room for the development of the plant. After a month the cutting will have taken root and must be carefully kept free from weeds and briars of all kinds. In the third year the plant begins to bear fruit which it continues to yield for many years.

When the vanilla is cultivated in a field, the Mexicans first plough the ground thoroughly, and raise on it a crop of maize. In the protection afforded by this plant, a number of young milk-bearing trees of the fig family grow, which in about a twelve or eighteen months are large enough to answer the purpose of supports to the vanilla plants, which are then placed as above described. In Mexico and Guiana the plant is allowed to climb up the trees, the fertilisation of the flowers is left to Nature, and a large number of flowers consequently remain unfertilised, and the yield of vanilla is small. In a few days after fecundation the flower falls off and the fruit continues to grow till the end of the first month, it takes, however, another five months before it is completely ripe. Each pod must be gathered separate and not the whole cluster at once, the time to gather them being indicated by the pod cracking when pressed with the fingers. If too ripe the pods split in drying, changing in colour from yellow to brown and black. If not ripe enough the fruit will lack fragrancy and proper colour. The ripe fruit has no odour. At first the agreeable odour of vanilla being developed by a process of curing. While the fruit is drying, an unctuous dark red liquid, called balsam of vanilla exudes.

In Mexico the pods are collected and placed in heaps in a shed to protect them from rain and sunshine, and left there for a few days; they are then, if the weather is warm and clear, spread early in the morning on a woollen blanket and exposed to the direct rays of the sun; at about mid-day the blanket is folded round the beans, and the bundle left in the sun for the remainder of the day. In the evening it is enclosed in tight boxes to "sweat" all the night. The next day the same treatment is adopted, and the beans, after exposure to the sun, acquire a dark coffee colour, the shade being deeper in proportion to the success of the "sweating" operation.

If the weather is cloudy, the vanilla is collected into bundles, a number of which are packed together into a small bale, which is first wrapped with a woollen cloth, then with banana leaves, and finally with a stout matting, which is firmly bound and sprinkled with water. An oven is then heated to 144° F. (60° C.), and the bales containing the larger beans are placed in it. When the temperature has fallen to 113° F. (45° C.) the smaller beans are introduced and the oven closed tightly. Twenty-four hours afterwards the smaller beans are taken out, and twelve hours later the larger ones. The vanilla has then acquired a fine maroon colour.

The drying operation then commences. The beans are spread on matting and exposed to the sun every day for about two months. When the drying is nearly complete, it is finished in the shade in a dry place, and the pods are then tied up in small bundles for sale.

In the Island of Reunion a different method is adopted.

In the first place the vanilla plant is never allowed to grow out of human reach, the different trees on which it is supported being connected by pieces of bamboo or other wood, placed horizontally, so as to form a kind of lattice, on which the vanilla can spread freely. As the vanilla loves a moist soil, and will not bear a burning sun the trees are never cut down. If grown in a field the support chosen is usually the physic nut *Jatropha cureas*, on account of its rapid growth and abundant milky juice.*

When the trees are of sufficient size to shelter the plant, the cuttings are set between the trees in a trench, eight inches deep, and covered with dry leaves, straw, and a little soil. This is generally done in the rainy season, as the cutting requires frequent watering while it is taking root. The shoots are trained on the lattices when they have begun to grow freely, and in two years are in full bearing. A length of stem of twelve to twenty-six inches in a state of Nature, although it may produce more than forty flowers, rarely yields more than one pod—the flowers being only capable of fertilisation by the aid of insects.

A man named Edmund Albins, a former slave in Reunion, discovered that if the pollen of one flower was made by artificial means to fertilise the stigma of another flower, it was possible to obtain more than 3,500 pods from a single plant, although this would cause the death of the plant before they could ripen. The method adopted, therefore, is to choose on each cluster the finest flowers, and only fertilise three

* How far the irritating property of vanilla which is sometimes manifested in vanilla ices, &c., may be due to the growth of vanilla on an acid euphorbiaceous plant may be worthy of inquiry. The use of fig-trees, as in Mexico, would seem at all events to be safer and more judicious.

presenting a large and fleshy peduncle. These are known to be successfully fecundated, if the flower, instead of dropping off, remains and dries on the top of the fruit. When this is observed, the rest of the flowers are cut off.

When ripe, the pods are sorted according to length, and scalded. The long ones are dipped into water at 194° F. (90° C.) during ten seconds, the medium ones fifteen seconds, and the shorter ones, one minute or longer. They are then exposed to the sun between woollen blankets until they acquire the characteristic maroon colour, which occurs in about six or eight days. The pods are then spread on hurdles, and placed in garrets to dry gradually. As in this colony the roofs are flat, and covered with tin, the garrets are in reality drying closets with a stream of warm air continually circulating through them. When the drying has proceeded so far as to allow the pod to be twisted easily round the finger, the operation called "smoothing" begins; and this requires great care, as every bean must be passed through the fingers from time to time, so as to spread the oil which exudes on the whole length of the bean, as the fermentation proceeds, for the lustre and suppleness of the vanilla depend upon this treatment. The beans are also turned frequently, so as to ensure their drying equally on both sides. In a month the pods are dry and are then sorted according to their length, and into the three following varieties: *1st.*—Fine vanilla, from eight to eleven inches long, glossy, dark brown, and unctuous, and soon covered with minute, frost-like crystals, technically known as *givre*. *2nd.*—Woody vanilla, from six to eight inches long, lighter in colour, not glossy, presenting grey spots on their surface and having very little *givre*. These generally come from pods not quite ripe. *3rd.*—Vanillon, consisting of two varieties, both of which are short. The best are obtained from ripe fruit and are covered with white crystalline efflorescence; the inferior are obtained from abortive or unripe fruits, and owe any odour they possess to having been in contact with those of better quality.

A slightly different method of drying is adopted in other vanilla-growing countries. In Guiana the pods are placed in ashes and left there till they begin to shrivel. They are then wiped, rubbed with olive oil, tied at their lower end, and hung up to dry in the open air. In Peru the vanilla is dipped into boiling water tied at the end, and hung in the open air; after twenty days the pods are rubbed over with castor oil, and a few days later are pressed into bunches.—*Colonies and India.*

WHY WE USE QUICK LIME UPON THE LAND.

ALL cultivated plants contain lime in their ashes, and it is considered necessary to their proper growth. But as soils generally contain enough lime, and we apply it for its action upon the soil, lime acts upon it and greatly aids the decomposition of organic matter in the soil. It is thought to neutralize the organic acids contained in what are called 'sour-soils.' In a complicated manner it aids in the fixing of ammonia. It also acts upon the inorganic or mineral constituents of the soil, and aids in converting them into forms in which they can be taken up by the plants, especially in liberating potash from its combinations. The effect of lime upon the mechanical condition of the soil is an important feature. Upon heavy clay soils its effect is most marked: the particles lose their adhesiveness, and allow air and water to enter. These are the leading effects that follow the use of lime. In view of the claims made for ground, unburned limestone, it is an important question how far it can produce the above effects. That the unburned limestone will supply the demands of the plant for lime, that it may slowly neutralize organic acids, and help the mechanical texture of the soil, seems very probable. But that it will perform one of the most important offices, the decomposition of organic matter in the soil, and convert that into plant food, seems improbable, because the ability of lime to do this depends in a great measure upon its avidity for carbonic acid, while limestone, being already a carbonate, has no need of more. That limestone cannot produce all the effects of lime is shown by the well-known fact that soils underlaid by limestone, and naturally containing a large proportion of finely divided carbonate of lime, are as much benefited by the use of quicklime as are soils deficient in limestone. The advertisements of ground limestone that we have seen, make great use of the experiments of one person in Pennsylvania, who states that his yield of wheat, created with ground limestone, was more than double that to which slaked lime has been applied. He also claims to have found it a much cheaper fertiliser than lime and bone dust, and more profitable than guano and superphosphate. These statements have been sent by several who ask our opinion. Our 'opinion' is that we do not accept as final the results of any one experimenter, when they are in direct opposition to the accumulated evidence of those whose practice runs through many years. In nothing more easily than in agricultural experiments can an effect be ascribed to the wrong cause, and when we see the fertilising value of ground limestone placed above guano or superphosphate, we do not accept it.—*American Agriculturist.*

HEMP CULTIVATION IN MEXICO.

THE hemp industry in Mexico has, within the last ten or twelve years, attained considerable proportions, and one of the chief articles of trade in Yucatan, is the fibre extracted from the hemp plant, or American aloe, commonly called by the Indian name of "henequen." Consul Laspinasse states that the plant is found in profusion throughout Yucatan, and forms the nucleus whence all the present hemp plantations have been formed. The hemp tracks are divided into "mecates," which is a Mexican measure of 24 yards square. After all the shrubs and weeds have been burned during the previous dry season, the Indian labourers proceed to dig small pits, in a straight line, from six to eight feet apart, and between each line of pits, a path about nine feet wide is left clear, in order to give the labourers sufficient room to cut the leaves when they have attained their full growth. As soon as the required quantity of land is thus laid out, the young plants are cut close to the ground, and, without any further process, are simply placed in the pits prepared for them, with a little loose earth, and are left to take care of themselves. Each "mecate" contains about 96 plants. Twice a year the ground is cleared of the underwood. As the plants grow, a stem shoots out from the centre, and the leaves gradually detach themselves from it in a spear-like form, with sharp prickles along the edges, and a strong, black, sharp needle-like thorn at the point. The plant requires from five to seven years to attain its full growth. At the end of this period, the leaves have an average length of four feet. A hemp plant will flourish from 10 to 15 years. Each plant has about 26 leaves during the year, 16 in the rainy season, and 10 in the dry; each leaf, four feet long, produces about three-quarters of an ounce of fibre; it requires, therefore, from seven to eight thousand leaves to make a bale, weighing four hundred pounds. As soon as the plant has attained its full growth, the leaves are cut from the trunk, commencing from the bottom upwards, only those being cut which are well developed. From the hemp beds they are carried to the scraping-machine, which consists of a strong fly-wheel, on which six or eight blunt brass knives are placed transversely. The leaves are placed one by one on a curved lever, which is raised or lowered in such a manner that the knives on the wheel only strike the pulp and lay bare the fibre. First, one end of the leaf is presented to the wheel, and as soon as it is scraped the other end is presented. Each time one end is introduced, the other is secured by a strong pair of iron pliers, which are attached to the machine. Each machine employs four men, one to place the leaves near the machine, one to attend the lever, one to introduce the leaves into the machine, and the fourth to carry away the pulp and refuse matter. As a rule, the machines are worked by steam-power, and can clean about four hundred pounds of fibre in one day. When the fibre is extracted from the leaf, it is taken to the drying-yard and hung on slender poles, which are stretched on wooden frames about three feet from the ground, and left to dry and bleach in the sun. If the weather is fine, it will become dry in four to five hours. While drying, the fibre loses its natural greenish hue and assumes a white, glossy appearance. It is then placed in hydraulic presses, and compressed into bales of the required size, which generally weigh three hundred and fifty, four hundred, and five hundred pounds. The fibre is then ready for shipment.—*Society of Arts Journal.*

DEEP PLOUGHING.

THOUGH experience at home has for many years proved the advantage of deep ploughing for all descriptions of crops, and in all sorts of soils, amongst the conservative agriculturists of India there have been, up to the present, a majority who have always argued that it was unsuitable to this climate, where the scorching sun would soon exhaust all the moisture from the too deeply loosened surface soil. Especially, they argued, would this be the case with rice and other plants, the roots of which penetrate but little below the surface. It is, therefore, a most important matter for all engaged in the cultivation of the soil in this country to learn the results of some experiments in deep ploughing, conducted last year at the experimental farm at Cawnpore, by Mr. Fuller, the Assistant Director of Agriculture in the North-West Provinces. The results obtained are all the more satisfactory for the supporters of deep ploughing, as the season was an unfavourable one. We are told that the failure of the autumn rains greatly interfered with the success of the experiments, especially in the case of those conducted to test the value of manures. "The rainfall, as measured on the farm between 1st June and 30th November 1880, only amounted to 6·06 inches (the normal for that period being about 27·6 inches), and was actually less by 3·07 inches than the rainfall during the corresponding month of 1877, the year of scarcity. As regards its *distribution*, however, the season differed broadly from the corresponding period of 1877, firstly, in that the rainfall was spread over more than double the number of days; and secondly, in that the month of maximum rainfall, was July instead of August, and the young plants received a start which enabled them to withstand, in some measure, the drought of subsequent months instead of as in 1877, being starved at the very commencement of their growth. A large number of the experimental fields were irrigated from the Ganges Canal, and fair crops gathered in consequence. But irrigation could not in many cases be given at the time it was required, since the farm lands depend for their water-supply on the tail of a distributary, and received it very irregularly. Maize suffered most conspicuously, and unfortunately this was the crop with which most of the experiments on manures were made. The manures experimented with were unable to produce their full effect in the absence of sufficient water, and the results which were obtained must be held unreliable.

But the failure of rain was not without service in another direction, since it brought out with extraordinary prominence the great benefit which results from a deeper cultivation of the soil than that generally in vogue. Experiments to test the value of deep cultivation with and without inversion of the soil, were tried with representatives of deep feeding and shallow feeding crops, *i.e.*, those which penetrate deeply into the ground by a tap root (*e.g.*, cotton and the pulses) and those which feed nearer the surface by a "crown" of fibrous rootlets (*e.g.*, maize, millets, and all other cereal grasses). The results have shown that it is the former class of crops which benefit most strikingly by an increase in the depth of their seed bed, while in the case of the latter class of crops the disadvantage resulting from the rawness of the fresh soil brought to the surface may, at the outset, more than counterbalance the advantage

they derive from the greater depth of tilth. This accounts for the numerous instances reported from Court of Wards Estates and elsewhere, in which the use of the English plough actually diminished the outturn since the experiment was invariably made with a cereal, and the results were judged from the crop gathered in "the first season after the ploughing before the newly turned soil had had time to mature. The results of the experiments of the season under report appear to leave no doubt that tap-rooted plants derive an immediate and striking benefit from a deeper seed bed than that which is generally prepared for them. Details of these results are given in para. eight of the report, but it may be noted here that in one case cultivation with the English plough gave, on *unirrigated land*, an outturn of 860lbs. of cleaned cotton to the acre, while the ordinary cultivation of the country only yielded 150lbs., which was, if anything, above the average outturn for the unirrigated cultivated fields in the neighbourhood of the farm. *The use of the English plough, therefore increased the value of outturn by Rs. 4 per acre.*"

The result, therefore, may be said to be that those plants naturally benefit most which are deep feeders, and by means of a tap-root utilise a larger food-supply if made available by a deep stirring of the soil. Thus cotton benefited in a remarkable degree by deep cultivation, both with or without inversion of the soil, and similar results were obtained in the Rawatpur States managed by Mr. Harrison, Assistant Collector. On the other hand, surface feeders, as the millets and other cereals, derive but little benefit, the first year from deep cultivation, or even suffer from the rawness of the newly-inverted soil. But the experiments conducted by Mr. Fuller with *sorgho* show that, for shallow feeding plants also, deep ploughing may be beneficial, if the freshly brought up soil *has had time to mature*, and with this object the land should be ploughed early in May immediately after the *rabi* harvest. The hot winds and sun during May and June have the effect of fertilising the soil exposed to their influence. —*Asian.*

LAND PRODUCE IN THE UNITED STATES.

AUTHORITATIVE statistics recently compiled show the extremely productive character of certain States in the American Union. It appears that a group of States with less than a third of the population of the country produces five-eighths of the corn supply of the United States. These States are Ohio, Indiana, Illinois, Iowa, Missouri, Kansas, and Nebraska; and the following figures will show the enormous progress which has been made within the limits of a generation. The corn growth of Ohio in the year 1859 was 73,543,190 bushels, and in 1877, 97,000,000 bushels. The produce of Indiana had gone up in the same period from 71,588,919 to 96,000,000 bushels; Illinois, from 115,174,777 to 260,000,000 bushels; Iowa, from 42,410,686 to 150,000,000 bushels; Missouri, from 72,892,157 to 103,000,000 bushels; Khansas, from 6,150,727 to 93,000,000 bushels; and Nebraska, from 1,482,080 to 33,000,000 bushels. In 1877 the product of these seven States was nearly 850,000,000 bushels, and of all the rest of the Union only 491,558,000 bushels. Mr. J. R. Dodge, of the United States Agricultuarl Department, says that the wheat surplus is produced entirely in that portion of the country north and west of the Ohio river, in the central area lying between that river and the lakes and the Alleghany and Rocky Mountain ranges, and in a smaller area on the Pacific coast. There has been a great transfer of corn production from the South to the West, so much so that, while in 1849 fifteen Southern States produced 59 per cent. of the corn product of the country, the whole of the South now produces only one-third. This change is partly due to the increase in the cotton product of the South, but it is said that the South may yet regain its supremacy in the corn culture. It is a surprising, yet authenticated, fact that in fifteen years the production of wheat and barely in the United States has trebled; that of corn, cotton, and tobacco has more than doubled; oats have increased by two-thirds, potatoes have nearly doubled, and hay has increased by nearly one-third.

Mr. R. P. Porter observes that it may surprise many to find that only about 9 per cent. of the total American grain product, by bushels, is exported. But this is an immense item in the world's markets, and with cheapening transportation is capable of being greatly increased. Of corn as yet only about 6½ per cent. of the total product is exported, yet this is nearly double what it was ten years ago. But the figures as to the exportation of bacon and pork are astounding. In 1868 the exportation of bacon and hams only amounted to 48,059,604lbs., whereas in 1878 it had risen to the enormous figure of 592,814,351lbs. pork had gone up in the same period from 28,090,133lbs. to 71,889,255lbs., and lard from 64,555,462lbs. to 342,667,920lbs. But in addition to this, the exportation of live stock across the Atlantic has increased tenfold within two years only. The cost of transporting live animals across the Atlantic is being rapidly reduced; yet the only hope for the British and Russian farmer is the high rates of transportation from the United States ports, and the fact that the American farmers, through bad farming, are exhausting the soil. Such are the present arguments on this question; but it is affirmed that, in the area yet to be subdued between the Missouri and the Pacific coast, the proportion of the cultivated area devoted to wheat will be larger than in the territory already occupied. When all these available lands are taken up, remarks Mr. Porter, and population threatens to press upon subsistence, fertilisation with rotation will increase the rate of yield (as has happened in the most populous districts of Europe), and then the centre of wheat production may possibly recede slowly eastward, obedient to the impulse of improved agriculture. With regard to the 'railway monopoly,' it is alleged that this is not such an obstacle as some may imagine. The Western producers affirm that they will not give up the battle until equitable and steady rates of transportation are insured. As it is, during the season of 1879 grain was shipped from Chicago to Liverpool for 17 c. a bushel, a rate but little in excess of that which prevailed for the transportation of grain from Buffalo to New York by canal and the Hudson River ten years ago. Mr. Porter observes that careful estimates shew that the United States is capable of maintaining an area of 200,000,000 acres of corn land, which, with the average yield of the past ten years, would yield upwards of 5,250,000,000 bushels of corn. Turning from corn and wheat to cotton, it appears that the whole cotton crop of the world could be raised on a section of Texas, less than one-twelfth of its area; or could be divided between any two of the other principal cotton States without exhausting one-half of their good land. The agricultural productiveness of America is practically illimitable; and when the full importance of the agricultural interest is realized and profited by, it must exercise an important influence over England and the European continent.

THE NEED OF AGRICULTURAL TRAINING.

THE native "Farmer," whose letter on Agriculture in India we publish in another column, endeavours to show that it "is incumbent on the rulers of the country to give their earnest attention to the dissemination, among all classes, of a sound agricultural education." Our correspondent probably refers to all classes of the ruled; and it may not have occurred to him, that the class which stands in most need of the education referred to is the governing class. What is the real cause of the apathy that is shown by the Government in promoting the kind of education referred to? No pains have been spared to make Masters of Arts, Bachelors of Arts, and clerks for Government offices; but few pains are bestowed on teaching the people the agricultural wisdom. The basis of the Empire is not found in what passes for scholarship, but in agriculture: and the security of the Government, the well-being of the people, and the prestige of England, are bound up not with the generous production of graduates, but with the conservation and development of the agricultural wealth of the country. Yet, from the Viceroy downwards, European officials in this country, with few exceptions, seem to draw their salaries without giving a thought to the fact that those salaries are for the most part derived from the soil, and that it is incumbent upon the recipients to make some return to the soil for the personal benefits received thereform. No dallying with agriculture is to be thought of, nor do we desire to see officials making of the subject a hobby-horse similar to the one called education, on which, until lately, it was the fashion of officials of high degree to prance. The inexperience or apathy of the European officials is naturally reflected in an aggravated form by their native satellites, and it is reasonable to suppose that, when the former have more experience or practical knowledge at their command, the latter will do their best to follow suit.

The recognition of the need of technical agricultural training in the officers charged with the collection of the revenue from the land, is one of the many good features of the Famine Commissioners' report. The Commissioners considered that it was unnecessary for them to dilate on the importance of agricultural knowledge, both to the governing class and the governed. On this point, we take the liberty of differing with them. We believe that if there is one subject more than another, on which the Government of India and the minor Administrations need to be periodically stirred up, it is that of agriculture. Theoretically it is admitted, that agriculture "greatly preponderates over all other interests and employments in which the people of India are engaged;" but in practice the subject, though of vital importance to the country, is approached in a half-hearted way, and is soon wearied of. One of the chief causes of this is the short-sighted system of giving the prizes in the service to good scribes rather than to clever administrators. Men, comparatively young in the Civil Service, who may be warranted to a great deal of epistolary work, are drawn away from the Mofussil, to the head-quarters of the Government, and there they remain till the end of their official days, while men who are working up-country are to a great extent forgotten. Our present Governor is a case in point. He knows a good deal about the details of Government, about rules, precedents, orders, regulations, and so forth; but it is probable that since he left Canara in March 1854, he has seen no more of the processes of agriculture, than what he could not avoid seeing in the neighbourhoods of the Adyar, along the line of railway to the Neilgherries and at Ootacamund. He is for a time, the chief ruler of a country containing thirty millions of people, mostly agriculturists; yet it would be ludicrous to claim for him the possession of the technical agricultural knowledge that "can be called in to enable the productive powers of the soil to be applied in the most effective manner, not merely to add to the wealth of the country, but to secure a food-supply which shall keep pace with the increase of population." The Commission being composed for the most part of officials, naturally perhaps came to the conclusion, that there is nothing like a department for putting to rights the ignorance of the governing class on agricultural matters. We cannot follow them here. India is already the hot-bed of departments, and what she now wants is not any more corporate associations "with no bodies to be kicked, or souls to be damned," but practical individuals, who know what they are about who do not dread responsibility, and who have minds of their own. A

department is an admirable arrangement for paying large salaries for plausible reasons to mediocre individuals whose work is not always worth the large sum the country pays for it.

The Commissioners consider that there should be in the country "a certain limited number of persons possessing superior technical and scientific knowledge of practical agriculture, whose task it should be to aid the Government in its endeavour to introduce improved methods of cultivation." Why do the Commissioners wish to limit the number of these superior persons? Are they afraid of having too much of a good thing? The Commissioners indicate some of the work that might be done by the persons aforesaid in ascertaining the characteristics and capacities of soils, &c., and they then proceed to point to the need of "a body of public officers with sufficient training in scientific agriculture to see that the special and technical knowledge just spoken of is applied in the best way, to interpret instructions to the people, and to stimulate popular sympathy and interest in the efforts made to introduce them." Of course they recommend the employment of trained Civilians. They suggest that for the future more weight should be given in the competitive entrance examination to the attainments in the natural and physical sciences. The requirements in Indian languages, Indian law, and political economy might, they consider, be abridged, and the place of these subjects should be taken by agricultural and organic chemistry and botany. They urge that after two years' special study; selected candidates should be allowed to spend one year either at an agricultural college, or in the study, under proper supervision, of practical agriculture. They recommend that junior Civilians who have served four or five years in India, should be allowed to spend a year or longer in Europe, at a school of agriculture, the time counting as service in India, provided they pass a suitable qualifying examination at its close. This is, we believe, what it most wanted. Men who have entered the Civil Service, and been knocked about the country a good deal, may be expected to have learnt that the special course of study through which they struggled in England was ill-calculated to arm them for the battle of official life in India. It does not take long for the "Wallah" to discover that he had to put himself to great trouble to learn something about a lot of things which are of no use to him in India, and that he stands in daily want of an unpretentious acquaintance with the common facts of daily life. If he have good stuff in him, the discovery of his ignorance prompts him to exert himself to supply his deficiencies; but hitherto the Government have not come to his rescue nor have they offered him any suitable encouragement to fill up gaps in his experience that hamper with his discharge of duty. The Government have however taken a step in the right direction with regard to Forest and Irrigation officers going to Europe to work up their special subjects and a comprehensive scheme to encourage revenue officers to do the same, should be of immediate benefit to the country, and to the Civil Service. It is the "little knowledge" that "is the dangerous thing." A technical agricultural training for young Civilians before they come out should be regarded as indispensable; but it should if possible, be supplemented by a special course of study in Europe after a few years' service in India. The crude ideas of youth, would, by that time, have been corrected by actual acquaintance with India. If instead of 917 Civilians, only a small percentage of whom have had a special and technical agricultural training, India had 1,200 Civilians, of whom fifty per cent. had passed through a thorough course of agricultural education, and if the sum divided in salaries among the 1,200 amounted to no larger sum than is at present drawn by the 917, then would there be a fair chance of the preponderating interests of agriculture being duly recognised by the Government. The country can ill afford to wait until a new race of Civilians rises up who have had the special training in their youth that is necessary for the proper encouragement of agriculture. The men already in the Service, and who are likely to remain in the country for ten years and upwards, engaged in revenue work, should be urged by Government to follow the example of Mr. Pennington, who, on the eve of being appointed Collector of Tinnevelly, went to the Agricultural College at Cirencester to learn what he had seen it was essential a revenue officer in India should know. Proprietors of large estates in England do not usually appoint as their land agents, or stewards, men whose heads are crammed with odds and ends of school knowledge; but they select men learned in land, who have made the cultivation of land their study from boyhood, and who have had practical experience of agricultural processes. The Government of India, on the other hand, though they are proprietors of enormous estates, have hitherto committed those estates to the care of stewards who have had no training in agriculture, but whose best energies have been devoted to getting up a variety of subjects that have no bearing upon land. The Government are so far consistent that they often appoint to District Judgeships gentlemen who are not learned in the law, and who have not made law their special study. This is because good appointments are found for men more often than good men for appointments.—*Madras Mail.*

HOW TO LEARN BOTANY.

BOTANY is usually regarded as a very dull and difficult study, even for advanced students, and of course quite too dry and hard for young children. This is all a mistake. Botany is really almost fascinating study for children or grown people. It is better adapted than almost any other to cultivate the very faculties which are not stimulated by other studies. The secret of success consists in making each student an independent explorer and discoverer. Taught by an enthusiastic teacher, botany awakens and strengthens powers of accurate observation, acute perception, and correct classification, such as are needed to make life useful and happy.

The study of botany may be commenced at any time. The best time is early spring. Suppose we start with a family of young people from 7 years old to 20. We meet every day. For our first lesson we study any plant or part of a plant, that we have at hand. Each makes a sketch on paper, and writes a minute description of it. Then we put some seeds, or grains, such as beans, corn, oats, &c., in warm water to soak till the next day. At the second lesson we open some of these softened seeds and observe their internal structure. The older and wiser ones tell the younger ones what they know about the seeds. Then we plant the remainder, some in earth and some between layers of damp cotton floating on a tumbler of water. While waiting a few days for these to sprout, we bring up from the cellar onions, potatoes, celery cabbages, &c. Each object is examined externally and internally, sketched and described in writing. Some of them are planted in earth and put in warm places, that we may study our growth. Looking out of the windows, we examine each tree and shrub in sight sketching and describing twig, branch, trunk, and bark, and kelling bud. We cut cross sections, and compare them with cross sections of bamboo or palm stems as seen in common fans. We cut vertical sections, and compare them with the wood used in making furniture. The plants and flowers in the window are sketched and described down to the most minute particulars.

Now we begin to study a book on botany. Our seeds are beginning to germinate and illustrate the first lessons, and our leader takes care that in all our course our investigations shall keep in advance of our book lesson, that we may have the pleasure of making discoveries, and finding them confirmed. Each day we recite something previously learned, find plants to illustrate it, and others to lead in the direction of the next lesson. Then taking some plant (if possible, a complete one from root to flower and seeds we examine, sketch, and describe it. Then turning to the analytical table) we trace the description till we determine the species. We commit to memory and recite some of the distinguished characteristics of the family thus becoming so familiar with them that in future we need not go through with the tabular analysis. We press and preserve specimens of all plants analyzed. As often as possible we pursue our studies in the fields and woods. In each of these excursions we study one particular organ or part of a plant. Sometimes collecting the greatest possible variety of leaves, we sit down and compare the different forms. Some times we do the same with roots. Thus we learn a great deal about plants which we cannot analyze, because some part is lacking.

In studying botany in the ordinary way, very little enthusiasm is awakened, but studying in the way described, vastly more interest is excited, and much more knowledge gained. A thousand beauties are discovered which the books pass over unnoticed. Any young person who has studied botany for a single season could conduct a class on the plant I have described. It is a shame that country children should be allowed to grow up ignorant of natural subjects around them. It is time that educated people, school boards, &c., should see sciences worth studying. Agricultural societies would help to educate the the young people if they would offer premiums for proficiency in natural science, as well as for cattle, crops, and manufactured articles.—*Teacher in Country Gentleman.*

WELL CONSTRUCTION ON ESTATES.

A CIRCULAR emanates from the local Government, enjoining that the construction of wells and other agricultural improvements on estates under management should be encouraged by district officers as much as possible. The circular in question goes on to remark that the Lieutenant-Governor and Chief Commissioner, has repeatedly, in his annual reviews of the revenue administration, in his orders on the budgets of wards' estates, and elsewhere, dwelt on the importance of encouraging, both directly and indirectly, the construction of wells in estates under management, and of treating liberally tenants who are ready themselves to make such improvements. Further in February 1878, he pointed out how far, in his opinion, it was admissible to restrain a tenant in respect of the making of improvements; prohibited the practice—of which some instances had been discovered—of requiring tenants, applying for permission to make wells, to sign agreements, resigning all claims to compensation as a condition of granting the permission; enjoined the grant of liberal terms to tenants desirous of making wells; and insisted on the advantage of distinctly recording those terms at the time they are agreed on. It has, however, come to his Honor's notice that his expressed views on certain points are not as fully known to the subordinates estates' officials and to the tenantry as they should be. Sir George Couper therefore deems it advisable to re-state his instruction on these points. The construction of wells and other improvements by tenants should be encouraged as much as possible, and it should be made known widely amongst the tenantry of estates under Government management, that this is the policy of Government, and that applicants need not fear that unreasonable restrictions will be imposed upon them. On the contrary, so far as the circumstances of the estates will allow, they will be aided liberally in making real improvements,

either directly with money or material, or indirectly by the [illegible] of a long lease of the land improved, or the assignment of land [illegible], or by the loan of money on favourable terms, or otherwise as may seem best. His Honor considers it is unnecessary to say much re [illegible] occupancy-tenants: they are few in number, and it is not usual [illegible] in any way with the exercise by them of their discretion as regards the making of improvements. If it is possible to afford them either direct or indirect assistance in carrying out works of this kind, it should be readily given; and if necessary, an agreement should be taken, re[illegible] nature and amount of the aid given, and the conditions on which it is given.

As regards tenants-at-will, there is no objection to the entry in the *patta* given to, and the *kabuliyat* taken from a tenant of this class, of a stipulation that the previous sanction of the officer in charge of the estate must be obtained to the making of an improvement; and that, if this is not obtained, the tenant will have no right to compensation for the work done without authority. But care should be taken to make the [illegible] understand that this is all that is meant. Under no circumstances [illegible] ever should a tenant, applying for permission to make an improvement [illegible] required to enter into an agreement, renouncing unconditionally all claim to compensation in respect of the improvement. If there are good reasons for refusing the application, this course may, of course, be taken, the grounds for refusal being placed on record for future reference; otherwise leave should be given. Where no assistance, direct or indirect, is given to the tenant, the order allowing the improvement to be made should [illegible] approximately, the sum to be expended and set forth that the tenant will, in case of dispute, be entitled to compensation up to this sum or [illegible] according to the provisions of the Rent Act. Where assistance in any shape is given, its nature and extent should be [illegible] recorded [illegible] the time permission to carry out the work is given, and the tenant may be required to enter into an agreement specifying how far [illegible] as a set-off against any subsequent claim to compensation.—[illegible]

INDIAN WHEAT

WHEAT in India is chiefly cultivated in the North West, [illegible] statistics available on the subject refer [illegible] when we find that in the Bombay Presidency [illegible] under wheat, 13,855 in Mysore, 612,26[illegible] in [illegible], 10,285 in Assam, and 1,602 British Burma. [illegible] consequence of the permanent settlement, the [illegible] the collection of statistical information concerning the actual area under cultivation with the different kinds of crops, coming to the higher latitudes, we find that here were 1433[illegible] acres [illegible] tion in the Central Provinces [illegible] than 6,900,[illegible] 2 acres. A "supplementary report on Indian [illegible]" which has just been presented to Parliament, makes [illegible] facts interesting. The report on Indian Wheat [illegible] Watson in 1879, contained definite allusion to the prevalence of [illegible] in the samples sent to England for valuation from the Punjab and [illegible]. In consequence of this a second series of samples were forwarded from the Punjab during 1880 for supplementary valuation and report. [illegible] samples sent numbered 192 in all, from sixty-two different parts of the Punjab, and although some of these samples were weevilled, they were not destroyed to such an extent as to prevent their approximate valuation, while the majority were in excellent condition. A few of the prices ruling in Mark-lane at the time of this second valuation may [illegible] English red (per imperial quarter) 39s. to 43s., and white, 42s. to 47s.; Nicolaieff and Odessa Ghirka (per 496lbs.) 42s. to 46s., Australian, 50s to 51s., white American and Canadian, 46s. to 48s., red winter, new, 47s. to 48s., and old 50s. to 52s., and of Indian wheats, other than Punjab, Calcutta No. 1 white, 48s. to 49s.; Bombay red and white, [illegible] to 50s., and Kurrachee, 44s. to 46s. The whole collection of Punjab samples were classified by the expert who valued them as follows:—

Denomination	Value: 48s 6d. and above.	46s. 6d. to 48s.	46s and under
A.—Soft white	17	11	..
B.—Hard white	17	40	10
C.—Soft red	3	22	6
D.—Hard red	1	36	22
	38	114	38

These with four samples classified as mixed, make up the total of 192 samples. The supplementary report, referring to this classification, says:—"By computing the whole of the 192 samples at the rates quoted, always taking the lowest value where the range of 6d. or 1s, is allowed, the result is a very satisfactory one, as it gives an average value per quarter of 46s. 10½d. against 39s. 6d for the whole of India in the previous valuation, or an advance of 7s. 2½d which cannot be all attributed to advanced prices." Only seven samples were valued at or below 41s. 6d., which is scarcely 4 per cent., whereas in the previous valuation fully 14 per cent. of the total of samples valued were below 37s. per quarter. In the case under report most of the inferior samples were sent from Dera Ghazi Khan and Dera Ismail Khan, the low prices being occasioned by the "dirtiness" of the samples, the term "dirty" including an admixture of barley or other grain.—*Times of India.*

PUNJAB WHEAT.

THE Punjab has long had the reputation of being a great wheat-producing country, but as yet it has not taken any conspicuous place as exporting beyond sea. There has, however, never been a famine in India which did not cause a sudden activity in the markets here, and we need only recall the extraordinary state of our railway stations in 1877-78 to show the capabilities of the country in cases where export paid even a little. It is handicapped to a considerable extent in competition with other provinces by its distance from the sea, but the Indus Valley is fast supplying the missing link, and even with that little Egypt—Scind—this province will fully be able to hold its own. In 1878 came the Afghan war and this, combined with two years of natural scarcity, taxed the province to the utmost extent, but though we have had to complain of high prices and perfect stagnation of export trade we have not been reduced to such scarcity or assistance of other districts, and we may safely [illegible] that the strain had been tided over. The harvest this year, [illegible] not a bumper one has been very favorable, and from the high prices now ruling in the English market, it is not unlikely that after the rains a large export trade may spring to life. In 1879 specimens of Punjab wheat were sent to England to be reported on by experts; but it appears that these specimens arrived in such a weevilled condition, that it was almost impossible to form a general opinion on them or on the capabilities of the province. Last year, however, greater care was taken, and although some were weevilled, the specimens were generally satisfactory. The prices for other wheats, at the time these were valued, ranged in England from 41s. to 50s per quarter of 480lbs. Some Australian and Pomeranian wheat fetched 51s, but 50s may be called the maximum. This was an increase over the price of 1879 of about 1s. 6d per quarter, but in Russian Ghirka wheat the advance was as much as 8s. This wheat has the peculiarity of greatly resembling Punjab hard red wheat, and it is an instructive fact that the Punjab specimens were also valued at an increased rate in 1880 of about 7s 6d on the quarter. Indian wheats, not yet having acquired local names in the home market are divided into soft white, hard white, soft red, and hard red. There were [illegible] samples of soft white. These ranged in value from [illegible] 6d. to [illegible], equalling the very highest classes in the market, *viz* American, Australian and Chilian. Of hard white there were 67 samples ranging from 47s to 50s. From this lot we exclude five samples from the Derajat, which were valued at from 32s. to 40s on account of being very dirty and mixed with large proportions of barely.

A quarter of wheat, about six maunds can be purchased here for 11 or 12 rupees, equal to 25 shillings at home. Added to this, there are small charges for bags commission, and brokerage, then there is railway freight to Kurrachee and shipping home, with some small broker charges at home. What the whole charges amount to we cannot tell at present though we believe they are not proportionately heavy, and in any case, this favorable report on Punjab wheat will not unlikely give a considerable impetus to exportation if dealers find that even a shilling or two can be made on the quarter. Two pice on the maund is sufficient here to wake the bunniah from the gorged boa constrictor state, into the most surprising activity.—*C. & M. Gazette.*

BAMBOO FOR PAPER-MAKING.

CONCERNING bamboo as a material for paper-making, the Trinidad (West Indies) *Chronicle* says:—"There are inquiries in town from America, and these lately were from England, as to our capacity to furnish a large and continuous supply of bamboo for paper-making. No difficulty in the least. It's here by the hundred thousand tons—a nuisance in its voluminous growth and practical ineradicability. We can ship it to any extent, at a week's notice. But, *cui bono?* It wouldn't be worth the freight, and if carried for nothing, the ripe stems would be so intractable that, with the earthy matters clinging to them, they would, as Mr. Routledge found, be more trouble to the manufacturers than the fibre prepared from them could pay. No paper-maker would touch the unprepared or even the crushed dry stems. What they want, as clearly laid down by Thomas Routledge, of Claxheugh, Sunderland, is paper stock or semi-manufactured stuff, to be prepared by crushing, retting, and combing by means of fitting mechanism at the place of growth—the material to be the young unripe shoots within a certain age (which we do not recollect at the moment)—so that a constant plant ng must be kept up and no bamboo be allowed to pass that age. Then, as paper material is a low priced article, far below the value of flax or hemp, this paper stock must be produced at a very moderate cost. The theory of the business is simple, and its requirements easy to master: but it will be seen that capital and mechanical skill are needed; that there is, in fact, a good deal to consider and contrive and that an eye to cheap production is a most essential requisite. Once the paper stock is made at a reasonable price, perfectly dry, and baled in pressed bales as wool or cotton is, America is our great market that can rid us of any quantity we are likely to make if ever so largely gone into. England, too, on same terms, could take very large quantities, for, as Mr. Routledge has shown, no better paper material can be desired for general uses than such as he has made from bamboo fibre under adverse conditions of manufacture. A very large opportunity is open for an ingenious man (or many) to make a fortune [illegible] a simpleton will assuredly burn his fingers and mayhap give a bad name to a new and excellent staple."

AGRICULTURAL PROSPECTS IN BURMAH.

THE local Government has recently drawn up and submitted to the Secretary to the Government of India in the Home, Revenue, and Agricultural Department a long and interesting minute on the condition generally, and prospects of agriculture in this province, as the result of the Chief Commissioner's visit to all the districts of British Burmah, and in which the following statistics of agriculture appear:—

Population, *about*	3,700,000 people.
Total area	87,220 sqr. miles.
or *about*	56,000,000 acres.
Cultivated area, *about*	3,900,000 „
Area growing rice	3,300,000 „
Computed total yield of paddy, or rice in husk *about*	2,361,000 tons a year.
Average yield of paddy per acre, *about* ...	32 baskets or bushels.
equal to ...	1,600lbs
Number of cattle, including buffaloes which are used largely for agriculture ...	1,153,000 head.
Number of carts	225,000

Besides rice the areas of the principal crops in the province, according to the latest returns, *plus* 15 per cent. as above are—

Mixed fruit-trees	130,000	acres,
Danee palm (used for thatching and also extracting sugar)	30,000	„
Tobacco	20,200	„
Plantains	17,100	„
Vegetables	17,000	„
Areca nut	14,100	„
Cotton	10,900	„
Pulse	9,900	„
Sugar cane	5,900	„

Of course as rice forms by far the largest item of agriculture, the whole burden we might say of this minute or letter is about that product, for in recommending the establishment of an Agricultural Department in Burmah which would afford encouragement to various branches of agriculture, such as tea, coffee, cinchona, cotton, tobacco, garden produce, &c., the remark is made that "whatever an Agricultural Department might do in promoting or helping the introduction or extension of new products, the chief attention of the department would in the first instance, be devoted to rice, which is the great staple of British Burmah." The minute observes that "it may be doubted whether English agriculturists have much to teach the Burmese regarding the culture of their rice fields" and points out the chief usefulness of an agricultural department would consist in inducing the cultivators to adopt labour saving machinery and other improved appliances for ploughing, sowing, reaping, and winnowing the rice crops especially as labour is both scarce and dear in this province.

From the foregoing figures it will be seen that the computed total yield of paddy is about 2,361,000 tons a year; the minute shows by some calculations given that this quantity only about represents the requirements of the province itself, allowing so many pounds a year for each individual and cattle as well as for seed grain. Certainly there is ample scope for the expansion of the rice trade considering the very high prices obtained, and the fact that of the whole are only 6 per cent. is devoted to the rice cultivation.

To give effect to these views the Chief Commissioner who has made provision in the Budget for 1881-82 to the extent of Rs. 45,000, recommends the appointment of a Director of Agriculture holding a position analogous to that of Mr. Buck in the North West Provinces on a salary of Rs. 1,000 rising to Rs. 1,500 by annual increments of Rs. 100; also a Consulting Engineer whose duty as a supplement to his other labours under Government, will be to advise and assist the Directors in the introduction of suitable labour-saving machinery. His remuneration for this part of his duties will be Rs. 200 a month. If this arrangement meets with approval, Mr. R. Gordon, Executive Engineer in charge of the Hendasa embankment division will be appointed, and one better fitted for the work could not perhaps be found. His knowledge of mechanical engineering, he having passed through the workshops of a Mechanical Engineer at home and also closely watched the progress of this branch of engineering in America, eminently points him out for the post in question, and we are likewise glad to see that Mr. Bernard has been able to do justice at last to a meritorious officer. As it is proposed to start a model farm on the land now being taken up close to the Reformatory at Poungday, it is intended to make the services of the boys of the latter institution available for the farm, a dove-tailing of ideas and projects which is certainly to be admired.

There is no mention whatever in these proposals for agricultural improvements about a stock farm, a matter which affects in a most important degree the dearness of provisions and consequently of labour to a certain extent, for dear provisions are identical with dear labour; but we presume this will come with the model farm and a Director of Agriculture, who must recognise the importance of this department of agriculture on the well-being of the province.

Attached to his minute of the local Government is a memorandum of Mr. Hough, the Secretary to the Chief Commissioner, in the Settlement Department bearing on the matters touched upon, displaying considerable shrewdness and a knowledge of the people and their requirements which we hope to refer to in another issue.

In the mean time we may conclude by remarking that we must regard the foregoing matter as another indication of the active interest in the welfare of the province which Mr. Bernard has evinced ever since his arrival here.—*Rangoon Gazette.*

DECLINE OF THE EARTH'S FERTILITY.

IS the cultivated soil of the world steadily declining in fertility by the constant and long-continued succession of cropping? Countries of once fertile land, such as the valley of the Euphrates, and Palestine have before this apparently been exhausted, and have reverted to barrenness. In a series of excellent papers Mr. J. B. Lawes, F.R.S., argues to the conclusion that profitable farming involves a slow but common exhaustion of the soil, and that, as regards the relation of landlord and tenant in Great Britain, rent may be said to be paid for the right to remove without restoration, a certain amount of the stock of fertility in the soil. Mr. Lawes is a man of ability and unwearied research; but it may just be that he is wrong in his original premise that nitrogen is the sole source of fertility in land, and, if so, his deductions cannot be correct. His arguments have brought him to the conclusion that draining, fallowing, liming, and the use of mineral manures do not benefit land, except in the sense of being so many means of liberating, and making available for the growth of crops, the stock of nitrogen in the soil—and that such appliances increase the produce of the land, at the expense of its stock of fertility, and thereby hasten its exhaustion. Mr. Lawes compares the fertility in the soil to the coal in a mine, neither of them being of any value till they are turned to some useful purpose, but that cannot be attained without a diminution of the original stock. He says that the various restrictions as to course of cropping, inserted in leases, are made for the purpose of limiting, as much as possible, the tenant's removal of this stock of fertility. He admits that the use of manures containing nitrogen, such as that made in the farm yard, retards the process of exhaustion. Large quantities of cattle food also are imported, and find their way to the manure heaps, but he reckons that these are too small to have any effect on the general fertility of the country, and that an addition of only 1 lb. of nitrogen per acre to the 31,000,000 of cultivated acres of Great Britain would require an import of 500,000 tons of grain and cake. He states that the conclusion he has drawn from the experiments he has long conducted at Rothamsted near Harpenden, Hertfordshire, do not tend to lessen the difficulties to be contended with in providing food for the millions of India. In Britain the exhaustion of the soil is delayed by drawing manures from all parts of the world; but in India no external sources of fertility are available, so that a decline of produce is slowly but surely taking place, and as population increases, and waste lands and forests which now form sources of manure for the cultivated area, are broken up, the exhaustion will increase. Mr. Lawes is further of opinion that with the resources available to him, the native cultivator manages to extract the greatest possible produce from his soil, and that under the circumstances science has nothing to teach him.

Mr. Lawes seems to have overlooked this rather important circumstance, that, even if it may be assumed that the soil of India is being exhausted by over-cropping, it is only the surface soil that has yet been operated upon. The native plough does not do much more than scratch this surface, and when more powerful cattle are to be had, heavier ploughs can be utilised and the upper soil will be invigorated by admixture with the underlying soil which has as yet hardly been touched. Of course, if the cattle used in agriculture are never improved, the decay of the soil, which is apprehended by Mr. Lawes is inevitable, for the native is not in a position to manure his ground to any large extent. It is a bold assertion that science has nothing to teach him, but there is some ground for it. The native agriculturist knows what he is about, rather better than is readily admitted by scientific agriculturists. It was quite recently believed by the latter, that you had only to give this country an abundance of water to make it grow anything. But the native did not take as kindly to the water as we expected he would do. He declined to believe that he would be the gainer in the long run from freely using it; and experience has shewn, that mischief has been done by the encouragement that irrigation has given to over-cropping. But no one would therefore say, that the solicitude of the Government to promote irrigation works is thrown away. The protection that those works afford against the consequences of drought is alone sufficient to justify their extension. But care has to be taken that too much importance is not attached to the increase of the outturn per acre of the crops. There is a strong temptation which should be resisted to draw too largely upon the agricultural resources of the future. Increased outturns that are obtained at the risk of eventually rendering the ground sterile, cannot be regarded as a gain to the country. What India wants is not so much more crop per acre cultivated as more and better cultivated acres. The want of water is a terrible drawback in many large parts of the country, that are now classed as culturable waste. If the area of cultivation could be extended there would necessarily be more food produced for the population, which is increasing so rapidly that it is impossible not to regard the future of this country with alarm. If in 1881, it is as much as the country can do to

afford subsistence to its 200 millions of inhabitants, what will be the state of affairs sixty or seventy years hence, when, according to statisticians, there may be 400 millions to support. We many console ourselves with the thoughts that "sufficient unto the day is the evil thereof," and that if we do the best that circumstances permit for the 200 millions, we may, with a good conscience, leave our successors to grapple with the problem of feeding twice that multitude. But we need to be careful not to draw upon the resources of the next generation or two, in order to improve the well-being of the present generation. The soil is forbearing, long suffering, and generous; but its patience, or its endurance, is not inexhaustible; and after giving abundant warnings the land goes out of cultivation, and extorts the rest it needs, by refusing to further meet the requirements of man. We have been over Mr. Lawes's experimental farm at Rothamstead. He has a large field there cut up into strips which have been planted with wheat for many years in succession. There is one strip which has not had the benefit of any manure all that time, and there are other strips which illustrate the results of the employment of a variety of manures. The wheat raised on the unmanured strip is naturally a very poor specimen; but it is highly interesting, as showing how Nature looks to man to restore to the soil some of the substances that he takes out of it.

We have alluded to the desirability of extending the area of cultivation in India, and we turn to the Famine Commissioners' report for information as to the quantity of waste land that is culturable. We find that the Punjab contains about 105,000 square miles. Of this about 35,000 square miles are cultivated, 30,000 square miles are returned as "culturable waste," and about 38,000 square miles are unculturable. In the North-West Provinces and Oudh, the cultivated area is half, and three-fifths respectively of the total area. The united provinces contain 51,000 square miles of cultivation, 19,600 of culturable waste, and 29,000 of unculturable. In Bengal it is calculated that 85,000 square miles out of a total area of 144,000 squares miles are cultivated. The Central Provinces have an area of 114,000 square miles, of which 30,000 are cultivated, 40,000 are culturable, and 44,000 are unculturable. In Bombay proper (excluding Sindh and the Native States) the total area is 77,000 square miles, of which about one-third pays no revenue, or only a quit-rent, 30,000 square miles are cultivated, and there is "ample margin for the extension of cultivation, but there are no large blocks of good land awaiting settlers, as in every case the best land has been taken up already and the poorest remains." In the Madras Presidency we have a total area of 138,000 square miles of which 50,000 belong to the great zemindars, and regarding which not much information exists. About 35,000 square miles of Government lands are cultivated, and about 10,500 of waste are culturable. The Commission found that there are considerable parts of India "in which the population is so dense, that it presses closely on the means of subsistence, and here unless the existing system of agriculture is improved, so as to yield a larger produce per acre, there is no room for an increase of the population." But there "is in most villages scope for a slow and gradual extension of cultivation, of what is now under tillage, and outside the villages there is an immense extent of land, which is more or less got fit cultivation." Unfortunately "much of it is poor land, and when it is not poor, either the climate is feverish, or else the conditions are so different from those that prevail in the densely populated places from which emigration might be desired, or expected to come, that settlers would be alarmed and discouraged."

In conclusion we may remark that, if Mr. Lawes is correct in his premises and deductions, the world will require no violent convulsion to bring it to an end, as the population will gradually shrink, with the decreasing means of subsistence, into a starved, scattered, and diminutive race. Nature is, however, as Mr. Squeers remarked, "a rum 'un" and it is possible enough that in her arcana there are more secrets than the scientific philosophy of Liebig, or Lawes, or Gilbert have penetrated. M. Georges Ville, a French chemist of high standing after lengthened experience of the same nature as that of Mr. Lawes, has come to a different conclusion, and does not leave us in such a slough of despond as our English teacher. M. Ville is of opinion that by returning to the soil one-half of the nitrogen extracted by the crops, (the other half being supplied from the atmosphere) calcic phosphate, potash, and lime, all these substances being plentiful, we shall not only be able to prevent the exhaustion of the soil, no matter how heavy the crops may be which are grown upon it, but that we shall endow it with the maximum of fertility consistent with the climate and general local conditions. A translation of M. Ville's book is published by Messrs. Longman & Co., and it is well worth reading along with the remarks of Mr. Lawes. Both are able men, and neither have spared time nor money in experiments, which have led them to widely different conclusions. Probably the truth will be found midway.—*Madras Mail.*

ON THE PRODUCTION OF LAC IN HOSHIARPUR DISTRICT.

By W. Coldstream, C.S., Deputy Commissioner.

THE District of Hoshiapur lies between the Beas and Sutlej Rivers. Its surface is, roughly speaking, half plain and half occupied by the outlying ranges of the Lower Himalayas, corresponding to the Sivalik ranges east of the Sutlej. It may therefore be called a submontane district. Lac is produced in all parts of it, at least in the plains and in the valleys between the hills. It is more abundant in the latter.

It effects chiefly the Beri (*Zizyphus Jujuba*), and Kikar (*Acacia arabica*); but is also found on the following trees:—

Pipal	...	(*Ficus religiosa*)	
Siris	...	(*Acacia Sirissa.*)	
Barh	...	(*Ficus indica.*)	... Banyan.
Pilkhan	...	(*Ficus venosa.*)	
Lasura	...	(*Cordia Myxa.*)	
Anjir	...	(*Ficus Carica.*)	
Dhak	...	(*Butea frondosa.*)	
Phagura	..	(*Ficus caricoides.*)	
Patajan	...		
Gular	...	(*Ficus Cunia.*)	

Thus it is found on six species of ficus.

The lac produced by the various trees differs in quality. The lac produced on the *Zizyphus* is deemed the best, and next to it comes that produced on Sirris, Kikar, and Pipal.

There are two seasons for production—February to April, and July or August. The crops are collected in June, and October or November. The same tree is said not to produce two crops in the same year. The autumn or October crop is considered the more valuable of the two.

The artificial propagation of lac is understood by very few persons, but seems to be occasionally practised. The method adopted is to tie a small branch with the insects on it on the tree which it is desired to effect. The writer has found it very easy to propagate lac on Beri trees in this manner. The twigs containing cells of the insect, were tied on to the trees in July; shortly after the new swarm appeared and spread over the nearest branches of the tree. There appears, however, to be among the people a great dread of the tree being injuriously affected by the spread of lac upon it, and this is probably the reason why propagation is not carried on to a greater extent. In cutting lac off a tree a few twigs containing cells are allowed to remain to furnish a crop for next year.

There existed a deep and widespread prejudice among Hindus against having anything to do with lac. This was particularly strong among the Bhabras (called in other districts Saraogis.) Lac was considered a kind of disease or leprosy of the tree, and to be an unclean substance. Its red color and its animal origin are sufficient to account for this prejudice. It has disappeared, to a great extent, within the last ten years, owing to the great value which lac acquired in the market. There have been of recent years, many disputes in the Civil Courts as to the relative rights of landlords and occupancy tenants to take the lac from trees growing in an estate. The question was not discussed at the time of the Revenue Settlement of the district in 1852, lac having then but a small marketable value.

The crop of lac on roadside trees is sometimes sold by Government to a contractor, who is allowed to cut off twigs and branches of a certain thickness. In 1876 the lac on the roadside trees in Unah pargannah was sold for more than Rs. 400. The crop, however, varies much in quantity from year to year, as does also the value of lac in the market.—*Indian Forester.*

TUBERS AND ROOT CROPS.

IN Northern Europe, root crops are the chief dependence in feeding farm stock, or at least they were before the introduction of ensilage taught the art of preserving green crops from winter forage. Efforts at various times have been made to induce American farmers to substitute root culture for grain-growing on stock farms. Many persons remember the earnest efforts of Prof. Mapes, in 1855, to introduce the cultivation of the carrot as a food crop for wintering stock. In the West two serious objections lie against the proposed change, and these have confronted us in every attempt to substitute roots for grain as winter food for stock. The first of these is our climate. Root crops require a cool, moist summer, while our summer atmosphere has almost the heat and dryness of the tropics. The turnip in this country is a fall crop, while in England and in Sweden, the paradise of the turnip, it is planted in May and grows all the summer. In a less striking degree the incompatibility of our climate interferes with the successful cultivation of the carrot, the beet, and the parsnip. Our intense summer heat not only arrests the growth, but it converts the starch and the sugar of the roots into indigestible woody fibre. Most of the succulent vegetables of Northern Europe can be grown in our climate, only in the early spring, or late fall months. But in the case of root crops this interferes with the full development and proper maturity of the root, and with this come corresponding reduction of its food value.

The other objection lies in the delusion of large crops. Ten tons of turnips or carrots per acre looks like an enormous pile of food, but when we remember that 90 to 95 per cent. of this is water, we must reduce our crop to 2,000 pounds of solid food which corresponds to 40 bushels of corn; but this has less nutritious matter than a corresponding weight of corn. An occasional feed of turnips, beets, or carrots will serve as a relish for grain food in long continued winter feeding, but as a constant diet, root crops cannot be economically used where maize can be grown so cheaply as it can be in our soil and climate.

The potato is not, a root, it is a tuber, or underground stem with true buds on it. Its food value varies very much with the variety of potatoes

used. The weight of solid matter in 100 pounds of potatoes varies from 24 to 32 pounds; and this has nearly the same fattening value as a similar weight of corn, though a little less of the flesh-forming material. In comparing this with our standard feed-crop, 200 bushels of potatoes will correspond to 40 bushels of corn, but the maise is the more certain crop and requires no more labor in its cultivation, and less labor in preparing it for feeding.—*American Paper.*

THE JAPAN PEA.

THERE is nothing in the list of forage plants that excels the Japan pea for our soil and climate. T. E. Martin and R. T. Rutledge, both progressive farmers of our country, tell me that the Japan pea is the most productive as well as good food that they have ever grown, for all kind of stock; horses, cattle, sheep, and hogs will eat the peas, stems, and leaves, if harvested before fully matured and cured like other hay, with as much relish as they do corn. Then there is no pea for the table, is soaked in water the night before cooking, that has a more exquisite flavor. They grow on a stout bushy stalk from two to three feet high, somewhat resembling the cotton plant. The main stalk, as well as the branches of limbs, are literally loaded with small pea pods filled with little yellow peas, similar in color, size and flavor to the English garden pea. They can be grown with the corn crop very successfully, by planting a hill or peas between each hill of corn at the second ploughing, same as the ordinary stock or field peas. But the way to get the greatest yield is to plant in hills two and-a-half feet each way, allowing but one stalk to the hill to remain after the first working. That will give you 6,960 stalks to the acre, and on ordinary land, cultivated the same as corn, will average at the lowest estimate, a pint of shelled peas to the stalk, or a fraction over 108¾ bushels per acre. I doubt not that with high cultivation and good soil, it would be an easy matter to double that yield, besides there is no other crop that will yield more hay to the acre. In fact, I know of no crop so remunerative as the Japan pea. It is a sure cropper, as clearly demonstrated by my experience with this season's crop. Neither wet nor dry weather materially interferes with the quantity or quality of the yield. —*Mississippi Patron.*

THE BAHRAICH AGRICULTURAL SHOW.

THE Saiyud Salar Mela at Bahraich attracted, as usual, immense numbers of natives from all parts of the surrounding country, and has been celebrated with as much devotion as display by believers in the efficacy of a visit to the shrine of the time honored and departed saint. The fair this year had an unusual attraction both for the European as well as the native community, in the shape of an Agricultural Show, wisely originated by the popular and esteemed Deputy Commissioner of Bahraich. It was the first of the kind, and like all new projects was we believe attended with grave difficulties at the outset,—which, indeed, at one time threatened to mar the complete success of the meeting; but it is a pleasure to find that both by the originator as well as those officers whose indefatigable labours made the scheme practicable, it was considered that the show was in every respect appreciated. It is hardly possible to overrate the benefits—remote and direct—which arise out of such meetings.

And the example set by Bahraich may be commenced to all the districts which have not as yet been enterprising enough to make the venture. Much if not all, of the success attending this Agricultural Show may be attributed to the skilful origanization of Captain J. Innes, the Secretary, who was left unfettered to plan as well as to carry out the whole arrangements of the fair; a task of no small magnitude, and one entailing so much mental as well as physical exertion that most men, at least in the month of May, would have declined it. It is certainly worthy of record that, owing to careful sanitary arrangements, not a single case of sickness occurred; and by the excellent supervision of the police merely two or three cases of petty theft were committed, the offenders being punished on the spot as an example to other would-be depredators. The site of the fair and Agricultural Show was well selected, and stood in the shade of mangoe topes about two and-a-quarter miles from the city.

* * *

Cawnpore presented an entirely new industry by Tuck Harvey & Co., affording a striking example of the fruits of enterprise as well as the resources at our command in the country. A well arranged case of soaps in bars and tablets, made on scientific principles from indigenous materials—and a *bonâ fide* vegetable production throughout —the basis of oil, colored with the products of plants and richly perfumed with their flowers. These soaps attracted considerable attention on account of their being suitable for use both by the orthodox Hindu as well as Europeans,—and the entire case was purchased by the Rajah of Nanpara.

A great curiosity came from Hurdui, exhibited by Mr. Naher—specimens of black and also white gram—never seen before in the Bahraich district. We were not informed whether there was anything peculiar to it besides the colour.

After a very agreeable time spent at the Exhibition (to which by the way admission was free to all comers) the visitors were invited to witness some good wrestling matches, which occupied several pleasant hours. Most of the wrestlers had come from long distances—Cawnpore, Lucknow, Benares, and even the Punjab. They were famous, yet they found in some of the Bahraich competitors a match of which the local wrestlers were not a little proud.

This pastime over, the crowds went to witness the trial of the water lift exhibited by the Department of Agriculture and Commerce, N.-W. P., and other implements of husbandry from various sources. The *Ploughs and Grubbers* shown by that department were perhaps the most worthy of notice. The natives, however appreciating a difference, exercised considerable discrimination in regard to these implements and the "Nawab" plough by Mr. Crawley of Cawnpore, for while purchases of only six were made of the former, fourteen of the latter were ordered on the spot.

A rather good winnowing or seed cleaning machine by the Department of Agriculture and Commerce, as exhibited by the Director, attracted attention, but no orders were registered for it, perhaps for the reason that it was only suitable for cleaning the larger grains and seeds. One is certainly required which will thoroughly clean all alike, large and small.

A mill for crushing sugar-cane was exhibited by Mr. J. Sinclair, agent for the patentees—Messrs. Thomson and Mylne of Beheea, and showed at a glance to the dense and admiring crowds its immense superiority over the ordinary native *kolu* or mill. We believe this machine was more appreciated by the Rajahs, Talukdars, and natives generally than any other implements exhibited.

The one shown was bought on the spot. The mill is simple enough and perfect of its kind. It most effectually crushes out the cane, leaving not a vestige of juice behind in the squeezed residue.

A visit to the cattle show completed the programme of engagements for the day. The ordinary breed of cattle in the district of Bahraich is superior to any in these parts of North-West India, but those exhibited were simply magnificent without exception—so much so indeed that selection for the prizes became no easy task. Talukdars of Bahraich have evidently given their attention to cattle-breeding from good stock, and have succeeded beyond their expectations; and encouraged as they have been in this matter they expressed at a meeting in Durbar their desire to effect still further improvements both in draught and plough cattle, if the Government would place at their disposal some suitable extent of its pasturage lands.

* * * *

On the 24th, at 7 A.M. another meeting was held in Durbar, when the various prizes were awarded by the Deputy Commissioner to those who had been adjudged successful exhibitors. Most of the prizes for cattle were awarded to Bahraich and its district. There was only one successful competitor from an outdistrict.

Among the agricultural implements, the "Nawab" plough was selected for the 1st Prize, which was awarded to its inventor, Mr. Crawley of Cawnpore.

In machinery, Messrs. Thomson and Mylne stood first on the list for their sugar-cane mill. The remaining exhibitors in this department were honorably mentioned. In cereals, there was almost a tie between the Bahraich districts and Hurdui, and the prizes were awarded accordingly. In manufactures Messrs. Tuck Harvey & Co, of Cawnpore, were selected for the 1st Prize. A large number of smaller prizes and "honorable mentions" were awarded to other exhibitors, but these need not be particularised.—*Express.*

* * * *

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Monthly General Meeting was held on Thursday, the 26th May 1881.
W. H. COGSWELL, ESQ., *President, in the Chair.*

THE Proceedings of the last Monthly Meeting were read and confirmed.

The following gentlemen were elected Members:—

Messrs. A. H. Collins, C.S., W. Innes, Alfred Bridge, J. Anderson, T. S. Anderson, H. E. M. James, C.S., James Paterson and T. H. Korswill; Lieut.-General Dhoje Narsingha Rana Bahadoor; T. C. Pande, Rajah of Pakour; and the Secretary, Public Garden, Bhagulpore.

The names of the following gentlemen were submitted for Membership:—

His Grace the Most Rev. Dr. S. Goethals, Archbishop of Hieropolis, —proposed by Dr. G. King, seconded by Mr. M. Rustomjee.

Baboo Shamlall Sen, Zemindar, Goureepore,—proposed by the Secretary, seconded by Baboo P. C. Mittra.

A. A. Shircore, Esq., Barrister-at-Law, Jullundur City,—proposed by the Secretary, seconded by Mr. H. A. Firth.

Lieut-General Umber Jung Bahadoor Rana, Nepal,—proposed by Lieut.-General Dhoje Narsingha Rana Bahadoor, seconded by Baboo P. C. Mittra.

S. Gowan, Esq., Sirajgung,—proposed by Mr. J. G Meugens, seconded by Mr. A. Wilson.

Edward Cleveland, Esq., Zemindar, Secunderabad, Zillah Bolundshuhur,—proposed by the Secretary, seconded by Mr. J. G. Meugens.

W. E. Crum, Esq. Merchant, Calcutta,—proposed by the President, seconded by Mr. H. A. Firth.

Hamilton Martin King, Esq., Goosbur and Barabanki Tea Estates, Julpigoree,—proposed by the Secretary, seconded by Mr. Meugens.

D. Cruickshank,—proposed by the Hon'ble A. B. Inglis, seconded by Mr. Wilson.

Dr. D. O'Brien, Romarie Factory, Debrooghur,—proposed by the Secretary, seconded by Mr. G. L. Kemp.

J. H. Barry, Esq., Merchant, Calcutta,—proposed by the Secretary, seconded by Mr. W. H. Cogswell.

W. Palmer, Esq., Examiner, Telegraph Accounts, Calcutta,—proposed by Mr. W. Stalkartt, seconded by Mr. J. F. Westfield.

Manager, Debrooghur Division, Upper Assam Tea Company,—proposed by the Secretary, seconded by Mr. Wilson.

Manager, Blackburn Tea Garden, Assam,—proposed by the Secretary, seconded by Mr. Wilson.

C. H. Moore, Esq., Merchant, Calcutta,—proposed by the President, seconded by the Secretary.

Rejoined—C. Brock, Esq., Calcutta, S. U. Phipps, Esq., Calcutta, and Rajah Kistorindra Narain Roy, Zemindar, Bolikar, Rajshaye.

CONTRIBUTIONS.

1. Records of the Geological Survey of India, Vol. 14, Part 1. From Government of Bengal.
2. Journal of the Bombay Branch of the Royal Asiatic Society, No. 38, Vol. 14. From the Society.
3. The Indian Forester, Vol. VI., No. 4. From the Editor.
4. Proceedings of Annual Meeting in March, and Proceedings for April 1881, of the Madras Agri-Horticultural Society. From the Society.
5. Journal Asiatic Society of Bengal, Part 1, No. 1 and Part 2, No. 1, and Proceedings for March. From the Society.
6. Memorandum on Dyes of Indian growth and production, by J. Liotard of the Agricultural Department. From Government of India, Department of Agriculture.
7. A few plants from Singapore, Orchids, Ferns, and Fruit trees. From E. Kock, Esq.
8. A small quantity of seed of *Sorghum saccharatum*. From Mr. R. B. West.

Mr. W. F. Westfield sent for inspection a plant of Bamia cotton raised from the seed which he has recently brought to the notice of the Society, and which gave so great an yield. The seed from which this

plant was raised, was sown in a large pot at end of February, and is now in a most vigorous state both flowering and podding : it is nearly 3 feet in height.

GARDEN.

A report was submitted by the Superintendent, of which the following are extracts :—

"There would have been very little of special interest to report this month, were it not for the severe storm on the night of 10th instant. The damage to well-grown plants in the orchard and ornamental plant portion of the garden has been considerable, very many trees having been entirely blown down. Such as are likely to recover have been propped up. The damage to the three plant sheds (covering 250 feet by 50 feet) was great, all of them having been blown down, &c. The plants which were sheltered under same have been considerably injured, one of the sections of shed to west of residence measuring 60 feet, 40 feet has been reconstructed since, and the rest will be shortly completed.

The glass houses suffered considerably by the storm as well, but have been repaired since.

The injuries caused by this storm, and time occupied in repairing damages, have necessarily retarded the distribution of plants to Members whose applications were registered, but we hope shortly to recommence work.

REPORT ON FLAX RAISED ON THE CAWNPORE EXPERIMENTAL FARM.

Submitted a letter from the Officiating Director, Department of Agriculture, N.-W. Provinces, and sample of the Flax therein referred to for an opinion as to its quality and value.

Submitted the following notes of the Fibre Committee thereon :—

Mr. W. H. Cogswell.—I consider this well grown and nicely prepared, of good strength, but the staple is very irregular in length and size, soft fibre and bright color, altogether a very good and most desirable product and easily saleable in the European markets and would command good prices. Some of it has been too much combed, imparting almost a towy appearance, and it would have been better had the sample been divided in order to separate the long from the short and irregular staple. Its value per ton is somewhat difficult to arrive at unless a large sample of it was sent to England ; approximately I should say it might be worth £35 to £40 a ton. No mention is made from what seed this has been grown, nor result per acre in weight. It would be desirable to give such details whenever samples are sent for report.

Mr. W. Stalkartt.—Sample dressed flax, long and short mixed, quality appears very good. As no other flax ever comes to his market, it is difficult to give a valuation. If all long flax it might be worth £35 to £40 in the English market.

Mr. S. H. Robinson.—I agree with the above remarks as to the want of regularity in the fibres, and their general character, but would not value them so high. Last month's Dundee quotations were £29 to £37 per ton, the latter for the *best* Archangel. Probably £30 to £32 per ton would be a more correct valuation, being the rate for good Riga.

MANILLA HEMP.

Read a letter from the Assistant Secretary, Government of Bengal, Financial Department, Agriculture, forwarding copy of a Memorandum by Surgeon-General Balfour, on the cultivation of Manilla Hemp in India, with reference to the Report by Mr. Liotard, of the Agricultural Department, on the materials in India, suitable for the manufacture of paper, and requesting the favor of any remarks which the Society may have to make on the subject.

The Secretary read the following note, and stated that Surgeon Balfour's Memorandum had been introduced in the Monthly Proceedings of February last :—

"From the Transactions of the Society, it would appear, that its attention was originally drawn to the Manilla hemp plant (*Musa textilis*) so long ago as in the year 1822 ; some useful papers regarding it were subsequently published in 1840. An attempt was made to cultivate this valuable fibre-yielder in the Society's old garden in 1836, but after trials for three or four years, the cultivation seems to have been abandoned. From this fact, it may be assumed, that it did not succeed, though there does not appear to be any record to this effect. It may be that Lower Bengal is too low for its profitable culture, for hilly land would seem best adapted for it. Attempts might be made to cultivate it in some parts of Upper Bengal (Monghyr for instance) where there is a fair elevation.

The Society would, however, be glad to renew the attempt in the spot, in its present garden, which has been recently set apart for economic cultures, if the Government would obtain a supply of plants from the Philippine Islands, or from the Andamans, where there is a plantation, on the produce of which a report was furnished last year by the Society."

In connection with the above, the Secretary laid on the table, applications from the Superintendent Botanic Garden, Sharunpore, and the Superintendent, Public Garden, Hoshungabad, Nurbudda Division, the former requesting plants and the latter plants and seeds of the Manilla hemp, plant and instructions in aspect to soil, mode of cultivation, &c. The Secretary intimated he had afforded partially the information required, and stated that there were no plants in the Society's Garden.

PLANTAIN FIBRE.

The next papers brought to notice were a letter from the Secretary, Chamber of Commerce, forwarding the specimens of plantain fibre with a letter from the Government of India, and requesting on behalf of the Chamber, a report on the same.

The following is the letter from the Government of India :—

"I am desired to bring to the notice of the Chamber of Commerce the accompanying paper* by Mr. Liotard, of this department, describing a process which he suggests for the extraction of the fibre of the Manilla hemp. It will be observed that it is also proposed to apply this process for the extraction of the fibre of the varieties of the Plantain tree which are found in hill tracts or elevated plateaux in India.

* Paragraphs 1 to 22.

2. Some fibre has been extracted by this process from the Bengal variety of the Plantain tree, called in the vernacular *kanch kella* ; and I am to forward herewith a sample of the fibre thus obtained for submission to the Chamber of Commerce. It is known that the fibre produced from this variety is inferior in quality to that of the upland or the Philippine species, besides being relatively less in amount ; but it has been operated upon because it was readily available with the object of putting the process suggested to a practical test.

3. The Government of India would be glad if the Chamber of Commerce would favour this department with its opinion on the value of the sample, stating whether it would be marketable as material for paper manufacture, or for cordage and textile fabrics, and what the price of the stuff would be per ton in this country and in England. I am also to invite any remarks the Chamber may see fit to make upon the paper by Mr. Liotard.

Note by Mr. W. Stalkartt.—These specimens are very prettily got up, are much too good for paper making, but might be useful for cordage. It is impossible to quote values on such minute specimens.

FIBRES.

The Secretary next called attention to some fibres prepared from certain Malvaceous plant (*Abutilion, Urena, Hibiscus,*) which had been forwarded by the Forest Officer at Kolhapore (Bombay Presidency) for report. He had informed him, in reply, that these were of little or no value, except for local purposes.

Letters were read—

From Clements R Markham, Esq., C.B., dated London, March 27th, in reply to an application for seed of Cuzco Maize and Quinua seed for trial in the Himalaya, as suggested by Captain Pogson.

"A good supply of quinua seed",—writes Mr. Markham,—"was sent out to the Government of India in 1874, which I obtained through Messrs. Antony Gibbs and Sons of Lima." Mr. Hume said it was *bathu*, but this is a mistake, *bathu* is the "Chenopodium album," of the Punjab, which grows on the plains and is not a hill product. Quinua is the "Chenopodium Quinua," which is cultivated at very great elevations. I suppose the Government gave a portion of the quinua seeds, sent out in 1874, to the Agri-Horticultural Society of India. [The Society did not receive any.] I trust this was so for I fear that, in the present state of affairs in Peru, it will be difficult to get fresh supplies for some time to come. All the chief ports are occupied by hostile Chilian forces, there is no communication with the interior, and many of the merchants have left. It is quite uncertain how long this will last, but I will bear in mind your wishes both as regards Cusco Maize and Quinua. Meanwhile I will consult Messrs. Gibbs as to the prospect of renewing communication with the interior of Peru.

From P. deLavol Lennox, Esq., of Bhawarees, Punjab, forwarding a quantity of leaves of a *Potentilla*, a supposed remedy in certain cases of cattle disease. This has been transferred to Messrs. O. Steel & Co. for division among their tea gardens which are chiefly affected.

From L. A. Berneys, Esq., late Vice-President of the Queensland Acclimatisation Society, tendering his best acknowledgments for election as an Honorary Member of this Society. I hope it will be remembered —adds Mr. Berneys—that my services are always at the disposal of the Society, and that it shall at all times be happy to receive and afford my best attention to any communications which may be addressed to me on its affairs.

GARDEN.

An experienced nurseryman writes :—"We have grafted thousands of trees with scions cut from bearing trees, and many other thousands with scions cut from young nursery trees from two to four years old, and have planted trees grafted with each in orchards and watched them for years, and could never see that the two kinds of scions made a particle of difference in any way. We think apple root-grafts made from the scions from healthy young trees make a better 'stand' than those from old orchard trees, and that such scions give a cleaner, healthier growth than scions taken from old orchard trees, simply for the reason that old orchards are, as a rule, full of these hidden microscopic diseases and parasites that are seldom found in fresh young nurseries. We believe there might be a slight difference in top-grafting in bearing trees as to early fruiting with scions taken from bearing trees, but we also believe that this extra early fruiting is not at all desirable in the long run. Young trees as well as animals, should grow, not bear, and we have often heard the views here given publicly expressed by our most observing horticulturists of experience."

SOMEBODY writes to a society paper about orchids. He says :—"I see 140 guineas was given for an orchid root at a sale last week, the purchaser being willing to take all the chances of accident or disease injuring it before it come into bloom. The special charm of orchids always seems to me to consist in their looking like a bad imitation of anything else than a flower ; they have neither *perfume nor beauty*, but they are, fashionable and therefore those who do not admire them had better learn to do so as quickly as possible." Whoever wrote this paragraph could never have seen a Ceylon orchid ! Anything more delicately beautiful or with a more delicious perfume, I cannot imagine.

CALIFORNIAN BEE CULTIVATION.

THERE is ground for supposing that there were no bees in the New World prior to the invasion of the European. The Indians agree that the busy little insect is never found far distant from the outskirts of civilisation, and there is a recorded tradition that the invasion of California by the backwoodsman was predicted by a warrior of the Gumas tribe, on discovering a bee-tree on the Gilla River. As civilisation advanced, however, its pioneers soon learned to value the honey; and a race of hunters grew up, who made it their business to track the flight of the wild bees to their nests in old hollow trees, and then, by smoking the bees out, and cutting down the tree or its branch, with a hatchet, obtaining the combs, which were carried away in buckets and tubs. It is only in recent years, however, that anything like bee culture has been attempted; but so rapidly has the system extended, that it has now become quite an important industry, more than thirty-five millions of pounds of honey being annually produced and sold in America. The trade is principally carried on by large capitalists who have often from 2,500 to 5,000 swarms of bees, and even larger numbers, one firm having as many as 12,000. Perfect organisation is necessary for the management and care of the little workers. In the United States the bees are "farmed out," *i.e.*; apiaries of say a hundred swarms are placed in the grounds of farmers, the distance between each apiary being generally from three to four miles. The farmers receive either a fixed rent or a share of the honey for the accommodation. The bee-owner has a staff of skilled workmen who clean out the hives and remove the boxes of surplus honey as they are filled. In addition to these experienced bee-men, occupation is afforded for many other people in manufacturing the boxes in which the honey is transported to the different markets, one firm alone, we believe, finding, finding employment for nine men and two steam saws during six weeks of the year in cutting up the timber for the 72,000 boxes which they require. The glass-makers also find some custom from the honey dealers, the slides and ends of the boxes being of glass. On an average one acre is estimated to support twenty-five swarms of bees, and the yield of a swarm is generally about 50 lbs. of honey; so that the trade is evidently capable of yet further development. Much attention is paid to the improvement of the breed of bees, and, with characteristic ingenuity, the Americans have introduced many contrivances to save the time and labour, not only of the honey dealers, but of the bees themselves.—*Graphic.*

USEFUL GARDEN RECEIPTS.

(From the Gardeners' Year-book.)

TAKE two parts of very dry lime rubbish and one part coal, ashes, also very dry, and both sifted fine. In a dry place on a dry day mix them, and leave a hole in the middle of the heap, as bricklayers do when making mortar. Into this pour boiling hot coal tar; mix, and when as stiff as mortar put it down 3in. thick to form the walk. The ground should be dry and beaten smooth. Sprinkle over it coarse sand; when cold pass a light roller over it, and in a few days the walk will be solid and waterproof. 2. An old gravel path will only require to be swept clean; a new-made one to be well beaten and rolled. Choose a warm day (the warmer the better); let the tar be boiling hot; use the common, long-handled, iron-bound tar-brush and iron kettle, holding about a gallon, for the purpose of taking only so much tar from the boiler at one time as can be used in about a quarter of an hour, and paint over with a good coat. Let a lad follow with dry sifted sand, throwing over enough to prevent the tar sticking to his feet, and then go over with the roller. Two men tarring will employ a lad to follow with the sand, and another to attend the fire and supply the tar as fast as used. This repeated every three years, the surface will become quite hard, and the paths will always be perfectly dry and pleasant to walk upon even in the worst of weather.

If iron garden tools are laid for a few minutes in a solution of soda they will be protected from rusting for a long time, even if exposed continuously to a moist atmosphere.

Take a large watertight hogshead, and cover the bottom with about 6in. deep of dry soil; on this put a layer of bones of the same depth, and cover them entirely with wood ashes; on these another layer of bones, then ashes, and so on till the hogshead is full. Leave it exposed to the rains all summer and winter till spring. Then on removing the contents of the hogshead, the bones will crumble to powder under a slight pressure, and form one of the most valuable manures ready for immediate use.

Coarse weeds such as plantain, docks, thistles, and dandelion, may be removed from lawns by the application of oil of vitriol. Take an old blacking-bottle with a wire round it to carry it by, and a stick to dip with. The stick should not be pointed, but notched round for an inch or two at the end, the better to hold the liquid. Just one drop quite in the heart of the weed is sufficient to cause death, and the notched stick will contain at one dip enough to destroy three or four plants. If the acid is good (it varies in strength), the work of death can be both seen and heard, for the vitriol hisses, and it burns up the weeds in a moment.

Grafting wax is very much used on the Continent for protecting newly-made grafts instead of the clay and horse droppings formed into a plaster, such as is used in this country. It is also of great service in covering fresh wounds in trees, made either by accident or design, and is a much more cleanly substance, as well as a more neat application, than the ordinary grafting clay. I have here furnished various formulæ for making the grafting wax or mastic, and as I have used them all at various times they may be relied upon to answer the purpose for which they are intended. The first five require to be melted in an earthen pot over a fire and to be applied warm, but not so hot as to injure the tissue of the bark with which it may come in contact. 1.—Rosin 1 part, yellow wax 1 part. 2.—Black pitch 5 parts, rosin 1 part, yellow wax 2 parts. 3.—Burgundy pitch 1lb., black pitch, 4oz., yellow wax 2oz. resin 2oz., mutton suet, 2 drachms. 4.—Yellow wax 2 parts, suet 1 part. 5.—Black pitch 1 part, yellow wax 1 part, suet 1 part, pounded brick 3 parts. The following has not the inconvenience of requiring to be applied warm, and may be prepared and used without being heated. 6. Yellow wax, [illegible], turpentine 1lb., Burgundy pitch 6oz., mutton suet 4oz. Melt all together and mix thoroughly, and leave them to cool. Form the mass into small balls, as it will not stick to the fingers, and use them when opportunity offers.

LIQUID GRAFTING WAX:—This is a very useful application and is perhaps, the most convenient for the purpose of all the mastics used for covering wounds and grafting, of the consistency of varnish, and is applied very thinly with a brush. Care must be taken not to lay it on thickly, for the surface hardens so rapidly the alcohol is prevented from evaporating. Rosin 1lb., beef tallow 1oz., spirits of turpentine 1 tablespoonful, alcohol (95 per cent.), 6oz. Melt the rosin over a slow fire, when melted take it off and add the beef tallow, stirring it constantly; let it cool down somewhat, mix the spirits of turpentine little by little with it, and at last the alcohol in the same way. Should the alcohol be added while the mass is too hot, much will be lost by rapid evaporation; if, on the contrary, it is too cool, it will form a viscid lump and must be slightly heated again. Stirring briskly is indispensable to mix the ingredients thoroughly. In well-corked bottles it keeps for years. If in course of time it becomes too thick, the addition of some alcohol will make it liquid again. For this purpose it must always be warmed. It is a good plan to put the bottle containing it in boiling water or hot water to accomplish this.

TOMATOES.

(From Hogg's Gardeners' Year-book.)

THE love-apple or tomato (*Lycopersicum esculentum*), is a native of Mexico and South America, but it is also found in the East Indies, where it is supposed to have been introduced by the Spaniards. The Malay name is tamatte, and in Mexico it is called tomatl. The whole plant has a disagreeable, acrid, and nauseous odour; and its juice inspissated over the fire emits a vapour so powerful as to cause vertigo and vomiting. The fruit, which are the only part used as an esculent, are extensively used in Spain, Italy, and France, in soups, sauces, and pickles; and even in their natural state they have an agreeable acid flavour. In our own country the cultivation of love-apples is becoming much greater than formerly, and the more the community becomes acquainted with the many agreeable forms in which the fruit can be prepared the wider will the cultivation be extended. For soups, sauces, ketchup, preserves, and confectionery they are equally applicable, and the unripe fruit makes one of the best of pickles. By analysis the fruit of the love-apple has been found to contain a particular acid, a volatile oil; a brown, very fragrant, extracto-resinous matter; a vegeto-mineral matter; muco-saccharine, some salts, and in all probability an alkaloid. According to the analysis of Fodere and Hecht the tomato was found to contain:—1. A peculiar acid which is destroyed by a distilling heat, and which is combined by a bitter principle, probably solanin. 2. A volatile oil difficult to separate, and which evaporates with great rapidity. 3. An extracto-resinous brown matter, of a pitchy consistency, having a strong smell and a bitter-sweet taste, soluble in water and partly soluble in alcohol and ether. 4. An albuminous matter which readily putrifies. 5. A little mucous sugar detected by the smell of caramel at the commencement of combustion. 6. Sulphate of potash, a little chloride of potassium and calcium, pure potash, and probably a vegetable alkaloid, which resides much more abundantly in the leaves than in the fruit. Professor Church gives the following quantitative analysis of the tomato. Ripe tomatoes contain in 100 parts:—Water, 89·8, albumen, 1·4; sugar, 6·0; malic acid, 0·7; cellulose and pectose, 1·3; mineral matter, 0·8. In 1lb.:—Water, 14oz. 91gr; albumen, 98gr.; sugar, 420gr., malic acid, 49gr.; cellulose and pectose, 19gr.; mineral matter, 56gr. For one part of flesh-formers in tomatoes there are about four parts of heat-givers, reckoned as starch. Few products of the garden have increased so rapidly in popularity as the fruit of the tomato. A few years ago the demand for tomatoes was extremely limited. In many private gardens a few plants trained against walls afforded all the fruit that was required, but now plants are largely grown under glass, and a supply of fruit is expected all the year round. In markets, too, the demand for tomatoes was of the slightest, and where a hundredweight was sold a few years ago, a ton is sold now; indeed it is not unusual for a London fruit salesman to dispose of a ton of tomatoes in a day. Since the tomato has become so popular, and as it is unquestionably wholesome, it would not be inopportune to refer to the various modes of using the fruit.

COLENSES.

IMMENSE improvements have of late been effected in the habit, style of foliage, and the colouring of these. A few years ago the sort known as Verschaffelti was, and had been for long, unrivalled among the dark leaved sorts; now it is not only rivalled, but surpassed, by such kinds as Mrs. George Simpson and Duchess of Edinburgh. A few of the best for small collections, besides the two just named, are Harlequin, Miss Rodina, Magic, and Aurora. The Coleus is one of the easiest of plants to cultivate. It must be grown in heat, being properly a stove plant; but from this time till the end of August, it will do freely and well in a greenhouse. The propagation should be done by cuttings in a hot-bed, the young freely growing shoots being the proper kind of cuttings. Insert them in sand and leaf mould, and place them in moist heat, and they will root in a week. They should then be potted into a mixture of loam and leaf mould, and be grown liberally till they occupy the size of pots they are ultimately intended to fill. If to be grown to large sizes, they should be pinched to induce branching, and must be tied and staked in accordance with the size and shape desired. Keep them, well exposed to light, to induce intense colouring.—*N. B. Agriculturist.*

ON FUCHSIAS.

THE popularity of the fuchsia does not wane as time goes on. Although grown by market florists by the million in this country annually, its graceful style and attractive colours are as much appreciated as if it were newly introduced or a very rare plant. There are a good many species in cultivation all more or less beautiful, but it is the lovely, free flowering varieties of the florists, which have resulted from careful hybridizing and selection, that are the great favourites with the people. The simple culture of this popular plant has no doubt much to do with its hold on the appreciation of the thousands of amateur gardeners who, one and all give it a place in their greenhouses, or, for want of such perfect accommodation, in their windows. It is easily propagated by means of the soft growing points of the branches placed in brisk bottom heat; or in the absence of that, it will do quite well if kept close and moist in a case of any kind in an ordinary

room. If a greenhouse is available, it is no difficult matter to keep up a supply of the fuchsia in flower for eight or nine months in the year. For this purpose the first batch of cuttings should be inserted in January and another and successive batches in February, March, April, and May. When rooted, the plants should be pushed on without check of any kind. Beautiful little plants should be flowered in pots five inches in diameter, but of course, if they are to be grown in larger pots, they must not be allowed to become pot-bound till they are placed in the size they are finally destined to occupy. When a fuchsia begins to flower its tendency to grow becomes less, the processes of growing and flowering cannot be promoted together in the same plant; so that if the plants are intended to be grown to a large size, they must be liberally encouraged by ample pot-room, rich soil, and abundant moisture in both the atmosphere and at the roots. After the pots become well filled with roots it will be necessary to maintain the strength and vigour of the plants with regular supplies of liquid manure. The soil for the fuchsia should be rich and open or porous, so as to admit of the freest percolation of moisture. Rich loam of a very fibrous texture that has been stacked for six or eight months, layer on layer with cow or horse manure, is the best that can be used. It should be chopped up roughly, and not sifted, breaking is rather with the fingers to such a degree of fineness as will suit the size of shifts that is to be given. In growing them in small pots much care has to be given in the matter of watering; but indeed this applies to any size of pot after the roots have fully occupied it, only in small pots the risks are greater if any shortcoming in the supply of moisture occurs.

Staking should be carefully attended to as the plants grow and in varieties that do not naturally branch freely, it will be necessary to stop the leading shoots, so as to induce branching from the base of the plant. The natural form of the fuchsia is somewhat pyramidal, and this is the form in which its pendent inflorescence is best exhibited; so that, without laying down any rigid rule, it may be said to be the best way in which to train the fuchsia.

The list of varieties of fuchsias is now almost endless, but the following are some of the best for free flowering, and especially for window culture. Mrs. Welsh and Mrs. Marshall, with waxy white flowers and deep rosy scarlet corollas. Try me O! and Sedan, La Crinoline, and Daniel Lambert are among the most useful and beautiful of the dark red varieties for window culture. These are all single flowered sorts. Among the more free growing sorts, which are better adapted for greenhouse culture, and for being grown to large size, either for conservatory decoration or for exhibition purposes, some of the older sorts are yet unsurpassed. Avalanche, Sir Colin Campbell, Rose of Castile, Mrs. Bennett, Vanqueur de Puebla Dr. Jephson, Lucy Finnis, Marquis of Bristol, Mrs. Cannwell, Little Bo Peep, and Black Prince are all distinct types, and include the principal characteristics of choice fuchsias. An exceedingly distinct form recently introduced is Lord Beaconsfield, which in habit and foilage is highly excellent. The flowers are inferior in size and in brilliancy of colour to many of the older sorts, but are distinct in form, being more like some of the natural species, such as fuchsia spendens. The oldest white fuchsia, *Venus victrix*, which was introduced, twixt thirty and forty years ago, has recently, after having been lost for many years, re-appeared, and is hailed as an acquisition. It is a diminutive grower with small flowers and foliage.—*N. B. Agriculturist.*

CLEMATISES—THEIR USE AND CULTURE.

THE immense increase in the varieties of this all-popular climber makes selection difficult. Many of the sorts are too much alike in character to be distinct; yet where a large collection can be grown, it is a most difficult thing to reject any of them, all are so good. The only thing one can do with limited space is to select one or two from the several types, when the leading features of the whole group can be brought together in a comparatively small collection. The several types take their names from the species they have been derived from. The chief of these, are .C. Patens, Florida, Lannginosa, Viticella, Jackmanii. There are a few other types less important from an ornamental point of view, but which may be grown for the sake of distinctness where room can be spared for them. Of the Patens type, which are Spring flowers, and best adapted therefore as climbers in the greenhouse or conservatory, two of the best are Stella and Miss Bateman—the latter is pure white, with chocolate coloured anthers; the former is light violet, with a. deep red plum-coloured bar down the centre of each petal. The Florida type furnishes some handsome double-flowered sorts, some of which are also highly fragrant. The Duchess of Edinburgh, Lucie Lemoine, and John Gould Veitch are three of the best—the latter is lavender blue, the two former white. These are particularly valuable for cut flowers, especially for filling vases and other free-and-easy arrangements. The Lannginosa type supplies many splendid varieties. The flowers are usually of enormous size, some, such as Symeiana, being as much as 8 or 9 inches from tip to tip of the petals across the centre of the flowers. They are all-summer flowering sorts, extending in favourable seasons into autumn. Henryi, pure white large flowers; William Kennett, deep lavender; Launginosa nivea, pure white flowers of great substance, one of the best for out-doors blooming; Duke of Norfolk, dark mauve; and Symeiana, delicate lavender blue, are a few of the most distinct of this type.

The Viticella type is a very elegant one, and flowers in the summer and autumn. Viticella rubra grandiflora, with bright claret flowers, is a beautiful and very profuse blooming sort. Lady Bovill has greyish blue flowers and Hendersonii bluish purple flowers. The Jackmanii type is the most profuse flowering of all, and is the best adapted to out-door culture, particularly in cold districts. They are also summer and autumn bloomers. Jackmanii, the typical sort, is a deep brilliant violet purple, and the most profuse bloomer of all; Rubella has rich claret red flowers, also very profuse, Alexandra has pale redish violet flowers, and Velutina purpurea, with deep black mulberry-coloured flowers, is very effective as a contrast with some of the lighter coloured varieties in the other types.

The Clematis thrives in almost any good garden soil, and does tolerably well even in soils which cannot be described as good; but if the natural soil is not good it will pay to make it so. If it is light and sandy, it should be rendered more retentive by incorporating with it a large proportion of good clay or dense loam. In naturally heavy wet soils it is desirable to drain well; and in all cases where planted out it is desirable to mulch with good cow manure over the roots. As regards pruning, the Patens, Florida, and Lannuginosa types require to be pruned by cutting out all weak straggling shoots, retaining only the strongest one-year old branches, from which the flowering shoots proceed. The pruning of these should be done; any time during the latter part of the winter. The Viticella and Jackmanii types should be pruned back freely as soon as they are done flowering, and every weak shoot should be cut out, so as to encourage the formation of the strongest summer growths, on which the flowers are borne.

The Clematis, in almost any of the above sorts, is adapted to the clothing of rookeries, rooteries, stumps of trees, walls and trellises. Those also of the Jackmanii type may be employed with fine effect as bedding plants, or trained over trellises on beds so as to form flat or undulated masses, according to taste. Any of them may also be used as greenhouse climbers with the best effect where such house is unheated, in which case little else will do so well bearing the name of greenhouse climbers. Nothing can equal them for the clothing of arbours and bowers of lattice-work in wood or iron.—*N. B. Agriculturist.*

THE WOOD APPLE.

WOOD apple (*Feronia elephantum*). Hindi, *Kyath* or *Cavitte*; Telugu, *Yalag-Kai*; and Tamil, *Vellam*. This tree is considered by not a few to be useless perhaps, because it grows wild, and is to be found in almost every place especially in the jungles. Hence, I surmise, it has met with only a cursory notice in our Garden Manuals, and is said to be—"not entitled to a place in the garden." To disabuse the minds of some folks I shall here note some of the many purposes to which this tree (that is prettily clustered with fruit) is applied to. I shall commence with its—

(*a*). *Fruit*, when ripe, and after the globular shell is broken, it has a very strong odour. The tartish pulp is *farinaceous* and granular which is eaten with sugar; some make a hot weather beverage of it like the "*mango fool*." A most delicious and palatable jelly is made from the juice of the pulp, and which, if properly made, will gratify all *connoisseurs*. The colour of the jelly is of a lovely ruby, and a better kind could hardly be made from any other Indian fruit. Certainly it cannot be excelled. (Wood Apple and Guava mixed also make a good jelly). Although "Firminger" pronounces the jelly" to be such as it is not likely would be approved of by many," but I beg to differ from this opinion. The *unripe fruit* is made into pickle and "*chutney*." The next is the—

(*b*). *Shell* from which humming tops are made. Rockets are also manufactured from it for making Mr. Stripes uncomfortable in his den. Now I come to the—

(*c*). *Foliage*,—The tender leaves which have a sweet *aroma* are much prized by natives; they use it extensively for curing flatulency.

(*d*). *Timber* containing saccharine matter is much relished by "borers," and renders it useless; but it finds a ready place in the kitchen.

(*e*). The *viscous* juice produced from this useful tree is equal to the gum obtained from the *Babool* (*Acacia arabica*) commonly known as "Gum Arabic." Last though not least, I conclude with its—

(*f*). *Medicinal properties*.—The *unripe* fuit when made into *decoction* acts like an *astringent*. The *ripe* fruit is an *antiscorbutic*, its effect being much similar to the *Bael* (*Ægle marmelos*.)

After enumerating the above uses of this generally despised *Wood Apple* tree, I fail to see why it should not be entitled to a place in the Indian Garden Manuals.

* * * * * *

The *Feronia* belongs to the *Aurantiaceæ* or orange tribe, as also does the *Ægle Marmelos* or *Bael* of the Punjab. The young fruit of the wood apple is almost a perfect substitute for the *Bael*, and universally procurable throughout India while the *Bael* is not.—*Asian.*

FORESTRY.

THE *Madras Standard* does not approve of the new rules relating to villagers cutting firewood. We are inclined to think that they constitute a hardship, but it is unavoidable, and if not kept in check by some system, these people would cut down every stick in the forests. Our contemporary says:—

Correspondents writing from the Cuddapah district complain of the operation of the new rules with respect to forest products and the cutting of woop for fuel. Under the recent orders of the Government certain forest tracts not only in that district, but in Kurnool and Bellary have been "reserved" and unless persons are provided with passes they will not be allowed to enter a forest and cut wood for fuel. In the villages and hamlets of the districts, hundreds of poor people, who have no other occupation, cut wood for sale and not timber for that would be opposed to the rules of the Forest Department. Each cooly picks up and cuts as much as he or she can carry and there was hitherto no objection to this. But under the new rules it appears that this system of indiscriminate picking and cutting of wood for sale, is to be put down, and unless passes are granted to wood sellers, they will not be permitted to enter any "reserved" forest. The new rule may have been introduced with the approval of the Government. But we consider it very hard that the poor people in the villages, who can hardly gather more than four annas' worth of wood every day in the forests and by the sale of which they eke out an existence, should not be permitted to enjoy an advantage which they have been allowed from time immemorial. Hundreds of people in the villages get their living by cutting and selling firewood, and the practice prevails in the suburbs of Madras where no forest rules have been introduced, and where fuel is collected without let or hindrance. It may be that this rule applies to only certain forests and not to others. But no harm can be done to any Government forest or plantation where people are permitted to carry away only head loads of firewood. A large quantity of this wood is picked up from the forests, and there can be no deterioration or damage done if the old system were continued. It is these new rules and regulations that make the administration unpopular and induce the people—even the poorer classes—to sigh for the good old days.

EFFECTS OF THE WINTER'S FROST ON TREES AND SHRUBS IN THE EAST OF BERWICKSHIRE.

MR. C. STUART, M.D., Hillside Cottage, Chirnside, writes:—Now that the country is beginning to assume the appearance of spring, the blasted appearance of the woods must strike every observer. The Scotch firs, spruces, and silver firs are browned, especially on their sides exposed to the weather, to an extent never remembered by the oldest men; and what with the withered vegetation on the hedge banks, the complete destruction of the hardy whin, and, until within the last few days, the absence of all green to relieve the eye, the country presents a sombre aspect quite unusual at this season. Except in sheltered nooks, the common primrose is not generally in flower; and the king cups are only just opening. In low lying situations, where the temperature was many degrees below zero, the oaks are killed outright. For three years in succession it has been observed that large limbs of these trees were in a dead condition. But it was only last year that a few watery shoots, with enlarged leaves, showed to what an extent some of them had been damaged. The past winter seems to have finished many of these. Last week I visited a place on the Teviot, where the temperature closely resembled our low readings of the thermometer in Berwickshire. Several of the oaks were completely dead; a few whip-like shoots from the trunk constituted all the growth made last year. These shoots are now entirely killed by last winter's frost. Great sheets of bark, completely decayed, were falling from one of these trees on the lawn, plainly indicating that the tree was entirely dead. Two very old Spanish chesnuts were also killed, and all the tenderer shrubs, fruit trees, and conifers. In low-lying situations, especially in the course of the rivers Blackadder and Whitadder in Berwickshire, a similar destruction among trees, shrubs, &c., has taken place. 198 dead or fatally damaged fruit trees were dug up out of one garden, while not a holly remains alive on the same estate. Beautiful specimens of the rarer conifers, planted with great judgment and taste, are either killed outright or fatally damaged; while the fine old ivy that festooned many of the older trees is lifeless. Many years must elapse before the effects of the weather on vegetation for the last three seasons can be rectified. Owing to the wetness of the first of those years, the woods never ripened. In consequence, it was ill prepared to endure the extreme temperatures it was subjected to. When the frost was most severe, the trees were heard to rend both in their trunks and branches from the expansion of the moisture they contained. This was heard both in Northumberland and Berwickshire by credible witnesses, who can point out the trees, principally limes and elms. These persons describe the sounds heard as most peculiar, something like a sharp report. A very painful lesson has been given to all persons engaged in beautifying their policies with the tenderer shrubs, who will, I should suppose, be very chary in future in planting any but the hardiest varieties, especially in low situations, with the prospect of other Arctic winters.—*Scotsman.*

TEA.

THE *Pioneer* noting Mr. Wood-Mason's visit to Assam to investigate the nature of those insect pests which are so destructive to tea, says:—

Mr. Wood-Mason finds that the tea-bug is armed with a serrated ovipositor, in appearance, as in sharpness, resembling a sword, with this the insect pierces the leaves of the plant, and deposits therein the eggs that eventually cause such villainous mischief. But the most important discovery is that the pest appears invariably to choose the blighted portions of bushes for these operations, and thus there is good hope that by vigorous and unremitting plucking of these parts the evil may be mitigated.

Perhaps a more sensible plan would be to remove the cause of those blighted "portions of bushes" by more generous treatment by way of cultivation and manuring.

THE PROPOSED TEA WAREHOUSE.

THE following letter from an Old Planter in this district to the Secretary to the Port Commissioners of Calcutta on the subject of the new Tea Warehouse, which they propose to build on the river bank at Armenian Ghât, seems to shew that in spite of the disfavour with which the Editor of the *Indian Tea Gazette* regards the project, the only real objection to the scheme lies in the extreme probability, amounting in fact almost to a certainty, of its creating a monopoly. Reasonably enough planters will look forward, not without some distrust, to the possibility of circumstances arising in the future, under which even the Port Commissioners, who probably are not quite free from all suspicion of our common human weaknesses, might be led to take undue advantage of the powerful position they would occupy. But if this natural distrust can be properly allayed, it really seems to us that the very low rates for shipping and insuring, as compared with those fearsome "Calcutta Agency charges" we all hear so much about, ought of themselves almost to form a sufficiently strong recommendation to ensure the successful introduction of the scheme and its immediate adoption for shipping and insuring their teas by "*planters who are free to do so.*" This last expression is such a very pregnant and significant one, that it will well bear italicising, though it is not so in our correspondent's letter.

22nd April 1881.

TO THE SECRETARY TO THE PORT COMMISSIONERS, CALCUTTA.

DEAR SIR,—In the last issue of the *Indian Tea Gazette* is published a circular from your office, said to have been addressed to those interested relative to a tea warehouse, which it is proposed to establish in Calcutta —and with it a scale of charges, from which I note that on "teas for direct shipment," the following rates are to be levied, viz:—

Receiving and storing	¼	*anna per chest.*
Shipping	1	"
Rent per week on teas kept in the warehouse ...	⅛	"

no rent being charged on "teas sent direct to jetty shed for shipment."

I would beg the favor of your letting me know whether the 1 anna per chest for shipping will also include taking out the insurance policy, and posting it along with the factory invoice and Bill of Lading to the consignee, or the making over of these papers to a bank or others address in Calcutta, as the case may be. All that has to be done of course, is to send a peon first to the Insurance Office, and afterwards to the Post Office, or address given in Calcutta, but for these trivial services there are agents, who demand a percentage on the amount insured, a heavy imposition of course, but there are also circumstances under which there is no option, and so it has to be borne. Though agents less hard and exacting are sometimes found, who are willing to ship and insure under the more reasonable arrangement of so much per chest, their rates are arbitrary and somewhat unreliable, and they cover a wide range, some charging four, others six, eight, and twelve annas per chest.

If the Port Commissioners are able to undertake the business at 1¼ anna per chest, it will be a great step gained in reducing the charges which press so heavily upon tea, and no doubt the saving will induce most of the planters, who are free to do so, to ship their produce through the new agency, if they can only be made to feel reasonably safe against any abuse in the future of the monopoly, which seems likely to be created, if the proposed arrangements are carried out.

Hoping for the interest of all concerned to be favoured with an early and definite reply to the point of my inquiry,—I remain, Yours faithfully,

Darjeeling News.

THE TRADE WITH CHINA IN SPURIOUS TEA.

SOME correspondence has recently passed between Messrs. Joseph Tetley & Co., a large wholesale firm of tea dealers, and the Commissioners of her Majesty's Customs, with respect to a lot of 400 boxes of so-called Congou tea which had been bought by them from the importers, who had sold it on the assumption that it would be passed by the Customs' inspectors. Unfortunately for both seller and buyer, but fortunately for the consumer, the "tea" was "condemned" as not up to the mark. Messrs. Tetley & Co., complain that "thousands of boxes of identically the same tea had previously been sold and passed"—and affirm that the Act to prevent impure tea being imported is constantly evaded, owing to the system of allowing the inspectors the discretion of saying what teas shall be passed and what be analysed.

The authorities of the Custom-house, in their reply say:—"With reference to your statement that a large quantity of similar tea had been previously passed, I am desired to acquaint you that the Commissioners will cause inquiries to be made as to the diversity of practice stated to exist among the inspectors of tea, with a view, if necessary of adopting measures to ensure greater uniformity."

To this Messrs. Tetley & Co., in another communication says:—"We were not solicitous to have your decision reversed in the case of the condemned boxes ex *Glengyle*, but to point out to you that identically the same tea as was then condemned as unfit for consumption had previously been passed as pure.

"It is this great irregularity of the working of the present system, that we are desirous of seeing altered, as being a cause of loss of time and great uncertainty to the trade, and, what is of more importance, rendering the Act of Parliament designed to prevent the importation of impure teas quite of no effect, for so long as there is any doubt about impure teas being condemned, so long will it be worth importers' while to bring them in.

"We would venture to suggest to you that the object of the Act would be perfectly obtained were a sample of each break of tea drawn when warehoused, and sent under proper safeguard to the tea office at the Custom-house, where such samples would be carefully and systematically considered in the first place by a professed and competent tea-taster, whose duty it would be to send all doubtful samples for analysis.

"We beg to submit, if such a course were adopted and the Customs' standard of purity rigorously enforced, that in a very short time your analyst would have but a minimum of samples to analyse; for directly it was known and felt by tea importers that all teas under a certain line would every one them really be condemned, and not as now a very great proportion of them passed, then they would naturally cease to import such tea.

"We earnestly trust that you will be pleased to adopt some plan by which all tea under the standard may be condemned. We are confident it can be done with ease, and that the trade would be very pleased to see the Act carried out with all strictness."

COFFEE.

ALTHOUGH the coming Ceylon coffee crop may not, says, the *Observer*, be so large as was anticipated in some quarters at the beginning of the year, still there seems no reason to reduce the estimate of the total outturn between 1st October 1881, and 30th September 1882, below 753,000 to 800,000 cwts. (37,500 to 40,000 tons), against not more than 22,000 to 25,000 tons this season, and with a decease in the Brazil reports and reduction in stocks prices should improve by the end of this year.

ACCORDING to the Batavian *Journal of Agriculture*, the production of coffee by the whole world, in 1855, was 330,152 tons, and in

1878, no less than 490,843 tons, showing an increase during the 23 years of 160,675 tons. These quantities were yielded by the following countries :—

	1855.	1878.
Brazil ...	163,400 tons.	... 225,500 tons.
Dutch Indies ...	71,322 „	... 91,405 „
West Indies ...	29,300 „	... 41,800 „
British India and Ceylon	26,780 „	... 53,422 „
South Africa ...	22,315 „	... 35,890 „
Arabia	6,176 „	... 2,779 „
Africa	4,000 „	... 4,000 „
Central America ...	3,500 „	... 32,500 „

	330,152	490,843

COFFEE.

ALL the species of coffee more or less valuable for economic or commercial purposes appear to be confined to Africa or are of African origin. Of these, one species, *Coffea Arabica* L., the original species of the genus and the one from which all the coffee of the various coffee-growing countries of the world is produced, is believed to be indigenous to the mountainous regions at the extreme south-west point of Abyssinia, the word coffee, it is alleged, being derived from Caffa, the name of one of the provinces of that country.

From Abyssinia the coffee was introduced into Arabia and cultivated in Yemen or Arabia Felix, and for upwards of two centuries Arabia supplied all the coffee then used. Towards the end of the seventeenth century it was distributed eastward by the Dutch, and it is now extensively cultivated in most of the tropical countries of the East.

The credit of introducing the coffee plant into the Western Hemisphere is a disputed point. One story asserts [illegible] the French introduced it into Martinique in 1717 ; while, on the [illegible], the Dutch are said to have previously taken it to Surinam. In either case it is certain that we are indebted to the progeny of a single plant for all the coffee now grown in Brazil and the West Indies.

The writer on the article on coffee in the "Encyclopædia Britannica" gives the following concise summary of the early spread of coffee cultivation :—

"Down to 1690 the only source of coffee supply was Arabia, but in that year, Governor-General Van Hoorne, of the Dutch East Indies, received a few coffee seeds by traders who plied between the Arabian Gulf and Java. These seeds he planted in a garden at Batavia, where they grew and flourished so abundantly that the culture on an extended scale, was immediately commenced in Java. One of the first plants grown in that island was sent to Holland as a present to the Governor of the Dutch East India Company. It was planted in the Botanic Garden at Amsterdam, and young plants grown from its seeds were sent to Surinam, where the cultivation was established in 1718. Ten years later the plant was introduced to the West Indian Islands, and gradually the culture extended throughout the New World, till now the progeny of the single plant sent from Java to Holland produces more coffee than is grown by all the other plants in the world."

Lunan ("Hortus Jamaicensis," vol. I., p. 2[illegible]) relates that the first coffee plants were introduced into Jamaica in the year 1728 by Sir Nicholas Lawes, Governor of the island, and that they were planted at Townwell Estate, now Temple Hall Estate, Liguanea (St. Andrew. In a foot note to this Lunan adds, " it has been asserted that seven berries" only were brought to this island from St. Domingo, and that the owner of the tree, raised from one of them in Vero, sold its first produce at a bit a berry."

"In the year 1732, coffee was cultivated in this island under the encouragement of an Act. 5th George II., by which the duty was reduced on home consumption from two shillings to eighteen pence per pound. By a further reduction of the duty in 1783 to sixpence, the cultivation was very much extended and produced considerably more to the revenue than the former heavy one."

Bryan Edwards ("History of the West Indies." vol. II., p. 801) states that before 1788 the export of coffee from Jamaica was under 5,000 cwts per annum ; after this it soon rose to 27,000 cwts, and a Committee of the House of Assembly in 1792 reported the existence of 607 coffee estates in the Island employing 21,011 negroes.

Coffee cultivation seemed to have reached its maximum in Jamaica in the year 1805-6 when nearly 260,000 cwts were exported. After this, owing to the abolition of the slave trade and slavery, and the consequent abandonment of numerous estates, the exports greatly declined, till in 1866 they reached only 40,400 cwts. Between 1869 and 1874 the total exports have, however, risen from 45,000 cwts to 92,000 cwts, and during the year 1878-79 they were 96,715 cwts.

The ordinary, or Arabian coffee as it is now called, is essentially suitable for cultivation in hilly and mountainous districts, and it is only under the climate conditions combined with suitable soil, aspect, &c., of such districts the most desirable qualities of the "fragrant" bean are produced.

The Liberian coffee, on the other hand, appears to be indigenous to the plains and forests of Western Tropical Africa, and to "grow equally well in the immediate neighbourhood of the sea and at considerable distances from it. It is to this fact that the Liberian coffee owes its importance at the present time as an economic plant of great value, and should its robust habit and prolific character be maintained in other areas its systematic cultivation promises to become one of the most successful of tropical enterprises, "and this, too, it must be remembered, at elevations too low and temperature too high for the profitable growth of the ordinary Arabian coffee."—*Journal of Applied Science.*

CINCHONA.

WE learn that after a lengthened inquiry extending our some years, the Government of Madras has finally come to the conclusion that Indian prepared cinchona, is a really valuable febrifuge, and it will be largely used in the Government hospitals and dispensaries in that presidency, in future, as a substitute for quinine.

THE VALUE OF CINCHONA.

SEVERAL times already we have quoted Mr. Morris' official reports on the growth of cinchona in Jamaica, as affording useful hints to Ceylon planters on the relative merits of the several varieties, and also as to the best means of preparing the bark for shipment, and in his annual report on Government Plantation which by-the-bye has been issued with commendable promptitude, we have some further interesting information on several important points.

In previous notices we have given particulars of four consignments of the produce of these plantations, last year for the London market, but the results have never before been analysed in the form now adopted by Mr. Morris, and they are worthy of careful consideration by all practical men. There were in all 27,299 lbs. of bark, bringing a net return of £5,145. This was obtained from 8,246 trees of all kinds, from 8 to 10 and 12 years old, showing an average yield of 3¼lbs. per tree, or a money value of 12s. 1½d., of the 8,246 trees, 210 were of the hybrid variety, which yielded an average of 4½ lbs of dry bark per tree, or a value for each tree of £1 4s 2d Of the remainder, 3,945 trees were the crown bark, *C. officinalis*, yielding an average of 1¼ lb. of dry bark per tree, and a value of 9s 8½d. Again, 4,091 were red bark trees, *C. succirubra*, yielding an average of 4¾lbs. of dry bark per tree, with an average value of 16s 1d. per tree.

At first sight one is inclined to be rather surprised at the relative returns of the three sorts here shown : but Mr. Morris proceeds to explain away the difficulty as follows :—'Taking the above average values it would appear that tree by tree, the hybrid variety was the most valuable of all, but taking into consideration the small number of trees barked, 210, and the fact that they were exceptionally fine specimens, the comparison of these with the 3,945 trees of crown bark of all sizes, is not quite a fair test —also with the red bark, the average value of these trees at 16s. 1d. compares most favourably with the crown bark trees at 9s. 8½d. Here again it must be remembered that the red bark trees can not be planted so closely as the crown bark, and they take several years longer—probably twice as long—in arriving at maturity ; and on our highest ridges where the crown bark is completely naturalised, it attains maturity in five to seven years, whereas the red bark, suitable only for lower elevations, would require from 10 to 12 years.

Mr. Morris however still maintains, as he has always done that it is most advantageous to grow the crown variety, because as he says the red bark would be certain to feel first, and most severely any fall in the market, as it is not the best for the quinine makers, and is in fact chiefly bought by the druggists amongst whom the demand is of course comparatively limited. Now, however, that the lower alkaloids are finding favour almost equal to quinine, *succirubra* ceases to be a druggist's bark, and will probably be found more profitable in certain localities than the other varieties. The following calculations as to the cost of producing crown bark and the return it would give to the cultivator is interesting, although we are afraid that it is seldom realised in practice :—

"Taking the actual returns of the crown bark as mentioned above, and assuming that they were planted at elevations 5,500 to 6,300 feet, and at distances of 6 feet by 6 feet, or at the rate of 1,210 per acre, an acre of this species would give a gross return of £563. From the working expenses of the Government Cinchona Plantations, it may be safely assumed that an acre of cinchona trees could be established, including purchase of land and all expenses up to the third year, for £30, or up to the sixth or seventh year, when the bark would probably be ripe, about £49 per acre. The cost of barking, curing, shipping, and brokerage has hitherto averaged, about 8*d*. per lb. This would make a total cost of about £100 to grow and put in the market 1,815lbs.—the produce of an acre—of dry bark realising £563."

The report mentions the yield of a single tree on the Government plantation, which is certainly something extraordinary, and we shall be glad to hear if any of our up-country friends can match it in their experience :—"One of the largest trees on the plantations was up-rooted and barked on the 7th of April last. It yieled 40lbs. of trunk bark, 5lbs. of twig bark, and 9lbs. of root bark, equal in all to 54 lbs. of green bark. This when thoroughly dried was reduced to a total of 16lbs. At the average price obtained for this kind—the hybrid variety—viz [illegible] 1s 3¼. per lb. the produce of this one tree was worth £1 [illegible] 4*d*. It may be added that this tree was growing in a sheltered situation in good soil, and was nearly 12 years old. It measured 40 feet in height and a circumference at the base of about 30 inches."

The obvious tendency of Mr. Morris' report on the [illegible] by the Government of Jamaica, is to stimulate the cultivation [illegible] by private enterprise, but he does not overlook the [illegible] then naturally suggests itself, will not the increased supply [illegible] affect the commercial value of the article, and thus render production unremunerative. He is decidedly of opinion that planters need not be deterred by apprehension of this kind. He argues that the demand for quinine is so extensive, and the terrible death roll among all nations of the world from fevers, for which quinine is the sole remedy, is so vast that there is no prospect whatever, at present of the price of quinine being seriously reduced.

On the other hand, the prices of good quinine-yielding barks have been steadily rising. Again when we consider the comparatively small areas in which all the conditions necessary to the production of the best qualities of cinchona bark obtain, we shall find that very few tropical countries can enter successfully upon the cultivation ; and of these possibly only two or three will possess in so eminent a degree all the favourable conditions enjoyed by Jamaica. What is absolutely necessary is to select suitable sites where the plants will enjoy the requisite climate, shelter and soil ; to cultivate only the more valuable and quick growing species, and to establish plantations on systematic and scientific principles, whereby the utmost value is obtained for the outlay, and the conditions of growth carefully studied.—*Ceylon Times.*

GOVERNMENT AND THE CINCHONA INDUSTRY.

From G. King, Esq., M.B., Superintendent, Royal Botanic Garden, Calcutta, and in charge of Cinchona Cultivation in Bengal, to the Secretary to the Government of Bengal, Financial Department, No. 420, dated Howrah, the 30th May 1881.

SOME unfavorable remarks having lately been made in Indian newspapers as to the competition of the Government of India in the London markets with private growers of cinchona bark, I was induced to go into the matter, and it may not be out of place if I lay the results of my inquiry before Government.

2. The tone of the remarks referred to would lead the public to believe that the quantity of bark sold by the Government of India during [illegible] formed so large a proportion of the total of Indian-grown bark as, to a perceptible degree, to influence the market to the detriment of private growers. This view is hardly borne out by statistics. From the circulars of two London firms of bark brokers, I find that the total importations of cinchona bark into England during 1880 consisted of 76,074 packages. Of these, 57,560 were from South America, 483 were from Jamaica, and 18,031 were from India and Ceylon. The 18,031 packages from India and Ceylon consisted for the most part of red and crown bark, there being only 207 packages of yellow, and of these 207, all but one came from the Sikkim Plantation, while the odd *one* came from the Government Plantation on the Nilgiris. The yellow bark sent by the Government of India came into competition, therefore, with no yellow bark grown in India or Ceylon, the fact being that in no plantation in India or Ceylon, except in the Government one in Sikkim, do more than a few yellow bark trees exist. Of 17,824 packages of India and Ceylon-grown red and crown barks sold in London, 1,174 were offered by the Government of Madras. The rest belonged to private growers. Madras Government bark, therefore, came into competition with privately grown Indian bark to the extent of 6·6 per cent.; and of the total bark imported into England, Madras, and Sikkim bark together (1,380 packages) formed a proportion of about 1·82 per cent. These calculations are of packages, as I do not know the exact weights in pounds; but bark packages are always pretty much about the same weight, and the results may be taken as substantially reliable. I hardly think these figures bear out the charge, so lightly brought against the Government, of having damaged the interests of private growers by flooding the market with bark grown with public money.

3. For many years prior to 1880, no bark had been sold from the Sikkim Plantation, the policy of that plantation having from the beginning been to grow bark for manufacture into a cheap febrifuge for the people of the country—a policy which has been consistently and successfully carried out. The 206 packages sent to London last year consisted of a kind of bark which could not be manufactured into febrifuge, and of which, except by sale, there was no means of disposing. A further exportation of similar bark has been made during the present year for a similar reason: but changes about to be introduced into the factory make it unlikely that it will be necessary to send any more bark to London for sale. As regards the produce of the Nilgiri Plantation, the policy of the Madras Government has all along been to sell it in the best market.

4. The figures I have just quoted show that it would be hopeless, even if it were good policy for Government to try to lower the price of quinine for the people of India by lowering it in the home market because that really means lowering it for the whole world by flooding the European markets with bark of its own growing. The direct and simple way of carrying out its avowed object in maintaining cinchona plantations is, as it appears to me, for Government to manufacture the produce of these plantations for use exclusively in India. In its plantations, Government has the means of supplying itself with bark, and with the manufactured products of bark, at a greatly cheaper rate than it could buy them in the open market. In proof of this, I need only say that, on the Sikkim Plantation, bark is produced at a cost price of about 2¾ annas per pound, and cinchona febrifuge at 9½ rupees per pound; while bark of similar quality fetches in London prices varying from two pence (for shavings) to eight shillings and four pence for good quill, and quinetum (which is cinchona febrifuge under another name) cannot at present be bought under forty shillings per pound.

THE PROSPECTS OF CINCHONA PLANTATIONS.

ALTHOUGH the profit of cinchona plantations is said to be from 70 to 80 per cent., cinchona growers in Ceylon and the East Indies will need to look closely into the cost and possible profit of their plantations, since they may soon have to compete, not only with the Government [illegible], but with enterprise in Bolivia. In 1878, a few [illegible] tried the experiment in that country of cultivating the [illegible] and now according to the report of the Dutch Consul, [illegible] on the banks of the Mapiri at La Paz four or five hundred thousand young trees of two years' growth. In other places also new plantations are springing up, chiefly on the mountain slopes which are cultivated for three-fourths of their height. The cultivation of the cinchona in its original home is, of course, easy, the chief danger being from drought or ants during the first two years, and the only labour necessary is to keep the young plants free from weeds during the same time. To give shade to the seedling plants, bananas are planted between them. Already excellent yellow bark from Bolivia has been sold in this country and cultivated South American red bark yielding 3 per cent. of sulphate of quinine, has lately appeared in the London market. At the drug sales this month large quantities of the bark known as "China cuprea" have again been offered, and with it some bark closely resembling it in external appearance, but not containing quinine. Several other parcels of bark have also been offered which do not appear to contain quinine, and probably do not belong to the cinchona genus at all. The variety of gum which gives a ropy mucilage in appearance like white of egg, is still to be met with in commerce. It may interest those who have it in stock to know that it may be restored from its allotropic to its natural condition by dissolving it in hot water, and allowing it to stand for twelve hours or so in a warm place. In appearance the gum is hardly to be distinguished from the best "Turkey" sort, but is of a greyish, rather than a yellowish-white tint.—*Pharmaceutical Journal.*

CALISAYA LEDGERIANA FLOURISHING IN MASKELIYA.

NOTHING will give us greater pleasure, than to be placed in a position to assure Mr. Moens (and the cinchona planting world generally) that whatever may be the case in Java, "a long dry season" is not required in Ceylon to enable the precious *Ledgerianas* to blossom and seed, any more than to grow luxuriantly. And a few more facts added to those furnished in the interesting statement made by Mr. Christie of Maskeliya, ought to convince even Mr. Moens of the fitness of certain portions of our younger districts between Adam's Peak and Great Western for the cultivation of this valuable species. After all, although blossom is an important matter, it is not *the most* important in respect of cinchona. If the *Ledgeriana* trees grow vigorously and put on bark after the fashion of the *succirubra*, species (as stated by Mr. Christie) certainly the cultivation should be pronounced a decided success. His comparisons speak for themselves, and we trust these will be followed by others made by the possessors of *Ledgeriana calisayas* of an appreciable age in Boltumbe or West Haputale, in Madulsima, Maturata, and other districts. The piece of bark sent to us by Mr. Christie, requires no microscope to discover its quality; to break it and taste it is almost sufficient! The analysis shews that Ceylon *Ledgerianas* of the true type are not likely to be a bit behind those of Java in their value to the manufacturers of quinine. Mr. Howard will be greatly interested in the experience of Mr. Christie (whom we heartily congratulate), and we shall forward to the veteran Quinologist the piece of bark sent to us, to enable him to judge of the result even at this early stage.—*Ceylon Observer.*

STATISTICS.

STATISTICAL PROGRESS.

IN due time we shall know the results of the census. The Board of Trade returns show us what change has been effected in other matters of national importance and consideration during ten years. We find that public wealth has increased 30 per cent., commerce 13 per cent., textile manufactures 16 per cent., minerals 45 per cent. The deposits in the Bank of England increased from 23 millions to 39½ millions. The Savings Bank deposits of the working classes rose from 51 to 76 millions. Income-tax returns showed an average increase of £4 per head of the population and even Ireland showed an increase of £2 a head. We heard much about commercial depression during 1879, and yet during that year the minerals raised in this country amounted to 64 millions, as against 41 millions in 1869. As a natural result of these figures, railway traffic grew in very similar ratio, *viz.*, from 41 millions to 59½ millions. The Post Office showed the greatest growth of all *viz.*, from 817 million letters in 1869 to 1,239 millions in 1879. Again, pauper statistics showed a reduction of pauperism by 19 per cent. (*viz.*, from 1,281,000 to 1,037,000), an almost natural corollary of the above recorded increase in national prosperity. Turning from commerce to morals and minds, we find that crime had diminished during the decade referred to. The number of convictions fell from 14,340 to 12,526. On the other hand, intellectual attainments showed development—the natural result of the Education Act. The average attendance of children at school had risen from 1,333,000 to 2,980,000—an increase far in excess of the ratio of increase of juvenile population. Agricultural returns for the same dates were highly significant as showing the gradual tendency for grazing and dairy farming to take the place of cereal production—the inevitable result of the competition of the foreign grain market. The arable land had fallen from seventeen million acres to a trifle over 15½ millions; and in Ireland the diminution in this respect was nearly double in proportion to the arable acreage. As set-off against this, live stock has increased in number, with the exception of sheep. Cows had gone up 8 per cent., horses 12 per cent.; pigs 6 per cent., sheep had gone down 6 per cent.—*Ladies' Journal.*

SERICULTURE.

SILK.

AMONG the wares which farmers in the south of Europe bring to market are bunches of mulberry leaves. They are purchased by people who keep silkworms, and who have not the means on their own ground for feeding them. The leaves are sold by weight in the market, and to select what will nourish the worms best is a task of some difficulty. The farmer wants to sell the heaviest, but the purchaser knows that as the trees grow older the leaf gets smaller, and that it is the small leaf which contains most food. Those who do not buy in the markets, hire mulberry trees in nurseries and plantations for the season—a good tree giving from thirty to sixty pounds of leaves. The price of a tree varies according to the local demand for it, but eight francs would not be considered too much for one yielding thirty pounds of leaves.

When the leaves are carried home from market the rearing of the silk-worm commences. It is a work requiring the greatest care and delicacy, and there are various ways of setting about it. In spite of improved methods, many of the silk cultivators of the south still maintain the most primitive. They have the eggs of last year's grey moths preserved in phials hermetically sealed. These have been immured in earthen pots, kept at a low temperature, so as to avoid premature hatching. To hatch the eggs, they are taken out, and one or two ounces of them being poured into a silk bag, it is worn on the chest for some days. At night it is put under a pillow, or wrapped in fine linen, and the eggs are placed on a bed kept at the average heat of the human body. After the worms are hatched, they are lifted into flat baskets and covered with mulberry leaves, which they devour greedily. The feeding goes on for a week, or it may be a fortnight, the worms not seeking to escape from the baskets where they are supplied. At the end of that time they stop feeding, crawl uneasily among the chopped leaves, and the cultivator knows that they are preparing to spin. At that stage small bushes are given to them—broom bushes, heath, or clean bean-stalks. These are arranged in rows, with air and space between, each, and look like so many miniature hedges. Inside and around them the cocoon is spun. By and by, with the worms inside, the cocoons are carried out to a cauldron in the cultivator's garden and thrown into hot water. The silk then loosens itself, and may be reeled off, and the dead bodies of the worms are given to the birds, who appreciate them as if they were seed. The silk-thread may then go to market and from that to the factory.

The silk-worm is not, however, a native of Southern Europe, though in Spain, France, Italy, Greece, and Turkey its cultivation is pursued with different degree of success. China is the true home of the worm; and it was at Constantinople that two Persian monks, coming from the country of the Seres, first introduced it during the reign of Justinian. It is to this first progeny, carried from the East in a hollow cane that all the later silkworms of Europe must be referred. It was soon discoverd that, with the introduction of the mulberry, Europe could be made as productive as China. Becoming independent of Oriental supplies, silk was sent out from the Greek Empire, by way of Venice for 6,000 years. The Chinese, however, still maintain their ancient cunning in the cultivation of the insect. They allow no stranger into the secret of their trade, and to England alone they send in a good year as much as £4,600,000 worth of silk. The hanks or "books," as they are called, come into the markets covered with caps made of a single cocoon: and it is one of many processes in connection with the culture and exportation of silk by the Chinese which in Europe is neither practised nor understood.

The industry was carried in the eleventh century to Sicily by Roger I.; and, as he had seized some Athenian weavers, silk was not only grown but manufactured with all the art of the period. From Sicily the industry readily passed into Italy, France, and Spain, though the Venetians and the Genoese had already been importing worms and mulberries on their own account. A curious circumstance in connection with it was that the noblest Venetian families thought they might engage in the trade without loss of dignity. Glass and drugs shared the distinction with silk. Louis XI. probably deserves the credit of introducing silk into France. Tours became a rising town under his patronage. Francis I. promoted the industry in the neighbourhood of Lyons and Avignon. Henry IV. personally interested himself in the subject, and the naturalisation of the insect as far north as Orleans. He was anxious to have it introduced at Paris; and at Fontainebleau mulberry trees were planted in great numbers. At the same time he offered titles of nobility to such Parisians as had sufficient enterprize to establish silk factories. Later on, Louis XIV. is found offering a reward of three livres to the cultivator of every mulberry-tree which should be in a thriving condition three years after it had been planted. The consequence was that Provence, Languedoc, Dauphine, Lyonnois, Gascony, and Saintonge became mulberry plantations.

A bold attempt was made by James I. to render silk culture popular in England. It had long been known that silkworms fed in English houses had gone through the work of spinning and breeding as if they were in a southern climate. It seemed, therefore, to King James that nothing was required but mulberry-trees, so he sent out circular letters to the county authorities of England, inviting those who could to buy sprigs in London at three-farthings a piece, and to plant them without delay. For a time there was much excitement at the prospect of silk being made indigenous. Not very long before, a sumptuary law had been passed for the benefit of a too luxurious middle-class, providing "that whosoever shall wear silk in or upon his or her hat, bonnet, or girdle, scabbard, hose, shoes, or spur-leather, shall be imprisoned during three months, and forfeit ten pounds;" magistrates of corporations and all who ranked above them, being excepted from the operation of the statute. But the failure of the effort made the King turn his attention to Virginia as a more suitable field than England. In 1718 when every scheme on which joint-stock subscriptions could be raised was made the most of, one for the cultivation of silk was put forth. A company leased Chelsea Park for 122 years, and planted 2,000 mulberry trees. Nothing came of it. Seven years later, a scheme which promised to be more remunerative was set on foot for the cultivation of silk in the south of Ireland. The climate of county Cork, it was thought would suit both the plant and the worm, and the cheapness of labour would put the cultivators on terms of equality with competitors in the south of France. The undertaking was supported by many who hoped to improve the condition of a peasantry even then understood to be very badly off. Eighty acres were selected near Michelstown, and 400,000 white mulberry trees were planted. They grew admirably; and nothing, at first, seemed wanting to the success of the experiment. But it was soon found that if labour was cheap and the climate suitable, incurable awkwardness of the Irish labourers unfitted them for the task of rearing the worms and reeling the silk. The company had to transfer its capital and appliances to Malta, where there was some hereditary taste for the work among the poorest classes. If the silkworm cannot be cultivated in England, it has been proved that at least in some of the colonies the conditions are favourable to its growth. Colonial Governments have not been blind to the fact. To encourage the industry the Government of New Zealand offered a percentage on all cocoons prepared for export, but as yet the offer has been attended by no result. Victoria, in its vine district, has already begun to cultivate the silkworm, and its cocoons are favourably known. That there is room for competition may be judged from the value of the silk imports into England for any recent year. Taking 1877 as on the whole, a fair average year, it appears that there were imports in "knubs" and waste to the amount of £827,166; of thrown silk, £108,598; of raw silk, £1,452,045; while silks in various stages of manufacture were valued at £12,681,821. In some seasons these imports are of higher value by several millions. In its raw state, the silk is divided at present among 706 factories, having 842,528 spindles, 12,526 power-looms, employing 44,935 workers.—*St. James's Gazette.*

TOBACCO.

Tobacco in France.—The following table from a recent report shows that the consumption of tobacco in France has been steadily increasing:—

	Population.	Amount consumed. Kilogrammes.	Amount per head. Grammes.	Equal to lbs.
1815	29,250,000	8,981,403	307	·67
1826	31,673,853	11,595,084	366	·80
1831	32,731,256	11,071,088	338	·74
1841	34,018,715	16,461,931	484	[illegible]
1851	35,546,919	19,718 039	555	[illegible]
1864	37,133,424	28,019,803	755	[illegible]
1866	37,807,203	30,627,663	810	1·78
1872	35,844,414	27,031,000	754	1·66
1876	36,643,087	31,188,846	851	1·87

It is estimated that there are 5,500 acres under cacao cultivation in Ceylon at the present time, valued at £300,000. From the quantity of seed sold it is probable that over 25,000 acres will be planted.

TOBACCO CULTIVATION.

The following report upon the tobacco fields at Wangaratta has been forwarded to the Commissioner of Customs by the Chief Inspector of Excise:—

Custom-house, Melbourne,
20th April 1881.

The Hon'ble Commissioner, Trade and Customs.

Sir,—I have the honor to report that I left Melbourne for Wangaratta at 10 minutes past 6 A.M., on the 15th instant. Immediately on arrival I visited the tobacco plantations in the immediate vicinity of the town. There are 85 acres under crop, in the hands of one European and 13 Chinese. They have not yet commenced to cut the tobacco. On the 16th I inspected the plantations on the western side of the King River, and found the greater part of the crops drying in the sheds. The acreage under cultivation had been 123 acres, owned by six Europeans and two Chinese. On the 17th I went five miles further up the King River, being then 50 miles from Wangaratta, and saw six plantations, comprising in all 121 acres, and cultivated by two Europeans and four Chinese. On the 18th I returned to Wangaratta, [illegible] the eastern side of King River, and found that 183 acres had been under cultivation, worked by seven Europeans and four Chinese. The tobacco is in various stages of treatment, some of the leaf having been removed to the drying-sheds some three or four weeks since, whilst in other plantations the tobacco plants have not been touched. All agree, however, in the opinion that the yield this season will be of fair average quality. The total quantity of land cultivated this year in this district is about 511 acres, and is expected to produce 250 tons. There are 25 Europeans and 150 Chinese employed in this industry. From all sides I gather that complete satisfaction would be given to the tobacco growers if the Government would add an additional 6*d.* per lb. on the imported leaf, for, without doubt, the quality of the colonial tobacco is such that the present imported article would be completely shut out of the market, as all, or nearly all, the land on both sides of the Upper King River would be devoted to the culture of tobacco. Drought appears to be the greatest enemy the growers have to contend with, but they say that if sufficiently protected, they could irrigate the land by artificial means, at no considerable cost, as the land borders either upon the river or on creeks running from it. Naturally, if the tobacco could obtain a fair paying price, the grower would exercise more care and attention on the plants as they mature, both under crop and after housing. I may here state that the Chinese, many of whom I found to speak English fluently, and who are exceedingly intelligent, have advantages over the European in their constant supervision and untiring efforts to keep the plants free from insects, &c. From careful observation, I am satisfied that in this district there is no improper manufacture of tobacco, the people are simply growers. I also visited the two breweries and tobacco factory in Wangaratta. Attached is a list of tobacco planters, with the acreage under cultivation.—I have the honour to be Sir, your obedient servant.—*Australasian.*

H. T. HAMMOND,
Chief Inspector of Excise.

CHINESE TOBACCO.

It will no doubt be news to a good many people that Chinese tobacco is being consumed in this country, and probably to a considerable extent. In his last report from Hankow her Majesty's Consul tells us that tobacco has for some years been a favourite speculation in that important trade-mart, and that investment therein is at length becoming profitable now that the uses for which it is best adapted have been recognised by Home manufacturers. The supply is so large from the provinces, of which the mighty Yangtszekiang forms the market-road, and the leaf so fine in colour, texture, and fragrance, that merchant after merchant has [illegible] convinced that it ought to form a profitable export; but, though in [illegible] it was sent to America to aid in the manufacture of Havana [illegible] to England for similar purposes, it has not until quite lately proved a remunerative investment. It is now Mr. Alabaster believes, used for the manufacture of cigarettes, under the name of Turkish tobacco, and for mixing with various cut tobaccos in this country; but he goes so far as to express his conviction that, when better known, it will be smoked on its own merits. Mr. Alabaster, of course, only refers to the unprepared leaf-tobacco, the prepared article from the nature of the process it goes through having a taste somewhat nauseous to the foreign palate. It will be interesting to note, in conclusion, from the last available trade-returns, that in twelve months close upon eight million pounds of this leaf tobacco were exported from Hankow in foreign bottoms alone, without taking into consideration the amount shipped in native junks; the estimated value being given at about 120,000lbs. We have no means of knowing how much of this event beyond Shanghai and the Chinese coast-ports, but we imagine that the bulk of it was not intended for foreign consumption.—*The Colonies and India.*

THE INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL VI.] CALCUTTA :—MONDAY, 1st AUGUST 1881. [No. 8.

NOTICE.

SUBSCRIBERS to the STATESMAN, FRIEND OF INDIA, *and* INDIAN AGRICULTURIST *are informed that arrangements have now been made by which these journals will for the future be published under the general superintendence of the undersigned.*

All communications regarding literary matter should be addressed to the Editor of the paper for which it is intended.

All communications concerning the general business of the STATESMAN AND FRIEND OF INDIA *Office, Advertisements, and Subscriptions to the* daily STATESMAN AND FRIEND OF INDIA, weekly FRIEND OF INDIA AND STATESMAN, *and* INDIAN AGRICULTURIST, *should be addressed to the MANAGER,*

WILLIAM RIACH.

13*th June* 1881.

CONTENTS.

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

DUAL SAP.

TO THE EDITOR.

SIR,—While expressing my thanks for your allowing my article on the "two saps" to appear in your paper, I must admit I was much disappointed at your remarks, for I had hoped to have been shown by yourself where my theory was faulty, or that some of your numerous subscribers would have taken up the subject. To me it appears one of great interest which would revolutionize many existing practices which appear utterly opposed to Nature. I trust you will pardon my writing again, and that you will venture some comments and not treat the subject as you did on previous occasions, it being one that cannot be passed over by alluding to what has and is being done, but what is necessary; and to show clearly the manner in which Nature can be helped, for I conclude man in his pride will allow that this is all that our feable efforts can bring about. But to my subject.

The treatment of coffee is what I will first take up.

While accompanying a friend in charge of a coffee estate on the Neilgherries, I observed him plucking up the young shoots on which there were no flowers; and was told by him that, by so doing the sap which went to their nourishment would tend to increase the size of the berries. This first led me to draw the distinction between the fruit and leaf-sap. It appears to me that as with the human being and animals so with plants; Nature changes its condition at the time for propagating its specie. The same nourishment tends to support blood and milk; yet no one would I suppose be so bold as to say they were synonymous. Good milch cattle will never be found to carry much flesh, hence the inference that the greater portion of nourishment taken is converted into milk instead of blood. Now I hold that with the change of seasons plants always take their turn, and that this period to them is like the seasons for propagation to human life, the same sustenance undergoes a different process by which fruit-sap is created, and so long as it exists, it performs its functions towards supporting the fruit; but so soon as no longer required, ceases to flow as in the case of milk, and changes its nature into leaf-sap as milk does to blood. There could not be a better illustration than the mango tree, of a year when the pollen is destroyed. On examination, the leaves will be found, covered with a coating of sugar-sap ejected from the flower. If Nature could utilize this sap in the support of leaf, is it likely that it would exhaust itself in the manner it does? You remarked that if this theory were correct, what would be the advantage to tea-planters, in their removing the flower of the tea plant? This can easily be shown, the flower being removed which to the plant is like the young to the animal, the necessity for its nourishment ceases, thus the space occupied by the fruit sap is taken up by that of the leaf, and a considerable portion of the time which would be spent in the fruit is devoted to producing leaf.

I have a theory of my own with regard to the cultivation of vine, which I should like much to have discussed.

E. A. C.

Hardoi, 26th June 1881.

ARTIFICIAL INDIGO.

I.

(To the Editor of the Times.)

SIR,—As one interested in the indigo trade, permit me to refer to your report of Professor Roscoe's lecture under the above heading. In acknowledging the great learning and well-known skill which Professor Roscoe is enabled to bring to bear upon any subject in connexion with chemistry, I must, nevertheless, take exception to one or two statements made by him in his lecture as reported by you. My principal objection, and it may as well be stated at once, is that the invention referred to is called the discovery of "artificial indigo," whereas the discovery does not go beyond an attempt to produce indigo blue. Indigo commonly so called contains, besides indigo blue, indigo red, and indigo brown. True indigo blue is considered chemically as the pure article, but the natural dye contains, in addition, the other two substances, the former of which, at least, is certainly a [illegible]t influence in the dyeing processes. What effect, if any, the lat[illegible]y have, has, I believe, never been definitely settled ; b[illegible]question that indigo red modifies this process considerabl[illegible]refore, as the discovery goes no further than the artific[illegible]of indigo blue, I think it can hardly be considered that the [illegible] which chemists have set themselves for the past 40 yea[illegible]solved ; the most that can be said is that another among th[illegible]mpted substitutes for indigo has been brought out. This poi[illegible]eing fully admitted—*viz.*, that the discovery is that of indigo blue alone, I am prepared to allow that the "propiolic" acid, if sold at a moderate price, may be used for many purposes for which indigo is not suitable. Hence the two may well work side by side.

To show that the artificial product is not the same as natural indigo, I may state that I am given to understand on the very best practical authority that the shades of blue produced by indigo cannot be attained by the use of the "propiolic" acid, and further that the great desideratum of natural indigo, perfect fastness, is in a great measure wanting in this artificial production. This alone would condemn its use for many purposes, as "indigo dyed" is almost a synonym for fastness of colour—*i.e.*, inability to fade or wash out. While on this point, I may deplore the present taste or fashion for bright, but fugitive shades. We hear on every hand complaints as to the fading of articles of dress, carpets, &c., and the statements continually made that 20 years ago carpets lasted longer and looked far better after years of wear than they do now after as many months. The reason is obvious. Coal-tar dyes are now used to a surprising extent, and, even where they are supposed not to exist, with the result as given above. The remedy is, however, wholly in the hands of the publicc. Beyond this, even the use of some of these coal-tar dyes is positively poisonous. Many instances have appeared in the public prints as to their baneful, nay, even fatal, results. An instance of this came before my own notice but a short time since. The groom of a neighbour having cut his foot, found shortly afterwards that the foot was poisoned. It was only with the greatest difficulty and after many weeks of illness that amputation was found unnecessary. The cause was found in the colour of the red sock he wore. Scarlet, till within the last two years was rightly considered one of our fastest and safest dyes, and so it is still when the natural dyes, cochineal and lac dye, are either used, but recently an aniline scarlet, more easy of application, has been discovered ; and if the public find that their scarlet flannels no longer stand, they will know where the blame lies.

This invention of artificial indigo blue is derived from coal-tar. That the discovery of artificial indigo will never be accomplished, it would be folly to assert, but at present I think we are some long distance removed from it. I have already shown that the article now produced forms only one component of the natural dye, and according to Professor Roscoe is very costly. Taking his figures of 6*s.* per pound for 25 per cent. of the acid, and that the acid contains only 68·58 of indigo blue, in theory, in every 100 parts of acid, we arrive at a cost of 35*s.* per pound within the merest fraction for pure indigo blue, in theory. Now, as theory usually tells against the theorist, we may take it that in practice the cost would be much greater ; but even at 35*s.* per pound, the cost as against the natural dye stuff at present market rates would be about four times as great and not "twice that of the pure natural colour" only, as given by the lecturer. Again, the planters in India could, if necessary, sell their produce at a very considerable reduction on present quotations, so that unless the artificial dye stuff could be produced at a cost not exceeding 5*s.* or 6*s.* per pound pure, it would be unable to displace so long tried a servant as the natural dye, provided always, even at this low figure, the results turn out in practice in every way as good.

I hope that the scare we experienced about this time last year in the London indigo market through the, to say the least, somewhat exaggerated reports which were then made current with regard to the artificial product, may have one salutary effect—namely, that the indigo growers may see that their position is one not entirely free from danger, and that while they have the time and opportunity, they may endeavour to improve their manufacture and lessen the cost of production ; so that should the unhappy event of the discovery of artificial indigo at a paying price ever be accomplished, they may still be able to beat the artificial product by manufacturing at a lesser cost. That the destruction of indigo planting would be a positive calamity, may be seen from the fact that the annual average production of indigo in India alone exceeds, perhaps, three millions sterling, a loss which to India would be serious, both on account of the destruction of so large a proportion of her exports and the vast interests, both European and native, which it would affect.

I am, Sir, yours faithfully,
E. B. BROOMHALL.

9, Mincing-lane, E. C., June, 4

II.

(To the Editor of the Times.)

SIR,—Mr. Broomhall is incorrect in stating that the discovery of artificial indigo "does not go beyond an attempt to produce indigo blue," for this body has actually been obtained in a chemically pure state from coal-tar. He is also wrong in concluding that indigo red has not been artificially produced, for this product has likewise been prepared from coal-tar. The object of my lecture was to bring forward these facts.

I am, yours faithfully,
HENRY E. ROSCOE.

Owens College, Manchester, June 7.

BAMBOO IN CEYLON.

(To the Editor of the Society of Arts Journal.)

SIR,—In the discussion that took place after the reading of Sir Arthur Phayre's paper on British Burmah, on the 13th May, I see that a quotation I read, bearing on the growth of bamboo, from the *Gardener's Chronicle*, of the 30th of April, is (inadvertently) omitted, referring to the Royal Botanical Gardens at Peradenya, Ceylon. H.J.E., a keen observer, writes :—

"Perhaps the most striking objects in these gardens are the extraordinary clumps of giant bamboo, which exceed anything I have ever seen or heard of. In some of them not less, and probably many more, than 200 *culms* of over 100 feet high are growing, as tightly packed together as possible. Some of the stems must be very nearly, if not quite, a foot in diameter, and the average, eight or nine inches. This splendid bamboo is, I believe, a native of the Malay Peninsula, and is the most remarkable instance of rapid growth I know of, each of these immense stems being formed in a few months."

To lovers of botany, a fine specimen of this bamboo may be seen at the Duke of Northumberland's garden at Sion-house, Chiswicke. I have a stem here from that clump, nearly 70 feet high, the top of which pushed its head through the roof of the conservatory.

THOMAS ROUTLEDGE.

Claxheugh, Sunderland, 30th May 1881.

The Indian Agriculturist.

CALCUTTA, AUGUST 1, 1881.

THE AGRICULTURAL DEPARTMENT.

LORD LYTTON gave us the Afghan war and abolished the Agricultural Department. Lord Ripon has closed the war and reconstituted the Agricultural Department. We use Lord Ripon's name in a representative sense. We do not need to consider how much of the credit of the changes of policy belong to him personally. It does not matter that the withdrawal of our armies from Afghanistan and the revival of the sacrificed department may have been ordered by the Home Government ; it is enough to know that the policy thus embodied is in perfect harmony with the policy indicated by the Viceroy in the speeches which he delivered last year, during the too brief period when India was permitted to hear his voice and to know that the Viceroy was a living soul. He said it was his desire to put an end to wars, and to improve agriculture and the condition of the people. The former has been accomplished ; an important

step is now being taken in the direction of the latter. Peace and agricultural improvement must go hand-in-hand, or peace, in India, becomes a doubtful blessing. If both should be linked in history with Lord Ripon's name, he will be fortunate among Viceroys. Under his predecessor, we had a costly and not an honourable war; agricultural improvement was formally declared a visionary idea, by the abolition of the department, which had, it must be confessed, failed to fulfil the chief end of its existence; the development of our system of internal communications was checked, because all available funds were required for the war; new and exasperating taxation and legislation filled up the cup of bitterness which was put to the lips of the people; and while all those evils flowed directly from the Government, nature, as if to mark the period as the blackest in our annals, added to the sufferings of the people the desolating scourge of famine. Lord Lytton's coming to India might well be cursed by the people as bitterly as Job cursed the day of his birth. It is good fortune in itself merely to succeed such a reign. Difficulties and perplexities are, indeed, a necessary inheritance, but, on the other hand, it is hardly possible for a well-meaning ruler not to act the part of a redresser of grievances, a bringer of relief to the people, a social and political benefactor. The time has not yet come to weigh Lord Ripon's claim to be regarded personally as a benefactor to India; but, as contrasted with those of his predecessor, the policy and the measures which it is his good fortune to be identified with, will certainly be remembered as beneficent. And if he cannot claim the full credit to himself of resuscitating the Agricultural Department—a measure recommended by the Famine Commission and approved by the Home Government—it may at least be assumed that it is a task entirely to his liking, for it belongs, as we have said, to the kind of work which he announced last year that it was his wish to perform.

There could be no better time than the present for re-establishing the Agricultural Department and for organising in it a sufficiently liberal and efficient manner. The abnormal drain on the exchequer has been staunched; we have peace all around us and the promise of peace; generally good harvests have somewhat lightened the perennial pressure of poverty and hunger on the people; the main sources of revenue are yielding normally, if not copiously; and, in short, the present condition of India wears an aspect as like prosperity as can reasonably be looked for with its present population and undeveloped resources. We may look upon the present as a day of grace given us to provide against such threatening evils as over-population, exhaustion of the soil, hopeless indebtedness of the cultivators, and failure of the rains of heaven. In order to do this there can be no doubt that a special agency is desirable and even necessary, and a strong, well-organised, and well-supported Agricultural Department is the agency that is required. Is the Government fully alive to the necessity of making the new Department really efficient? Or, which is the same, or nearly the same thing, has it faced the necessity of making the department an agency for spending State funds freely, while for a number of years its labours must be unremunerative? If organised on niggardly principles, it must be a failure, as was the too much ridiculed Etcetera Department. That Department, it may be said, was never allowed to commence its proper duties. It did much miscellaneous and, no doubt, useful work, but the gigantic task of improving the general condition of agriculture and of the cultivating classes was one with which it was never able to cope. In order that the new Department may undertake the work with a reasonable hope of achieving substantial results, the first essential is, of course, that it must be well manned and organised. It may not be necessary that it should spring at once into existence with a fully equipped establishment and complete ramifications all over the country. Financial considerations may compel the Government to go to work gradually, contenting itself at first, as it seems disposed to do, with the establishment of an imperial office, with subordinate agencies in one or two provinces. But a complete scheme should be at once formulated, and a persistent endeavour made to carry it out in its completeness as speedily as possible. The present Government may only be able to begin the work, but it may at any rate leave to its successor the inheritance of an intelligent and comprehensive plan by which the central Department shall be the heart of an organisation co-extensive with the Indian empire, to it would flow a constant stream of facts from every district in the country, bearing upon the condition of the agricultural community and the work being done by the provincial agencies for its improvement. The Secretary would thus be at all times aware of the peculiar condition and needs of every tract, and would issue instructions or advice to the local officials as to measures suitable for the time and place. He would know what districts it was desirable for him to visit personally from time to time, to see with his own eyes what measures could be wisely adopted, and what results were produced by measures introduced. With such an organisation, and such an official personally responsible, there could be no possibility in the future such a thing as a famine taking the country by surprise. The Agricultural Secretary would have his attention immediately directed to any tract where there seemed to be the least danger of a scarcity. From that moment, he would have his eye upon that tract daily; he would be kept regularly informed regarding the progress of crops, and the probable extent of the failure; he would be also able to find out what was the general condition of the cultivators as to poverty or indebtedness, and what stocks of food the district held in reserve. He would know exactly what facilities existed for importing food into the district; he would be able to calculate the extent of the relief—if any—that would be necessary, and would have schemes of relief-works and plans for facilitating transport of food ready for the issue of orders at the moment when they became necessary. The horrors of real famine can only be mitigated; but if we were always fully prepared to battle with them in the way we have indicated, we have no doubt but that in most cases we should be able to avert utter starvation from the general mass.

It is to be wished, however, that the department may not for a long time to come have to concentrate its energies on the relief of actual famine, and that it may be enabled to work so efficiently on measures for famine prevention as steadily to lessen at once the chances of recurring famines and the difficulties of dealing with them. We have not left ourselves space to discuss in this article the means of preventing famine, and indeed the subject has been so much discussed during the past five years, that we can now do little but reiterate. But one thing which should be constantly urged, and never lost sight of, is that *the* way above all others to ensure us against famine, and to stimulate the people to improve their methods of agriculture, is to cover the country as rapidly as possible with a complete network of intercommunication. We do not gather clearly from the Government Resolution what the functions of the new department are to be in regard to the construction of roads and railways. It must, at any rate, be its duty to advise the construction of roads and light railways wherever those are urgently needed to connect producing districts, and districts especially liable to the failure of crops, with main lines of communication. Model farms are doubtless good, if prudently conducted; experiments for the improvement of seeds, of cattle, and of methods of cultivating are highly desirable; but if these are to be of real and widespread benefit to the people, the means of communication must be extensively increased and improved. No measure will go so far to stimulate the people of a district to improve their methods of agriculture and the quality of their stock and crops, as the running of a good road or a railway through the district. Roads and railways are the most effective educators. Apathy and indolence and blind conservatism disappear before them. Give cheap and easy means of communication and transport, and thus ready access to convenient markets, and the peasantry will soon begin to develop both energy and intelligence in increasing and improving the yield of their soil.

Of vast importance also, and of unequalled importance in some parts of the country, is the introduction of a sufficiently elastic system of collecting the land revenue. There is much to be said in favour of a fixed assessment, paid regularly in money at stated times; but, without some relaxation of the system, it is doubtful if ever the condition of the cultivatio

in some parts of the country can be materially improved. Where the peasantry are steeped in poverty and indebtedness, it may be necessary to have recourse, as a remedial measure, to an assessment fluctuating with the value of their crops, and at the same time to collect the proportion of the value payable to Government or the landlord, at the time when the tenant can bring his crop into the market. This would tend to relieve him from the necessity of borrowing from the *bunnia* at heavy interest, but it may be impossible to deliver those already largely involved without adopting a system of Government advances. We should like to see the Agricultural Department empowered to advance money at reasonable interest to cultivators so as to deliver them from the hands of private money-lenders. Government can borrow money at 4 per cent., and if the department would make advances to cultivators at 5 per cent. simple interest, it would be sufficiently remunerated, and would in time emancipate the ryots of India. Roads, railways, an elastic system of collecting the land revenue, and agricultural banks—these, it seems to us, are the grand remedies for the evils that weigh down the agricultural masses of India.

COTTON IN OOMRAWUTTEE.

AN age ago when Britain was scarce known in the East its factories unestablished—when the Portuguese having converted their forts into bartering houses, their renowned heroic qualities into the traders' and the sensualists' keen lust of avarice, had almost run their race, when the Mahrattas, rising like young lions, were casting off the thraldom of the Mogul Emperors and becoming aggressive in their turn, driving before them lawless bands of Pindaries, Arabs, and Rohillas—the machinery of Mogul conquests and their bane. Forcing these to take refuge in the impregnable strongholds of the Satpuras, and other Central Indian ranges, wonderfully built by a god-like race of herdsmen. Whence it was the wont of these predatory bands to issue, increasing and becoming all-powerful in their triumphant progress of rapine and blood. Devastating cities and plains on all sides, and whole countries of unmatched fertility in the Central Provinces and Independent States, now in wilderness and jungle the paradise of sportsmen; attest to the zeal and completeness with which their work was carried out. The supreme element of terror and depopulation in these hordes, were murderous gangs of thugs and slave-dealers; the former satisfied their own requirements by plunder, and appeased the blood-thirst of their god by wholesale strangulation with the gaily coloured silk handkerchief—remorseless, ruthless, unsparing alike of sex, of age, or of youth—the latter regardless of the male, but very careful of the olive-tinted, round limbed, Brahimin damsel, the little beautiful Mussulman girl; carrying them far away into captivity for concubinage, to perpetuate the lordly Rajput race; careful also of the strong limbed Mahratta Kunbi girl for mineral purposes. These raids, very prevalent in the rich valley of the Berars (bounded on the north by the Satpuras) against which the ruling Mussulman power was at times unable to cope efficiently, and at others in league, caused the population to wall in and fortify each considerable town substantially, while the villages girded themselves in with citadels of earth and sun-dried bricks too strong and high for the scaling ladders and offensive implements of the period.

All through this turbulent time and before the black soil of the Berars was, as it is now, famous for its cotton, and the Moguli town of Oomrawutty, owing to its strength and central position celebrated as its principal mart. Fortified and embattled loopholed walls of great thickness, 25 to 30ft. in height, rising to 40 and 50 about the gates; bastioned and ramped for cannon at points of vantage or weakness, encompassed without a break a city of from 40 to 50 thousand inhabitants, to whom seven gates of enormous strength gave exit and entrance; the folds of whose doors 30ft. in height and 16 in breadth, of solid teak iron-plated studded in iron spikes, a foot in length, supported and arched in by carved Saracenic stone-work of unequalled architecture—remain all but intact to this day, mementoes of the capabilities of the constructors. Over these in the palmy days, no perishing flag in lazy flaps now hid and now displayed the emblem of the conquerors; but high above the arch crest of each then impregnable entrance, supported on iron tridents, hung as in the heavens, in solid gold, silver-plated, the crescents of the true believers. In front of one of these gates called Bhosari, on a wide open plain, overlooked and commanded by the fortification, was brought—from every nook and corner of the Berars, in thousands of carts, in hundreds of thousands of network receptacles—its chief produce for sale. And here congregated merchants from all parts, who transported the staple in unwieldly guarded caravans of pack-bulls and camels, men's backs, and country carts, to weavers who clad the dwellers about Bombay, Poona, and Sattara, the country of Hyderabad and a great part of the Central Provinces. But *Si nous avons* change *tout cela*, with regard to the mode of barter, pressing and transit, although the use of the hand-loom is almost a told tale; yet the descendants of the same people are clad by those of the same weavers, from the same produce through the iron looms of Bombay and Hyderabad, Sholapur, and Nagpur. While Bengal and Manchester, Chinese and Australian, Italian and Japanese mill owners are apt bidders for Oomrawuttys. The soil in which this cotton revels consist of disintegrated unformed rock and clay of a dark brown, almost black colour, adhesive to so great a degree as to afford mortar for most of the houses built of stone and brick in the Berars. The varieties of cotton, processes of cultivation, with the implements in use of ginning and carriage remain in *statu quo*, unchanged as in the days of centuries back. The soil is annually superficially manipulated, and only once in every six or eight years is it deeply turned up, not by an ordinary plough, but with a thick pointed or chisel-shaped iron crowbar. When the rains have slightly saturated the soil, the husbandman looks up his team and his *bukkhur*. The former generally after the pattern of the devoured in *Pharaoh's* dream, and the latter, the instrument he uses in place of a plough. It is formed of a blade of rather stout hoop iron two to three inches wide, a foot and-a-half in length and sharp on one side, this is fixed into a block of wood, so as to leave a space between, with the edge downwards; and by means of a slight pole attached both to the block and the yoke, the bulls drag this over the ground at as leisurely a pace as possible. There is a plough handle at the back of the block for the *bukkhur* boy, used more to ease the bulls, and to unruffle the surface of the field as little as possible, than to press on and so perform the legitimate action prior to sowing. This primitive operation concluded, the soil is ready for the seed. Furrows are now created a foot and-a-half apart and say 2 inches deep, with an iron tipped wooden ploughlet; and the seed, carried in an open bag hanging from the operator's neck, is at the same time dropped by him to the ground through a pierced bamboo tube vertically attached to the contrivance. It only remains now to smoothe over the ground with a toothless harrow, and vegetate for a time in "masterly inactivity." Rain is not much required till after the plants have well germinated, and then good showers two days in the week are necessary till the pods are nearly matured and no rain at all after. The land is kept free of weeds altogether, and the outturn depends second to rain solely on this. The weeding is generally performed by running a miniature *bukkhur* between the rows drawn either by men or a single bull. About the roots of the plants the earth is hand-weeded by boys and women. It is a pretty sight to view a field of growing cotton in the rising sunlight; the even hedges of green a foot in height stretch far away to the horizon, the pearly rain drops glittering like diamonds, pendent to the rich sheen of emerald, and how livid the contrast to the dusky earth on which herds of deer search in vain for their accustomed sustenance. But it is a far more pleasant sight to view the same field two or three months after the hedges have not apparently very much increased in height, they are wider and have attained a deeper hue, it may be that they are bent with the multitude of yellow convolvulus-like flowers, and the wealth of silver grey, the bursting "bols" disclose. The earth is freely dotted with the snowy fibre, and covered with the tender shoots the deer loves, and these are grazing close to the cotton picker's women and children, gaily clad, whose wild Mahratta choruses enliven their light toil, and only cause the deer to raise their heads and listen. But this harmony is too perfect for man not to disturb; he must create discord and slaughter, and to this end is that cart freighted with implements of death and destruction drawing near the band of pickers, and while a mock loading of cotton proceeds, hark a rifle's crack and

the lordliest stag of all lies kicking itself into frigidity! Two others fall, and the rest would easily be deceived were they not does.

Picking is commenced in the latter part of November and continued into January if the season is an early one; if late, to the end of February. All about this country the cotton is allowed to fall on the ground, thus attaching to itself grass, weeds, and leaves, consequently it does not command the enhanced rates of the produce of the Surat, Broach, and Dhollera districts where the cotton is picked off the plants. The cotton pickers do not use baskets, but a fold of their wide *sarez* forms quite a sufficient receptacle. From morning to noon is the work incessant, when a short respite is allowed for meals, then on till evening, when, after having carried the result of the day's labour to the house of the owner; each picker receives the startling remuneration of two annas in full of all demands. The ginning is accomplished with the most primitive appliance and in the simplest manner. Cotton owners do not supply ginning machines, the ginners have to bring those with them. Two old women save up together and purchase one at a cost of from Rs. 2-8 to Rs. 3. It consists of a flat piece of wood about 18 inches long and 6 wide, to the sides of which are nailed erect, two pieces of wood tapering upwards. A thin spindle of iron is bored through and through the top of the sides, underneath which, and almost touching it, is fixed horizontally a stick of wild plum wood about 2 inches in diameter and of the same length. There is a handle on one side attached to the iron spindle, and on the other to the plum wood, which being revolved in opposite directions causes an outward rotation. The women turns the handles with the right, and feed the machines with the left hand; their daily task is 21lbs. of fibre, and they are paid by the weight of seed, one pice for each seer. A portion of the seed is reserved for planting, and the remainder used as food for cattle. When a sufficient quantity of cotton is ginned, it is filled by manual pressure into ginning sacks, 5 feet in height and 2½ in diameter, called *dokras* or *ukkhas*, containing 70 seers or so. The village carts convey four to five of these to the market, and the town bundies ten. Cotton is grown in the Berars in the proportion of two fields of the staple to one of food grains and seeds, and this excess of cultivation in a year of ordinary rainfall of 25 to 30 inches does in no way affect the price of edible grains, which are cheap enough, ranging from 20 to 25 seers of common wheat, and 30 to 40 seers of *jawari* per rupee. From within a radius of 20 to 50 miles on the one side, and 30 to 60 on the other, all cotton grown, except what is retained by the local weavers, is brought to the Oomrawutty mart and finds a ready sale. Many firms in Bombay send up agents in the season, and innumerable natives purchase and press for distant local markets. In former times no regular impost was levied on cotton; but there existed from long custom a lien on it, rigidly exacted on the part of the Temple priests and mendicants. The beggars each day in the season lined the different approaches to the mart, and the priests had their raised dais in the centre. The loud cries of the former were rewarded with minute handsful of cotton from the passing carts; and no sooner were these ranged at site of sale, than offerings of fibre were conscientiously conveyed to the lordly *gurus*. The petty mendicants, of course, carried the proceeds of the charity to their own profit and loss account; but it was far otherwise with the dole to the temple. Eleemosynary corporations were constituted by the rules of which the whole sums of money thus accruing were distributed in alms. Each traveller who presented himself had to be supplied with a regulated subsistence allowance for the day. This primitive and unsophisticated method of levying black-mail passed, however, into a different phase on the establishment of the cotton yard, where all cotton disposed of, is subject to a small municipal tax. A moiety of the sum collected, ranging from Rs. 2,000 to Rs. 3,000, and termed the Dhurrum Fund, is annually divided among priests and mendicants who allot its distribution according to immemorial custom. The other half of the tax is expended by the Municipality on improvements to the cotton yard and its approaches. No first transactions in seed, cotton, or fibre are permitted till the same has been registered in the yard, and the duty paid. This yard is a spacious walled enclosure, out of which four gates lead to the principal factories. It was instituted years ago on the introduction of the Cotton Frauds Act to transactions in cotton in the Berars. In the yard, lengthy and handsome Mangalore tiled sheds have lately been erected for the shelter of buyers and their brokers. There are offices for taxing and registration, and places of business for both European and native merchants, and a large fire-proof godown has been erected for storing purposes. Cotton fibre in the gunny parcels, called *ukkhas* of 140lbs. or thereabouts, pays one anna duty, and seed cotton pays two annas the cartload. The latter since the ginning factory of the Mofussil Company was found too strong in the working, taking in large portions of seed—is alone purchased by professional native ginners called *gujars*, each of whom employ from 40 to 60 gins daily. The arrangements connected with this work are faulty in the extreme. Except the wealthy ginners, who possess walled in yards to their houses where ginning is carried on, the Municipality let out open pieces of ground for this purpose outside the city for the season. The lessees encircle these with a bamboo matting, where both storage and ginning are carried on. The seed cotton is piled in huge heaps high above the matwork, quite open to any person having malicious designs, and fires are frequent. Brokers are licensed by the Municipality beyond whom and the owners, none are allowed under a penalty to transact this business. Those dealing in the fibre, pay Rs. 20, those in seed cotton, Rs. 12 for the season. Cotton arrives in the yard generally during the evening and night, and the carts are ranged in rows from end to end of the yard, with the high *ukkhas* of cotton loaded on them, forming long avenues on each side, down which the merchants and brokers promenade to test the samples with the bulk on the carts. In the morning, as the press agents and merchants arrive, they are met by their brokers with samples; and the price is determined in a most unique manner. For instance, the broker says "Jurrie Ellichpur ka Souda," and clasping the merchant's right hand with his—he covers it with a fancy handkerchief or a piece of his waist cloth, when by some mysterious intercommunication of palms and finger, the secret is out and the cat killed. There is generally very little bargaining, as Reuter has already intimated to all concerned, the day's rate at Bombay and other places; and by about 10 o'clock each morning a pretty general clearance has been effected, though throughout a good season from 400 to 500 cartloads are daily attended to.

The cotton is now taken to the compound of the press for weighment. The office of weigher is hereditary and monopolised by one family, the head of which pays a rather heavy municipal tax. He supplies the different factories and merchants with weighmen and receives all sums paid to this account. In the weighment there is always a large margin left in favour of the buyers to the no small chagrin of the kunbis. The *ukkhas* are then stacked prior to manipulation near the press in flimsy open enclosures of bamboo matwork on pebble packed floors. Considering that at the commencement of the season when the full tide of cotton has not yet set in, and at the latter part when it is on the wane, these lie for days exposed to the weather and other contingencies, it cannot be regarded as a perfect arrangement and stone store houses should be erected. By lifts the bundles are then carried to the upper floor of the press building and opened out in front of the agent or assistant. Each bundle is then beaten with long cane rods to loosen its sides and open it out, and then thrown into a wooden receptacle called the "cradle," which when full, holds the necessary amount that presses into a bale. It is afterwards filled into a long cylindrical shaft with the necessary gunny packing laid out underneath, and after being stamped on by men, receives from above the pressure of a heavy iron column acted on by hydraulic power. This is all that is required to compress it into the desired proportions and is done in a minute. A prong-sided socket now lifts the package and fits it into another open iron press, having apertures above and below, so that the hoop iron may be passed round and round the bale. It is then rolled out, the sides sewn on with gunny, weight marked and ready for transit to any part of the world. Of course the different qualities of cotton are dealt with separately. The standard nett weight of a bale is 392lbs; and this quantity presses into a package, and it is a great object to have all the parcels approaching this weight as near as practicable.

In a good season the presses of Oomrawutty turn out from 40,000,000lbs. to 50,000,000lbs, of cotton in 120,000

to 140,000 bales; and the ordinary day's work for one of Hodgart's double hydraulic presses, is 400 bales or 150,000lbs. to 160,000lbs. The charge for pressing a bale and supplying the necessary packing is from Rs. 3-4 to Rs. 3-12. Wood is used as fuel, babul or tamarind, and is purchased at the rate of Rs. 6 per ton for green and Rs. 12 for dry. The colliery at Worora is unable to supply the coal required by the presses. A railway constructed by the State connects Oomrawutty with the G. I. P. line at Badzara where there is a spinning and weaving mill erected under the auspices of Messrs. Gaddum & Co., now fast falling into decay. Why this should be so when it stands in the centre of a cotton yielding district, is difficult even to conjecture; surely it would be cheaper to work the raw material at its place of growth, than to send the same to Bombay or Nagpur, weave it and bring it back again. But the ways of cotton are mysterious, and we have Manchester as a precedent. There are in the Berars four other marts where presses are established, Khamgaon, Akola, Moortizapur, and Akote; but the cotton turned out is all sold as Oomrawuttys.

WILD SILK IN THE PUNJAB.

We would wish to draw the attention of European capitalists and commercial firms in the silk trade, to the great value of the wild silkworms (and of the silk produced from such cocoons) to be found in the valley of the Sutledge River, and also in the various valleys whose drainage passes into that river. The grand valley which divides the military sanitarium of Kussowlee from the military station of Subathoo, terminates in the valley of the Sutledge. The hot and lower parts of this valley are well supplied with "Bair," (*Zizyphus Jujuba*) and *Jher-baeree*, (*Zizyphus Lotus*) jungle, and the grand tusser silkworm is freely met with. The mulberry is common all over the higher parts of the hill sides from below Subathoo and north-west of Hurreepore dâk bungalow. On these mulberries the genuine wild silkworms of the Himalayas (*Bombyx Huttoni*) is always to be found. In October 1862 I sent some of these cocoons to Calcutta, and the silk was most favourably reported on, being declared by competent authority to be "fully as good in quality as the best Bengal." The colour of the silk was white.

These wild silkworms will not feed if removed from the trees, and the only way of turning them to account would be to have a dwarfed mulberry plantation made, the trees or mulberry bushes being closely planted, so as to make a running hedge and kept down by cutting to the height of seven or eight feet. The hedge to be protected by common twine netting properly tanned to withstand the rain. A dozen or more of these hedge plantations being formed, the Paharees should be paid so much per hundred for half-grown wild silkworms brought by them to the farm and these should at once be placed on the mulberry hedges and removed as soon as they arrive at the spinning stage. To secure a good supply of eggs, selected cocoons should be tied on to twigs, so that the moths in due course would lay their eggs where it suited their convenience. The eggs laid in October would be hatched in April-May next spring, and the eggs laid in July-August, would produce the second set of cocoons and moths whose eggs would hatch in the following spring. Thus it will be seen that this wild silkworm produces two silk harvests within the year, the first being the spring, and the second the autumn crop of cocoons. The whole of the operations would be outdoor work, and the principal outlay after the mulberry hedge plantations were formed, would be the cost of the nets, *mesh* one inch, and as the Paharees understand knitting, the art of netting would soon be acquired, and with Bengal twine to hand, the nets could be made at a very moderate cost. The removal of the worms in doors when arrived at the spinning stage, is an easy matter, and they might be allowed to spin on the hedge and the cocoon be removed in due course.

The locality we would recommend is the land near "Kukree Huttee," on the old road to Simla. The buildings of the hotel there are sufficiently extensive, and the property could be purchased for a moderate sum. The next locality would be in the neighbourhood of the Hurreepore dâk bungalow, but as the land belongs to the Puttiala Rajah, objections might be raised by the Durbar. However from below Subathoo to "Kukree Huttee," hotel there is ample room for half-a-dozen large silk farms, and these once established, the paharree zemindars would soon form mulberry plantations and sell the cocoons at the factory.

The formation of "Bair" and bush "Bair" (*Jher-baeree*) plantations in the same locality is easy of accomplishment, in fact if land be available, transplantations of bushes from the jungle could be carried on at any time as water is freely and always available. To stock such plantations with tusser cocoons, would not require much trouble or outlay, and after the first supply of eggs had been laid, the extensions of tusser silk raising would depend on the increase of bush "Bair" culture.

The paharees would take to this pursuit as soon as the value of the "Bair" was known, and raising tusser worms thereon understood. The collection of tusser cocoons in the jungles growing "Bair" would become a regular occupation and wild silk gathered in the jungles on both sides of the Sutledge would soon be brought to Subathoo and "Kukree Huttee." To show how freely the bush "Bair" grows in these hills we would wish to mention that from Kaepu on the right bank of the Sutledge, and within the boundaries of Kotgurh to twelve miles higher up the river's course, the bush "Bair" is the principle plant of the jungle. Now if a tusser farm was established at Kaepu, and steps taken to introduce a good supply of unhatched tusser cocoons, the cultivation of the bush "Bair" being carried on, the locality would in two years swarm with tusser silk worms and tusser cocoons in abundance.

The power to sow bush "Bair" seeds in the jungle would we presume be granted by the Punjab Government, and once in fruit, the foxes and jackals who feed thereon would extend the growth in the usual manner, for the voided seeds speedily germinate, the plants bear fruit, and further extension follows. From Kaepu down stream to the bridge over the Sutledge the bush "Bair" is common, and no doubt the opposite bank of the Sutledge is as well supplied. Hence it only requires a little management and some capital to convert miles and miles of unprofitable hill side into vast breeding grounds for the tusser silkworm. The opposite or Kulu bank of the Sutledge is British territory, but how many miles down the river it extends before meeting foreign territory we do not know.

We are convinced that if the subject of tusser silkworm breeding, and the planting of *Jher-baeree* and "Bair," seed-stone were lucidly explained to the various hill chiefs owning territory from Roopur up to Ranipore in Busahir that one and all would take the matter in hand in order to increase their annual income by this most simple, inexpensive, and highly profitable measure. It should further be explained that the lac insect, *Coccus lacca* breeds freely on all kinds of "Bair," trees and bushes, and that once introduced from the plains, propagation and extension will go on year by year till the valley of the Sutledge becomes a regular mart for the sale of seed lac, and its easiest made product "shell lac."

These hill chiefs are perfectly alive to their own interest but at present they know very little about the tusser silkworm and less about the lac insect, and we fear that this ignorance will continue until Subathoo has its silk farm, and a Government nursery is established at Kaepu for raising the common "Bair" tree of the plains preparatory to placing tusser cocoons thereon, and in due time removing young but well grown silkworms from these trees to the bush "Bair" jungle extension on both banks of the Sutledge river.

From this nursery various hill chiefs down to Belaspore could be supplied with "Bair" tree seedlings, and subsequently with tusser cocoons, a trained native being sent to show how to place them on the trees and transfer the young worms to the wild bush "Bair" In four or five years from date of commencing work, the Kaepu property would have become valuable, and then European capitalists would we think be forthcoming to purchase the same, and so recoup Government for its outlay, and relieve it of its duties as pioneer of tusser silk farming operations.

CULTIVATION ON VILLAGE-SITES.

One of the most unsatisfactory features about the annual settlement of the revenue in Madras, is the cultivation of waste land situated within the village-site (Nattam.)

The Board and Government insist on all such cultivation in excess of the extent allowed by the rules for house-site, &c., backyard being absolutely prohibited on the ground, that it may be wanted for building purposes, and the result is that villages are free of unsightly waste grounds covered with prickly-pear and filth of all sorts. This looks very like killing the present generation for the sake of prosterity, and we cannot help thinking the policy is entirely wrong on every ground, financial, sanitary, and agricultural. It is wrong financially because some of this cultivation having been surveyed, it depends almost entirely on the Curnam, how much of it is brought to account, and who is made to pay for it. Moreover the uncertainty as to the assistant is a direct incentive to evasion by collusion between the Curnam and the cultivator. That it is bad from the sanitary point of view, it requires no argument to prove, the backyards of houses in villages are often filthy enough, but the very filthiest *foci* of disease are to be found in the waste uncultivated patches covered with prickly-pear and abounding in snakes and offal. Such pieces of ground if regularly cultivated, would produce considerable supplies of these vegetables which are so much required in this country, and the filth that formerly produced nothing but disease would, in the form of manure, become the chief means of producing them.

Then from the standpoint of the scientific agriculturist, what can be more discouraging than to find an agricultural population living away from their land? Think of the waste of manure and the waste of time that are involved in the present system, why endeavour to extend it? Why not rather *compel* the people to live on their land? The practice of living in villages was only an advantage when they were walled and offered some protection, however slight, against the attacks of marauders or even invading armies. Now walls are no longer required, and in the interests of sanitation and agriculture the practice of trading together simply because it is the custom, and no longer because it is necessary, should be discouraged in every possible way. Land within the village-site should therefore be freely given for cultivation, and given on puttah, so that if people will insist on living in a crowded unwholesome village to the great detriment of their neighbours as well as themselves, they should be obliged to pay for the land. Why should land so invaluable for the production of vegetables be kept out of cultivation for the sake of a posterity which it may be hoped will have more sense than to live on it?

It is argued indeed that if such land is allowed to be cultivated, the remainder of the village-site will be more crowded than ever, but that is almost impossible. A native family never breaks up and occupies fresh ground, until the house has been split up into infinitesimal portions, and its inmates crowded to the verge of suffocation.

EDITORIAL NOTES.

In our issue for May, we had an article on Sugar-cane, in which from the carelessness of our printers the word Beheea was used throughout for Belna. We made a short correction in a later issue. Considering, however, the harm that such a mistake was calculated to do the patentees of the Beheea mill, Messrs. Thomson and Mylne, we have pleasure in inserting the following letter from these gentlemen. "The short mention made in your issue of June 1st, regarding the misprint in the article on 'Sugar-cane,' which appeared in your May number, should, we think, be supplemented in justice to our cane mill and in order to counteract as far as possible the misleading effect of the printer's error: we would be obliged therefore by your finding room in your next issue for the following in the form you may consider best:—

"The Belna, not the Beheea mill, is worked by eight bullocks, and requires sixteen for a working day of eight hours; the Beheea mill is usually, and ought always to be, *worked by a single bullock*, but in some districts of the N.-W. P. where the cultivators have as yet no bullocks trained to work singly they at present, for that reason, insist on yoking a pair instead of a single bullock; this, however, is an utter waste of power and money, and worse, as it brings a considerable amount of useless strain on the machine: this, Mr. Campbell, Superintendent of the Government Engineering Works at Roorkee and other experienced officers of Government can testify. The mill is by many cultivators worked day and night so as to get a large area of cane squeezed by the one mill within a limited time, and where this is done, of course a relay of cattle is needed, as the one bullock cannot go on working day and night without rest or food. In this case the two or more cultivators who have agreed to use the one mill, club together and all their cattle work in turn for two hours or so. If properly set and managed, the mill is quite easily and efficiently worked by a small bullock such as the Behar farmers use in their ploughs. In Shahabad, Gya, and other districts of Behar there are thousands of cultivators with small holdings who do all their ploughing well-irrigation and the squeezing of their Sugar-cane with the one pair of well trained, well fed bullocks. The Beheea mill in place of being a "rude heavy machine" weighs only five Calcutta maunds (4½ cwt) and is the lightest as well as most efficient machine ever constructed for such work as it is equal to. Its lightness and compactness are two of its great recommendations, and these good qualities combined with its efficiency, portability, and cheapness for the work it can do are so manifest to the cultivators of Bengal and the N.-W. P., that no less than 15,000 of them have been taken by them since 1874, when after many trials and by patient persevering endeavour, continued through several years, what was begun to aid our own tenants on the Jugdespore estate was brought into such efficient form that cultivators from villages around and at a distance began to come in yearly increasing numbers, wanting us to supply them with mills. The number supplied last year was very nearly 4,000, while through we have no guarantee and have to venture a large amount of capital, we are preparing for a demand considerably in excess of this during the coming season. The cane has to be passed through these native mills several times before the whole of the juice is expressed, but by the Beheea mill, if properly used, this is effected by once passing through, so saving a large amount of time and expense, and securing a better cleaner juice. Thousands of mills can be seen at work doing this in the Shahabad, Gya, and other districts any day during the sugar-cane harvest."

Dr. Bidie furnishes to the Madras Government, a memorandum on the various grains indigenous to the Southern Presidency. These number forty-three. In each case he gives local names in several languages, and this cannot fail to be exceedingly useful for purposes of identification. He also forwards samples accompanied by descriptive remarks. The Government have directed the entire collection to be forwarded to the Secretary of State; with a view to have them valued and reported on generally.

Mr. W. R. Robson, M.R.A.C., has been experimenting with Madagascar paddy. The result was an average outturn of 1,164lbs. grain, and 2,616lbs. straw per acre, which are not particularly good. If he is right in supposing the Madagascar grain to be same as has now developed into the Carolina rice, we fear it is not adapted to India. The Carolina rice has a tap-root more or less developed, and hence seeks its sustenance lower down in the soil than does the ordinary country grain. Our mode of cultivation—which consists in scratching the extreme surface—offers no help to this new variety. It is wise, however, to continue the experiments in this direction, and with this end in view Mr. Robertson notifies that he has 1,979lbs. available for seed, and he says in this connection "I shall be glad to receive indents for small supplies to be experimentally sown on land watered by the south-west monsoon."

The preservation of insectivorous birds has been pressed on the attention of the Madras Government by Dr. Bidie. His counsel is that birds that feed on insects should be protected by law from being destroyed for the sake of their feathers, as they afford an effectual help against the visitations of borers, locusts, and a host of insatiable grubs. The doctor, in alluding to some of the Australian colonies, says:—"In Victoria, there is issued to all

State schools a diagram exhibiting 36 colored figures of birds which eat insects, and are therefore protected by law as friends of the farmer and colonists generally." He refers to the injuries inflicted on crops by insects in Southern India, and remarks that "there is iminent risk of such pests increasing largely, if measures be not adopted to protect their natural enemies the insectivorous birds." The Madras Government has recommended to the Supreme Government the passing of a general Act to regulate netting and other means of capture or destruction of birds. The best methods of impressing on children in schools the value of birds to agriculture are without delay to be considered. In Bangalore and throughout Mysore a like measure of prevention is needful. Numerous stuffed birds hawked about by natives are to be had for a mere trifle, owing to the absence of anything like a check against the wholesale destruction of the feathered tribes.

THE Irrigation Report of the North-West Provinces for the *rabi* season of 1880-81 shows that the total area irrigated was 1,032,010 acres, or over 188,000 acres more than the irrigated area of the previous *rabi*, but less by 43,942 acres than the area of 1878-79 which was the largest on record. The increase since last year was due to the deficiency of the monsoon rainfall.

"LAST year during July and August I was conducting a series "of experiment on aloe fibre and used your mill to crush the "stalks. Nothing could have been more satisfactory than the "manner in which the machine did its work. The machine I "calculated would enable me to put the dressed fibre into the "Calcutta market at a cost of about Rs. 6-8 per maund, leaving a "clear profit of Rs. 1 per maund."

IN an article on "The future Wheat Supply," the *New York Tribune* takes exception to the estimates of Messrs. Read and Pell in respect of the cost of producing wheat in America and sending it here. The *Tribune* says it is not improbable that this year may bring the competition between American and European farmers to a crisis. The United States will likely have more than 200,000,000 bushels of wheat to sell, while the deficiency in Europe may be much less than that quantity. In that event the weakest will go to the wall. The cost of producing wheat in America, the *Tribune* declares, is less than that stated by the Assistant Commissioners. The British farmer, it says, will have to sell wheat at 38*s*. per qr. in order to keep the home market to himself.

THE agricultural statistics for Australia for the year ending March 31, 1881, were published in the *Government Gazette* about a week ago. According to them it appears that there was a serious decrease in the average yield per acre of our principal agricultural products. On wheat, however, which is now the chief grain crop of the colony, there was an increase in the total amount, as compared with the previous year, of 320,191 bushels, owing so much larger amount of land having been sown with wheat than was sown in the year ending March 31, 1880. In 1871, 284,167 acres were placed under wheat cultivation, and 1881, 976,416 acres. The acreage under oats decreased from 149,309 acres in 1871 to 133,910 acres in 1881, while the area under potatoes increased from 39,026 acres to 44,733 acres, and under hay from 163,181 acres to 249,424 acres within the same 10 years. The average returns per acre of our four principal crops in the year ending March 31, 1881, were as follows:—Wheat, 9 9 bushels; oats, 17·6 bushels; potatoes, 2·7 tons; hay, 1·2 tons. The corresponding averages per acre of the same crops in the year ended March 31, 1880, was:—Wheat, 13·3 bushels; oats, 24 bushels; potatoes, 4 tons; hay, 1·5 tons. In 1871 the colony produced 2,870,409 bushels of wheat, 2,237,010 bushels of oats, 127,579 tons of potatoes, 183,708 tons of hay; and in 1881, 9,719,049 bushels of wheat, 2,358,459 bushels of oats, 124,706 tons of potatoes, and 300,184 tons of hay.

IN a recent letter the Acting Commissioner of the Nilgiris requested the sanction of Government to sell the jalap tubers grown at Ootacamund at a moderate price, to be determined in communication with the Superintendent of the Gardens. "There is a large demand for the plant, and up to the end of March last, 4,201 tubers were supplied to applicants from various parts. In one case, Mr. Jameison inadvertently charged for 1,000 tubers at Rs. 5 per 100, and received the amount Rs. 50. It is impossible to meet the large demand out of the very limited cultivation of jalap now carried on in the gardens, while to extend it for gratuitous supply would partly absorb the small revenue derived from other sources." The Government have approved of the sale of the tubers at a very moderate price.

THE following interesting sketch of the Persian opium industry is by a correspondent of the *Pioneer* who dates from Yazd. "Any information about India is gladly received by them, as relating to a great trading country, and the grand rival of Yazd in its staple product—opium. Rival, indeed, is hardly the right word, for the opium export of India is more than ten times that of Persia; still the advances made in opium cultivation and manufacture in Persia within the last few years are well worthy of notice, and under a more active Government might bode interference with a main source of Indian revenue. Within ten years, the weight of exported opium has doubled. It was 4,000 chests in 1871-72; it will reach 8,000 this year. Each chest contains 10½ shaki mans, each man being 512 tolas, or 6⅖ seers, thus the chest weighs 67¼ seers and the total export this year amounts to some 13,440 Indian maunds. It goes direct to Hong-Kong, where the principal Yazd merchants have representatives. Why Yazd should be the great opium emporium of Persia, appears to be explained by two reasons? In the first place it is in the centre of the opium-growing country. Wherever one halts, between Karman and Yazd, the wide fields of poppy challenge attention, and it is the same towards Ispahan and around Ispahan itself, where even more poppy is grown than about Yazd."

AMONG local products which are worthy of attention is the wild lavender. It grows luxuriantly all over the hills, and flourishes at Ootacamund. The dried flower stem, we believe, commands an excellent price in the home market, and is quoted at £60 per ton. This is almost as good as coffee at present. The plant thrives without attention, and the stem requires no preparations. We are unable to tell the yield per acre, but this must be considerable, as the flower stems rise in great profusion, and the cultivation may be indefinitely extended. The records of the Government gardens ought to contain information regarding the late Mr. McIvor's cultivation of the plant, which if given to the public might be useful just now.

THE keeping of bees has never been common in this country, and it is a little strange that this should be so. The expense attendant on this industry is practically *nil*, and the profits considerable. A market can usually be had for good honey, and even if this were not the case, the produce cannot fail to be a grateful addition to the villagers' food supplies.

THE following sentence is from the Indian Famine Commission Report, and points to the want of enterprise in India. "The obstacles that stand in the way of the investment of English capital in India, such as the climate, the distance and the want of exact knowledge of the country, are still very great, and it may be feared that the disinclination to risk such investments has been rather increased than diminished by the system of giving a guarantee of interest at a high rate on the large capital of the great railways. So long as the opportunity was afforded to capitalists to make advantageous investments on a large scale on the security of the State, the inducement to attempt any enterprize without such security must have been greatly diminished."

THERE is no doubt a considerable amount of truth in this, and the idea of guaranteeing various classes of industries is of course out of the question, we would, however, make an exception in favour of railways, and principally for the reason that they are practically public works, conferring many advantages on the public service. We also think that Government might help forward many struggling industries, not by way of guarantee, but by offering premiums and prizes for improved methods of manufactures, &c., a little help in this direction would do much to foster new, and help on old industries.

A CORRESPONDENT of the *Bendigo Independent* thus testifies to the curative properties of gum leaves:—"I will relate something

respecting the curative properties of the gum leaves. I am acquainted with three persons who have been thoroughly cured of rheumatism by sleeping on beds made entirely of those leaves. Those used were of a round shape, and of a sticky nature growing on young plants, and the nearest to the ground. It is also well known that a dozen of these leaves made into a decoction of tea are good for a cold or for inflamed eyes. Further if a few of the leaves are rubbed smartly betw een the palms of the hands and immediately held to the nostrils, taking a lengthy hard sniff, a most refreshing sensation will be the result."

OUR up-country contemporaries speak of a very rich fruit harvest as being ripening in Kumaon this year.

THE Japan Government have also instituted an Agricultural Department, and a following list of subjects to which the attention of the department is directed, would do for the consideration of our own new department. "The matters submitted for consideration by the assembly of local officials charged with development of agriculture in their respective provinces are reported to be: (1) Revision of the methods enployed in preparing agricultural statistics. (2) Exchange of seeds (between the different prefectures) and their transport. (3) Supply of manure. (4) Establishment of a Society for investigating fishery affairs; and the protection of marine production (*e.g.*, fish, sea weeds, &c). (5) Subject of rewards granted for meritorious services calcutated to promote agriculture."

THE experiments now being carried on at the Saidapet Farm, Madras, with cattle breeding with stock imported from Aden, seem to be succeeding. The satisfactory results that have attended the importation of Aden cattle into Madras, have induced the Board of Revenue to sanction a further outlay of Rs. 1,200 for the purchase of fresh stock for the Saidapet Farm. The bulls that are now to be ordered "should," the Superintendent of Government Farms says, "not be over five years of age, should be docile, and of a good shape; the cows should be young and by preference, rearing their *first* calves; and that they should undoubtedly be good milkers and docile; the whole of the stock to be in perfect health."

THE revenue from opium is very much above the estimate and this is all the more remarkable, when we reflect on the fact that Persian opium is coming to the front with rapid study. The latest reports we have from China quote the following prices, in dollars per chest:—

Malwa from	... ...	680	to 740
Patna „	... ...	577½	to 595
Persia „	... ...	535	to 577½

It is therefore fast overtaking Patna opium in Chinese estimation, and a very few years ago it was quoted at less than half the price of the Indian drug.

THE largest purchase of land ever made by a single person was effected last month. Mr. Hamilton Desson, a manufacturer of Philadelphia, concluded a contract by which he secured 4,000,000 acres from the State of Florida. The land formed part of the public domains of the State of Florida, and was under the control of the Board of Internal Improvement for the State. Mr. Desson's intention is to work out a great emigration scheme with offices in England, Germany, and France. If some of our wealthy native magnates would invest their capital in purchasing or renting large stretches of land, and would encourage cultivators to work under them, much good might be done to India. They would require to make certain advances to ensure good crops, and could make those advances under an arrangement to receive a certain percentage of the crops in return. By this means many young men might be more usefully employed than in hanging about the residences of their relatives doing nothing but indulging in laziness—and worse, and would, besides making fortunes for themselves, be the instruments of conferring lasting blessings on their poorer countrymen.

A BOMBAY contemporary is inclined to indulge in pœans of joy over the prospect of a large portion of our native business being transferred to the western capital. He says "In the memorial of the Calcutta shroffs, mahajans, and dealers to the Agent of the East India Railway, it is stated as a matter of painful regret to the memorialists, that several firms of good repute have lately, in consequence of the opening of the Rajputana line, established agencies in, and sent representatives to Bombay. The matter is not fell to be one of painful regret here, and if the memorialists should be obliged, as they hint, to give up their business in Calcutta, and proceed to Bombay they will be cordially welcomed." This is quite legitimate, and it will be the fault of our railway authorities if such a change takes place.

REUTER announced recently that tropical weather is being experienced in England. "When the last mail left the subject of the weather was attracting more than ordinary attention, which is saying a good deal. The hay crop was a failure in consequence of the dry and ungenial weather which distinguished the once merrie month of May, but the grain and root crops taking them altogether, promised well. Wheat, though thin and rather backwards (says one authority), looks strong and healthy, and has advanced rapidly since the rains of a fortnight ago. In Devonshire it is said not only to be of a very fine colour, but to be thick on the ground, and fast bursting into ear. From some of the chief corn-growing districts however, the report is not quite so good as this. In Lincolnshire we hear of a good many light crops, and in the eastern counties the crops are not reported to be heavy, though they look remarkably well. In Sussex wheat is not "promising," though a fair crop may be expected. Oats and barley and beans are favourably spoken of, but on some soils the former will be rather scanty, as much of the seed sown never appeared above the ground, in consequence of the parching weather. Of root crops the accounts vary greatly. In many districts they have been attacked by the fly, and the rain has come too late to save them; but there is plenty of time still to sow the fields over again, and to have a good plant on the ground by the beginning of September. Potatoes, though late, are reported to be vigorous and healthy both in England and Scotland. And from both North and South alike we hear of "abundance of summer food," that is to say, on the grass lands there will probably be a rich aftermath, while hedgerows, ditches, &c., show abundant signs that the season has been in some respects one of luxuriant vegetation. In Lancashire the enormous numbers of buttercups and the abundance of May-blossom are noticed by agricultural correspondents. If from grass and corn we turn to fruit prospects, we find that here too, the reports are of a mixed character. From the cyder counties excellent accounts are given in the home papers of the apple crop and gooseberries, currants, and strawberries are all said to promise very fairly." What strikes one, in reading this, is the prominence given to crops intended solely for cattle-food, as hay and root crops. In India such a thing is unknown. Cattle are fed on what may be called the "waste products" of agriculture, and no ryot ever thinks it necessary or even advisable to grow anything wherewith to feed his cattle.

SEVERAL native princes have nominated students to attend the Sydapet School of Agriculture. These students are supported while attending school. Such a system is *calculated to make* the school popular, and if a proper selection be made, cannot fail to repay those States in results. There are at present thirteen of such students supportted by nine States, and the Superintendent having intimated that he has accommodation for as many more, it is to be hoped that others will follow the good example.

AN interesting article on the paper manufacturing industry from the *Madras Standard* will be found among our selections. We insert it because it opens up the subject of growing plants for paper-making. There are really hundreds of different plants in India admirably adapted for paper-making, and the largest number of these can be cultivated at a nominal cost. This subject is coming to the front, and the doubt recently expressed by Lord Hartington, as to India's ability to furnish paper ought to lend additional force to the movement.

The latest official report from the Central Provinces tell of steadily improving prospects. Public health, which has suffered much recently from cholera and small-pox; of the latter complaint the report is silent, the epidemic having disappeared, and cholera, in a mitigated form, is reported only from the districts of Raepore, Damoh, Nursingpore, Seonee, Jubbulpore, and Saugor. Rain is falling in fair quantities, and the agricultural prospects are good. Trade continues brisk and the material condition of the people is satisfactory. The *kharif* sowings are over in many districts, and are proceeding fast in others. Food-grains are now quoted as follows, in seers per rupee.

	Rice.	*Wheat.*	*Jowar.*
Sumbulpore	45½	...	...
Raepore	35	41	...
Chanda	15	23	33
Mundla	21	31	35
Khandwa	...	20	40
Hoshungabad	9	18	36

Mr. St. George Tucker's note on cattle disease is the most important contribution to the subject which has been made for some time. We can remember in one of the earliest visitations of Asiatic cholera, it was discovered that the district of Hungary in which extensive salt mines are situated, was entirely passed over by the plague. This gave rise to inquiries which we remember led to the opinion being generally held that a free use of salt was a preventive, and from our own experience we can recall a circumstance which adds weight to Mr. Tucker's suggestion. We remember a gentleman who had charge of a large estate in Upper India, telling us that during all the years in which he had charge of the property, on which there were several hundred head of cattle, he never had any disease among them, although all around cattle disease might periodically have been raging. He attributed his freedom from these complaints to his habit of allowing the cattle a certain quantity of salt daily. The total cost of this was scarcely appreciable, and the result was satisfactory. We observe one or two of our contemporaries inveighing against the salt tax, as the cause of this inability on the part of the people of India to supply this necessary article to their cattle. This is absolute nonsense. We should like to see the rate of the duty considerably reduced, but even at its present rate it is very far from being oppressive. The total gross revenue from the salt duty, as recorded in the last budget was £7,266,413, which sum, divided among the two hundred millions of India, is equal to 8·72*d.* per head per annum, and when it is considered that this is practically all the taxation borne by the great mass of the people, the cry against the salt-tax is meaningless. The reason why the farmers do not, as a rule, give their cattle salt, is because they are utterly callous as to the comforts of their cattle. A visit to an ordinary *bustee*, will convince any reasonable man that the Indian ryot does not possess a spark of feeling for his cattle. He does not care how they are housed, so long as they are sufficiently covered in, to prevent them catching cold, and being unable to work. Did any one ever see a villager scattering grain to fowls in this country. No, all animals are allowed to live, they are not helped to live, and if they somehow contrive to exist at all, it is not because of any care bestowed on them by their owners. We hear of animals in good condition obtaining prizes at home. This is a sort of thing which the ordinary ryot utterly fails to appreciate.

The quantity of wheat exported from Bombay is assuming vast proportions, and during 1880 no less than 195,000 tons were despatched from that port alone. This matter is being pretty fully discussed at present, and this it is which doubtless has led to the reduction in carrying charges on the East India Railway to which we have already referred to. These reductions, however, do not refer to stations above Patna, and if this line is desirous of intercepting a large share of this traffic, the rates from stations in Upper India must also be overhauled. That this traffic is worth striving after, will be clearly seen when we are told that this quantity is equal to about 800 trains carrying 250 tons each or about 30 trains a week. Grain carried as wheat is, gives less trouble than general goods; as a rule it comes in whole wagon loads, and gives comparatively little trouble. Another great advantage is that, as a rule, it is all "through" traffic; trucks are picked up at several stations, and once the requisite number of wagons are secured to form a train, there need be no further stoppage till Howrah is reached, other than may be demanded by the traffic rules of the road, and for the necessary changes of engines and guards. There can be no doubt that if the East Indian line were doubled all the way to Delhi, a very large share of this traffic would find its way to Calcutta, in spite of the shorter route now existing by the Rajputana, and Bombay, Baroda, and Central India lines. The break of gauge on that route necessitating a double breaking of bulk makes that route unpopular, as, in spite of the utmost care, bags of grain sustain much damage by this transhipping,—if the phrase be admissible as applied, to trains.

Upon the whole we do not think that Calcutta has much to fear on account of the opposition lines to Bombay, at least so far as Upper India is concerned, but the line at present in course of construction, eastwards into the Central Provinces from Nagpore, will perhaps prove a great help to Bombay. At present it does not pay to send the cheap Central Provinces' grain to any seaport; the want of roads being an insurmountable difficulty. As an illustration of this, it is affirmed that it takes more to carry wheat from the Central Provinces to Bombay than it does to convey it from Chicago to Liverpool. This of course handicaps India, at least that portion of it, and the same remark may almost be made regarding the other districts in which wheat is available for export. This subject derives extra importance from the latest news from America telling us of the failure of the American wheat crop. As matters connected with inland transport are at present managed by us, India can never be said to compete with America in supplying the English market. Barring this difficulty, there is no reason why India should not be an active competitor for a share of this traffic, instead of standing comparatively idle in the contest, sending home a large supply only when certain special conditions of the market transpire. She ought to be in a position to send all our surplus stock, with a reasonable hope of profit nay more, she ought to grow wheat for the express purpose of supplying the English market. The quantity of wheat sent to Europe last year for Bombay was 195,000 tons, equal, commercial men tell us, to three hundred thousand steamer tons. In other words, sufficient to load 150 steamers of 2,000 tons each.

The Liverpool *Journal of Commerce* says that "at the Liverpool Corn Exchange a sample of wheat transmitted by the Hudson's Bay Company to Mr. Drake, Canadian Government agent in Liverpool, was carefully examined by several of the leading importers and millers present. These gentlemen pronounced it to be the finest sample of wheat in the market, and as a consequence offers of 3*d.* per bushel were made more than for the finest samples of Californian."

The recent returns published by the Registrar-General respecting our recent harvest are of unusual interest. They relate only to the production of wheat, but even with this limitation they tell a surprising tale. Wheat is now of importance to this country almost equal to gold or wool. If our wool is worth three millions and-a-half, and our gold is worth three millions, our wheat crop of this year would be worth, if delivered at an English port, upwards of two millions and-a-half. Within the last six years the acreage under wheat has been nearly trebled. It is, therefore impossible to deny to this industry a front place in our occupations. Consequently every change in its productiveness becomes a matter of national concern. It is thus a subject of deep regret that the results of the harvest have been by no means such as we could desire. The yield per acre has been less than that obtained in any year for last ten years, with the exception of the unfortunate harvest of 1879. Although the area under wheat has, as compared with last year, increased by nearly 221,000 acres, this increased area gives an absolute decrease of about 265,000 bushels. The average of last year was 13·29 bushels to the acre. The average of the present year is only 9·84 bushels.

On the subject of producing fruit in Upper India, a correspondent from Simla writes to a contemporary, tells what is being done at Simla. He says:—"We have not had any rain

for two or three days, and the weather is perfect. I went down to the Annandale gardens on Thursday, and was astonished at the fine show of flowers, vegetables, and fruit ; the latter is not ripe, but promises to give a fine crop, the apples particularly being in splendid condition. When I say that the apples, which are almost all of a good English sort, are sold towards the end of the season by auction at from Re. 1-8 to Rs. 2 per seer, you will see what a good thing can be made out of a well managed fruit garden. One or two private persons in Simla have already followed the lead of the Annandale gardens, and even at this early date a few good English apples can be obtained, though they fetch exorbitant prices.

IN South Western Russia, between the Baltic and the Black Seas, the sunflower is universally cultivated in fields, gardens, and borders, and every part of the plant is turned to practical account. A hundred pounds of the seeds yield forty pounds of oil, and the pressed residue forms a wholesome food for cattle, as also do the leaves and the green stalks cut up small all being eagerly eaten. The fresh flowers, when a little short of full bloom, furnish a dish for the table which bears favorable comparison with the artichoke. They contain a large quantity of honey and so prove an attraction to bees. The seeds are valuable food for poultry ; ground into flour, pastry, and cakes can be made from them ; and boiled in alum-water, they yield a blue coloring matter. The seed receptacles are made into blotting paper ; the woody portions are consumed as fuel, and from the resulting ash valuable potash is obtained. Large plantations of them in swampy places are a protection against intermittent fever.

THE boring of the now famous artesian well at Vittoria (Spain) has reached the immense depth of more than nine hundred and seven metres (2,975 English feet) without the nature of the rock bored through changing in the slightest degree since the works began. Geologists are astonished at the thickness of the rock, for there is scarcely a well in the world which reaches the depth of the Vittorian one."

A WISCONSIN farmer has sold for $27,000 black walnut trees from 10 to 20 inches in diameter, which he planted 23 years ago on a piece of waste land unfit for cultivation.

IT is estimated that the United States is capable of maintaining an area of 200,000,000 acres of corn-land, which, with the average yield of the past ten years, would yield upwards of 5,250,000,000 bushels of corn.

THE profits derived from ostrich farming are so great and the returns are so quick, that it has led to the majority of the farmers in South Africa, investing their all in this new industry (to the neglect, in too many instances of their legitimate calling), which from its nature, depending in a great measure, as it does, on the caprices of fashion, must necessarily be a transitory one. Valuable land is left untilled, sheep-farming is dying out, the natural resources of the country remain undeveloped, and when the day comes, which it assuredly will not many years hence, when ostrich feathers will be a drug in the market, and unsaleable, the agriculturist will find to his sorrow that, in his "haste to be rich," he has been pursuing a shadow, and is landed in poverty.

WE understand that the Royal Commission on Agriculture have resolved to obtain a supplementary report on American agriculture. The intention is to have the state of American agriculture down to the present day recorded and laid before British readers. The responsibility of furnishing the supplementary report could not, perhaps, have been entrusted to a more competent pen than that of Mr. John Clay, jun., whose reports to the Commission on American stock raising and Californian wheat growing have been perused with so much interest.

THE New Zealand Government has taken in hand the fostering of new industries, and if only our Government would exhibit half the zeal shewn by the Colonial Government referred to, we should soon see a change in our industrial and manufacturing concerns. "During the present year alone it has announced its readiness to give a premium of £1,000 for sugar made from beet grown in the colony ; £500 for linseed-oil, and £100 for oil-cake from seed grown locally ; £300 for starch ; fifty per cent. on the value of silk cocoons, up to a limit of £1,000 ; £500 per annum, for three years, for sulphuric acid ; £250 for hardware ; £500 for the first fifty tons of cheese of fair quality produced in a factory worked on the American principle ; £500 for the first hundred tons of fresh meat exported to England in a refrigerating chamber and landed in marketable condition ; £500 per annum, for three years, for refining a hundred tons per annum of cane sugar, and a bonus for starting a factory for sporting and blasting powder." At our exhibitions and agricultural shows prizes of 10 rupees or so are offered. This has very little effect, but if we had the chance of obtaining £1,000 as the reward of our enterprise, much more might be effected.

THE following remarks on the American wheat crop of the current year, from the Chicago paper will be read with interest, although they tend to mystify us still further :- "The *Chicago Tribune* declares that careful investigations of heavy capitalists as to the present position and future prospects of the wheat crop have resulted in proving (1) that the winter wheat crop of the States will only equal two-thirds of last year's yield ; (2) that the acreage sown to spring wheat is only four-fifths that of 1880 ; and (3) that at the present time only 7½ million bushels of wheat remain in the hands of millers and in elevators in the country. The *Chicago Times* remarks that if these estimates be correct, America has only wheat enough on hand to supply her own wants till harvest time, and that her wheat crop of this year will merely supply the demand of the home market without yielding a single bushel for export abroad." However much this may affect the purses of the American exporters, there can be no doubt that it opens up a bright prospect for the Indian merchant, and, as a natural consequence, for the cultivator as well. This information is not credited in London. The *Pall Mall Gazette* say—"Surely news of such importance—portending, if it be authentic, the failure of the chief source of our bread supply—should reach us through other channels than the columns of our Chicago contemporaries." We shall look for further information with interest.

A TELEGRAM from Reuter tells us to-day that the American wheat harvest, which has been in-gathered, is 25 per cent. under the average, and that the French have an average harvest; this cannot fail to mean high prices for wheat in England, and opens out a fair prospect for the Indian exporter. The information we gave yesterday from the Chicago papers was correct, and it now largely depends on the various Indian railways—notably the Great Indian Peninsula and East Indian lines—whether we shall be able to avail ourselves of this opening or not.

THE subject of opening out a land route between India and China crops up periodically. It is now being discussed again, and the favorite route would seem to be that starting from Bhamo. This was doubtless the ancient route, but it has a disadvantage which does not seem to have been observed. The objection to this route is one which does not apply to the road itself, but to the position of its Western terminus, Bhamo. This town is in Burmah, and with a terminus under the government of a country inimical to us, we could not calculate on using this route with any degree of certainty. It may be said that whichever route is chosen, it must run through a foreign country. True, but we should avoid having the terminus outside of our own land. By starting from Sudiya, on the Brahmapootra, we might avoid Burmah altogether, by keeping within the Tibetan boundary. Doubtless some arrangements as to right of way could be made with the Tibetan Government for that portion of the road between Sudiya and the Chinese province of Yunnan, a distance of about 300 miles, and as the Chinese would be equally interested in keeping the route open, we might place some dependance on their securing the safety of the Eastern section. Once the railway is constructed up to Sudiya—which ought not to be much longer delayed—this would be a much

quicker route than by Bhamo, which necessitates a long voyage by water from Calcutta.

We observe with much satisfaction that the East Indian Railway is meeting the grain traffic in a liberal spirit. From an advertisement we observe that the Agency have reduced the rate for grain to Howrah from Rs. 20 per 100 maunds from Rajmehal, to Rs. 29 per 100 maunds from Patna. These rates are equal to ·647*d.* and ·570*d.* per ton per mile respectively, and may be considered very reasonable, considering the comparative nearness of the two stations to Calcutta. This is the way to meet the difficulty raised by the opening out of the Rajputana line to Bombay.

OFFICIAL PAPERS.

THE REVENUE AND AGRICULTURAL DEPARTMENT.

EXTRACT from the proceedings of the Government of India, in the Home, Revenue and Agricultural Department (Public),—under date Simla, the July 1881.

READ the undermentioned papers :—

Home Department Resolution No. 31—1104-1119, dated 14th June 1879.

Home Department Resolution No. 53—2046-2061, dated 29th October 1879.

Report of the Indian Famine Commission, Part 1, paragraphs 118 to 125, and Part 11, Chapter IV, sections 1 and 11.

Despatch to her Majesty's Secretary of State for India, No. 19, dated the 14th March 1881.

Telegram to her Majesty's Secretary of State, dated 10th June 1881.

Telegram from her Majesty's Secretary of State, dated 11th June 1881.

RESOLUTION.

In 1879 under the pressure of financial exigencies, it was determined that the work of two departments, the Home Department and the Revenue, Agriculture and Commerce Department should be amalgamated (some of the duties of the latter being at the same time transferred to the Finance and Military Departments) and that the office of Secretary in the Revenue, Agriculture and Commerce Department should be abolished. This measure was not adopted without reluctance as it was admitted that the system which had been in force since 1870 possessed many advantages.

2. The Famine Commission has now proposed the institution of an Agricultural Department in India. It lays stress upon the importance of rendering *readily* available the accumulated experience of past famines in different parts of India, and has urged that greater attention should be bestowed on the investigation of vital, economic and agricultural facts. Any effectual measures of agricultural and industrial development must, in the opinion of the Commission tend at least to the mitigation of famines, both by promoting the increase of the food-supply amongst a growing population, and by directing industry into new and productive channels. Moreover, it is represented that the Government would obviously be strengthened, in its future dealings with scarcity, by a systematic classification of the experience gained in past calamities.

3. After careful consideration of the views put forward by the Famine Commission, the Governor-General in Council came to the conclusion that full justice could not be done to the important interests which they advocate, and more particularly to the protection of the people from the effects of uncertain season, without some enlargement and reconstitution of the department now charged with those duties. The experience of the last two years, had shown that new additional work could be undertaken by the amalgamated Home, Revenue and Agricultural Department without imposing upon it an undue burden ; and it therefore became necessary to devise some additional means for the conduct of business more immediately affecting agricultural improvements, the social and economical condition of the people, and the material resources of the country. It was accordingly determined to recommend to the Secretary of State the appointment of a new Secretary to the Government of India, to have direct and special charge of these branches of the administration ; and his Lordship has now sanctioned this proposal.

4. It remains to decide what portions of the work at present performed by the amalgamated department shall be entrusted for the future to the new department, and what portions shall continue to be under the control of the Home Secretary. One of the most important objects of the new arrangements is to enable the Government of India to devote increased attention to the important subjects above mentioned; and it would, therefore, be inexpedient to make the new department responsible for all the general and miscellaneous business which, for reasons of administrative convenience, was *formerly* conducted by the Revenue, Agriculture and Commerce Department. The new department will, as a matter of course, control all operations for the relief of famine ; but that part of its functions will be necessarily intermittent, and its main work will lie in the branches of the public administration which most closely affect agricultural development and the interests of the agricultural population. In making the following distribution of work, the Governor-General in Council has therefore, been influenced by the desire to free the new department as much as possible from unnecessary calls upon its energies, in order to direct its efforts, so far as present circumstances admit, to the fulfilment of its most really essential duties.

5. Having regard to these considerations, the Governor-General in Council is pleased to direct that all matters connected with the subject noted below so far as they affect the provinces of British India, shall come under the cognizance of the new Department, *viz* :—

1. Land Revenue including Settlement and Takavi advances.
2. Surveys including Geological Surveys, but ex-cluding Archæological and Marine Surveys.
3. Agriculture and Horticulture, including Fibres and Silk Fisheries, Cattle-breeding and Cattle-disease.
4. Minerals.
5. Meteorology.
6. Famine.

All matters relating to the undermentioned subjects shall be administered by the Home Department :—

1. Law and Justice.
2. Jails and the Penal Settlements in the Andaman and Nicobar Islands.
3. Escheats, and the administration of Estates of Intestates.
4. Police.
5. Education.
6. Examination.
7. Industrial *Arts, Museums* and Exhibitions.
8. Sanitation.
9. The (Civil) Medical Service.
10. The Ecclesiastical Service.
11. Civil Service questions.
12. Registration of Assurances.
13. Patents.
14. The working of the Vagrancy Act.
15. The working of the Arms Act.
16. Copyright.
17. Archæological Surveys and, Conservation of Ancient Monuments.
18. Municipalities and Local Funds !
19. Census
20. Gazetteers.

6. As a temporary arrangement, the Home Department will also be charged with the superintendence of the Forest Department ; and, subject to consideration, the Revenue and Agricultural Department, will temporarily conduct the whole of the business of the Government of India connected with Emigration.

7. The Military and Finance Departments will continue to administer all matters connected with the branches allotted to them by the Home Department Resolutions, Nos. 311—1104-119, dated 14th June 1879, and Nos. 53—2041 2061, dated the 29th October 1879.

8. The new Department will be styled " The Revenue and Agricultural Department," and will be constituted with effect from the 6th July 1881 The officer to be placed in charge of it will have the position, and will exercise the duties of a Secretary to the Government of India,

ORDER —Ordered, that a copy of the foregoing Resolution be communicated to the several Departments of the Government of India, the local Governments and Administrations, and the Officers named in the margin, for information and guidance.

Foreign, Military Finance, Public Works and Legislative Departments! Governments of Madras, Bombay, Bengal, the North Western Provinces and Oudh and the Punjab, Chief Commissioners of the Central Provinces, British Burmah, Coorg and Assam, and Resident at Hyderabad, Surveyor General of India, Superintendent of the Geological Survey of Indi ; Director General of Post Offices in India ; Superintendent of Port Blair and the Nicobars, Sanitary Commissioner with the Government of India, Surgeon General with the Government of India, Registrar, High Court, Calcutta, Secretary, Board of Examiners. Registrar, of Calcutta University Bishop's Chaplain, Curator of Ancient Monuments, Director-General, Archæological Survey of India, and Meteorological Reporter to the Government of India.

Ordered also, that the Department of Finance be requested by a separate Office Memorandum to issue the necessary orders regarding the salary to be drawn by the Secretary in the new department.

(True Extract)

C. GRANT,

Offg Secretary to the Government of India.

TEA AND COFFEE IN BENGAL.

A REPORT on the tea and coffee cultivation in Bengal for the year 1880 shows that the number of gardens under tea cultivation during the year was 274, against 257 in 1879, and the area under plant was, so far as could be ascertained, 38,805 acres against 38,668.

In the Darjeeling district there was an increase of three gardens over the number reported in the previous year, and of 33,854 lbs. in the approximate gross outturn of tea. The year was, on the whole, a favorable one, though the red spider is said to have made its appearance in some of the gardens. The complaints from blight were few, compared with those made in the three previous years. Mosquito-blight, though it did some damage in March and April, was hardly noticeable in the later months of the year when it is generally most active. Labour, which is almost exclusively derived from Nepal, was more plentiful than in the previous year in the hills, but in the Terai it was scarce. The reason of the scarcity of labour in that tract is explained by the manager of a tea garden in the following words :—

"In former times when tea was more remunerative, larger labour forces were kept on the gardens during the cold season ; now more economy is evinced in this point in all the gardens. The coolies, who have been long in a garden, have in most cases become well off, and when the weather is bad and the work was heavy, can better afford to sit idle. The large number of estates opened out in the Terai and Dooars lately, of course, much tend to drain labour."

In the Julpigoree district there was also an increase of 10 gardens over the number returned in 1879. The gross yield of tea amounted to 817,765lbs. against 411,580lbs. in the previous year, thus showing an increase of 406,185lbs. or 98 per cent. during the year under report. As stated in the previous year's report, the gardens in the district

are chiefly stocked with the hybrid plant. Manure is used to a very limited extent, the soil being rich with vegetable deposit. Leaf-rolling machines have for some time past been introduced into the district. The use of a tea-drying machine in one of the gardens is said to have effected a considerable improvement on the results obtained under the old system of drying over charcoal fire, while in another garden, machinery for seiving and equalising tea worked with success. Labour is chiefly imported from Nepal and Chota Nagpore, the indigenous labourers numbering between 700 and 800 only. The labourers are reported to be well-housed and properly treated. One application for lease of lands was under enquiry at the close of 1879, and four applications were filed during 1880. There were thus altogether five applications for disposal. Of these two were granted, one was withdrawn, one was negatived, while one was under inquiry at the close of the year.

There was an increase of two gardens in the Chittagong district over the number reported in the previous year, but the figures are again incomplete, 18 gardens having failed to supply the information sought. The gardens in the Chittagong Hill Tracts have all furnished the returns for 1880, but no figures regarding the yield of tea were supplied in the previous year. A comparison of the results of the year under review with those of the previous year is, therefore, not possible. The weather was not very favourable for tea, and the flushes were below the average. The outturn per acre showed a decrease, but this is attributed to the plucking having been finer than it used to be, the common class of tea hardly paying the cost of manufacture. The soil and climate are well adapted to tea cultivation, very little manure being used. There is an abundance of local labour except at the rice harvest, and the number of labourers imported into Chittagong is small. Improvements in firing and other operations have gradually been introduced, and machinery has been brought into use in several in tea estates the district.

No new gardens were started in the Dacca district, but the average yield per acre shows an increase from 92lbs to 132lbs.

The number of tea plantations in Hazaribagh in 1880 was the same as in the preceding year, but there was an increase of two gardens in the Lohardugga district. One garden in Hazareebagh and three gardens in Lohardugga furnished no returns for the year ; but on those gardens from which returns were received both in 1879 and 1880, the aggregate outturn is said to have shown an increase in the year under report. Early rains in the spring and seasonable weather during the monsoon materially helped to improve the prospects of the industry. The prices, however, showed very little signs of improvement, except for the better qualities which are not yet grown in large quantities.

Coffee is only grown experimentally in the Chittagong district, and those who have cultivated a few plants speak favorably of the growth, especially of the Liberian coffee. No returns have been received from the Chittagong Hill Tracts, but the crop of the Ceylon or common coffee is said to have been a "fair average one" ; the planters have prepared nurseries sufficient to provide plants,of Liberian coffee for 100 acres during the current year. No increase is shown in the number of gardens in the Lohardugga district, and there was a decrease of 320lbs. or 50 per cent. in the total yield as compared with 1879.

ARTIFICIAL COFFEE DRYING.

From the Daily Times, 6th June.
(Translated from the Dutch.)

Report on Van Maanen's method of coffee drying, by the Commission appointed for the purpose by the Commercial Association at Samarang.

We, the undersigned, having formed ourselves into a commission, at the request of Mr. Van Maanen and of the Commercial Association at Samarang, to be present at a trial to be made with a method invented by the said gentleman of artificial drying of coffee, and to give an opinion thereon, have the honour to report the following thereupon :—

The drying apparatus fitted up on the estate belonging to Messrs. F. and A. M. Engelken, named Pendem, in the residency of Surakarta, excels in great simplicity together with inexpensiveness of construction. The trial was made with a quantity of coffee equivalent to about 36 piculs dried and prepared, which had previously been lying 24 hours in the drying receptacles. The operation in the apparatus lasted 22 hours, after which the coffee appeared to be dry enough oto be stored. The operation required little supervision, is extremely simple and inexpensive, about 5½ cubic metres of fuel (jungle wood of all sorts) being used for the drying of the aforesaid quantity. Although we willingly affirm that the drying takes place very equally, and that the coffee is exposed neither to unusual heat nor to injurious vapours, we must, for the present, forbear from passing any judgment regarding the influence which the artificial drying might have on the taste and colour of the coffee, as it is not till after arrival in Europe, it can be ascertained whether the quality has suffered or not. In order to ensure certainty thereon, the Messrs. Engelken intend to forward a consignment of coffee to the Netherlands, assorted in the following manner :—

25 Piculs dried in the usual way in bricked receptacles.

25 Piculs first partially dried artificially and then in the usual way.

25 Piculs first partially dried in the receptacles and then completelyo so artificially.

25 Piculs wholly artificially dried.

This consignment, shipped to the Netherlands and brought to market, will enable brokers to pass satisfactory judgment regarding the influence of the drying method of Mr. Van Maanen on the colour and taste of the coffee. Upon this must depend the final decision on the practicability of this method. Should the result of this trial be satisfactory ; we do not hesitate to recommend strongly this method for all coffee estates, and, chiefly, for those which, from high situation, raise difficulties in the common mode of drying. Although all the advantages enumerated by Mr. Van Maanen in his pamphlet (the expense, for instance, will in some cases, be higher than set forth by him, but nevertheless be far below what the present mode of drying or one of Guardiola's apparatus costs), yet it is beyond doubt that Van Maanen's method presents great advantages which will soon recoup both the expense of fitting up and the cost of buying the invention. In conclusion we note the fact that the trial was witnessed by Mr. D Pies, Head Inspector of the Government Coffee Culture, who seemed greatly pleased with the drying apparatus of Mr. Van Maanen.

Samarang, May 1881.

KAURI GUM OF NEW ZEALAND.

CONSUL GRIFFIN, of Auckland, has written a full report on the production of kauri gum, which is largely used for the manufacture of varnish, of which the following is an abstract :—

It consists of the dried and solidified sap of the kauri tree, a species of pine known to botanists as the *Dammara australis*. It is found only in the province of Auckland, in that part of the colony lying to the northward of the thirty-ninth degree of south latitude, and does not exist in any other part of the world. The largest quantity of marketable kauri gum is dug out of the ground. It is found at various depths, from just above the surface of the soil to many feet below the surface. It is found on bare hillsides, on flat clay lands, in swamps, and even in some places that are covered with a more or less thick coating of volcanic *débris*. Sometimes the gum is found in small detached lumps, and at other times large deposits will be found in one hole. On cultivated land it is not unfrequently turned up by the plough, and in many places the cutting of large drains in swamps has revealed large deposits of this vegetable product. In the forks of the large branches deposits varying from a few pounds to nearly a hundredweight are sometimes met with. When a kauri tree is cut in the bark, even one of the largest and oldest, varying in diameter from six to ten or twelve feet, if the weather be dry, a large mass of half-dried gum will have oozed from the wound, not unfrequently appearing in the form of a great thick band, reaching from the wound to the surface of the soil around the tree. When a tree is felled, the stump bleed in a like manner until large masses of gum can be broken off from the stump. This "young" gum is white in colour, and has not the rich amber colour which age imparts to it when stored beneath the surface of the soil away from the action of sun and weather.

The gum is not soluble in water. It ignites freely, and burns with a lively sooty flame. It froths and bubbles, and produces a pleasant aromatic odour. The perfume it exhales when burning in the open air is not unlike that of frankincense and myrrh.

Some of the finer specimens of kauri gum are used in the manufacture of jewelery, but, while it is very clear and beautiful, it is not so desirable for this purpose as amber. It is not nearly so hard as the latter, and it is much more brittle, and insects and plants are not so frequently found imbedded in it.

Kauri gum was known to the native race long before the island were settled by Europeans. They used it for the purpose of kindling their fires, and it is also said to have been employed by them in their religious rites, but there does not appear to be any ground for the statement Kauri gum became an article of commerce immediately after New Zealand became a British colony. At first the exports were small, amounting to about 100 tons per annum. The price of gum at that time ranged from £5 2s. to £5 19s. per ton The natives then were the only persons engaged in searching for it and bringing it to market.

The implements used in digging for the gum consists of a spade and a spear. The spear is a long steel rod, about half an inch in diameter with a wooden handle with a cross on the top, like that of a spade or a shovel. The rod is brought to a point, and the gum digger pieces it into the ground. Practice and experience enable him to tell whether he is touching a stone or a piece of gum When he touches the gum he digs around it until it is extricated, and then renews the search as before. The number of persons regularly engaged in digging gum varies from 1,800 to 3,000, the greater part of whom are Maories, but even they do not show any special fondness for the work. They resort to it when they become pressed for food and clothing on account of the failure of their crops, or other causes. Many Europeans have resorted to this kind of work, but they belong generally to a class who are unruly and impatient of the restraints which a civilised life imposes upon them, and who prefer to camp out after the fashion of gipsies, and live in tents and raupo huts rather than in houses fitted for civilised beings It is generally supposed that a European who resorts to gum-digging is unfitted for any other occupation He leads a reckless, dare-devil sort of life, away from friends and kindred, and from the restraints of civilisation.

When the gum is taken out of the ground, it is covered with earth, and its surface is found to be in a partial state of decay. When the digger is tired of work, he puts his gum into a bag and carries it to his tent or hut, and in the evening or upon rainy days he, with the assistance of his wife and children, scrapes off the decayed surface until the clear solid gum beneath is reached. When a sufficient quantity of it has been

scraped, it is put into a box or bag and taken to the nearest store or public house, where it is sold for what it will bring. Sometimes the purchaser will assort it, but it is not generally sorted till it reaches the city buyer, who employs a large number of skilled hands for that purpose. The gum, after it is scraped and assorted, is packed carefully in boxes, so as to prevent the lumps from breaking. It is then ready for export. The dust and scrapings are also exported.

Some of the gum is used in New Zealand for the manufacture of varnish, but in no great quantity. The export of kauri gum for the year 1880 is larger than that of any other year. The total export for 1878 was 3,410 tons, and 3,247 tons was the total export for 1879. The invoices thus far received indicate that the total shipment for the year 1880 will be 5,500 tons. The price of gum ranges, according to the *Scientific American*, from 144 dols. to 720 dols per ton. The greater part of it, however, is bought at the former price. The average price may be safely set down at 216 dols. per ton. At this rate the total value of the estimated shipment for the year 1880, *viz*, 5,500 tons, would be 1,188,000 dols. More than two-thirds of the gum goes to the United States It is either shipped to New York and Boston in sailing vessels, or to London for trans-shipment to the American cities.

It is a matter of regret, adds Mr. Griffin, that the kauri forests are disappearing. The trees are being so rapidly cut down that they will soon cease to exist. The Government has not taken any steps to protect them, either by conserving those that remain, or by planting new ones. At the present rate of consumption, fifty or eighty years will see the bulk of the kauri trees cut down. Of course, when the trees are destroyed there can be no deposits, and kauri gum will become a thing of the past The amount of gum taken out of the soil up to the present time has been so great, Mr. Griffin concludes, that it would probably require a forest growth of ten thousand years to replace it.

SELECTIONS.

A VISIT TO THE MOACH SALT WORKS.

A REFERRED has furnished us with the following interesting communication as to the Sind salt works at the Moach.

Above two years have elapsed since Government took up the monopoly of salt manufacture and started an establishment at the Moach, a place of little importance at one time when natives worked on their own account, but now well worth a visit. It would repay the trouble of the trip which is not expensive and is much more instructive than a visit to that "Old Lion of Sind Mugger pier"—a place more distant with worse roads to get over and only horrible sights to see when there, while a trip to the salt works may be heartily enjoyed even at this season with boating, oystering, fishing, &c. &c., and I added on a recent visit at least 2 species of Crustacea to those already on record as occurring in Sind and last and not the least the going over the salt works was time not unprofitably spent.

The Acting Superintendent very kindly conducted me over the entire ground, and great credit is due for the extreme cleanliness of the place and the admirable order in which everything appears to be kept.

The ride to the works from Kurrachee is very pleasant, especially in the early morning, or at about 5 in the afternoon. There is not much to be seen, it is true by the ordinary observer, who would probably discern no more than a great blank in the features of the land but there are many points of interest nevertheless particularly when *nolens volens* carried out of the usual track by a restive camel, by no means a "respector of persons," which has the greatest aversion to wheeled vehicles, gibbing at all he meets, and only to be forced to the object at the risk of his nose, and probably your legs Those who would care to see the Moach Salt works would do well also to make a wide detour to windward of the Municipal sweeping heaps and the Hindoo burning ground, if they have any respect for their old factory system Over beyond the latter the road leads straight to the works which can be seen from a great distance, the hillocks of snowy white salt being very visible. A good cart road also runs up.

The nature of the country adjoining which the manufacture of salt is carried on, may be described as being an extensive plain of saline soil lying near the sea, and running along a stretch of a large marshy creek, with here and there slight undulations, and beyond this bounded by rough stony ground on which the only vegetation to be seen is the euphorbia, commonly called cactus in Sind, and some saline shrubs as *Salsola Sindæ*, &c., &c. Animal life occurs just now in the unpleasant shape of locusts (*Gryllus migratorius*) in their third stage with wings now ¼ of an inch long, and which should now be destroyed, the Rock Lizard (*Uromastix Hardwickii*), and a *Stellio*, hitherto only known in S Afghanistan In some places in the immediate neighbourhood, however, where the soil is less impregnated with salt, small cornfields may be seen which relieve the eye somewhat by their welcome verdure. At different parts where the spring tides flood the low lying land, pretty extensive salt swamps are formed; which, after the tide has receded produce large quantities of what is known as "spontaneous salt." It is on soil of similar kind bordering the "back water," or creek which supplies water indirectly to the pans, that the manufacture by solar evaporation is carried on. The soil is a description of black clayey earth, with an admixture of sand, and is impregnated with salt. There are in all I am informed 51 pans, each divided into from 12 to 23 beds, and having as a source of supply a shallow well 12 to 14 feet deep in its midst, the water being supplied in the most primitive fashion, *viz.*, by a long bamboo lever with a bucket attached at the end, like the *dinrah* of the *fellahs* in Egypt. The extent of land taken up by the pans I have not ascertained; but it is possible to increase it almost indefinitely, as the land stretching along this black water appears particularly suited for the production of salt; in fact, it could produce nothing else, except mangroves.

The process of manufacture, although simple, is not uninteresting. Prior to forming the pans, much preliminary labour is necessary in the way of raising embankments, damming beds and making foundations by treading down the first 2 or 3 yields of salt to make the soil of a proper consistency. This accomplished, the yield continues, and may be worked, for some time, with such slight repairs as become necessary from the action of "raking." The first charge of water usually requires from a week to ten days or more to evaporate, and subsequent ones about one half the time; but the usual run at the Moach is 3 days—much however depending on the season of the year The strength of the brine is tested by the hydrometer; but a more simple means of judging is the reddish tint given to the water by a minute infusoria a species of volvox, which makes its appearance in myriads just as the salt is ready to crystallize This creature is present even in rock—salt, which it tints of a fine pinkish hue, and also in the waters of our sea shore; and is especially abundant in some parts of the Red Sea. This is however a digression. The process of manufacture is the time-honoured one followed nearly throughout India wherever salt is made The 51 pans are, as I said before, divided into beds of greater or less extent to the number of from 12 to 18. These divisions are made by raised ledges about 8 inches high. The salt water is bucketed into the pan from the wells, and the openings closed as soon as all are filled Behind each pan is a second store of water undergoing concentration, which is admitted as occasion requires, into the beds. Here the brine remains till the salt crystals form, but is never allowed to evaporate to dryness. While still moist the salt which has crystalized into the pans to the depth of an inch or two is raked up in little heaps in each bed and previous to being placed in larger heaps for examination, is washed beautifully white. Each heap when completed is stamped all over to prevent fraud, till ready to be taken over by Government—the manufacturers being paid by the outturn—when it is pierced in different places to ascertain the uniformness of quality throughout, the heap weighed, and finally finds its place in some one of the hillocks of salt, standing on raised platforms. Here all the salt manufactured is stored, and here purchasers are served.

There are no roads near the pans passable for carts. Camels only are employed for carriage. The situation of the Superintendent's quarters is good, and there are effective measures adopted for the prevention of smuggling. All spontaneous salt in the neighbourhood is destroyed in the interest of Government.

Of the quality of the Salt manufactured at the Moach, there can be no question as to its being of the best. It is pure and medium grained, and contains a large preponderance of chloride of sodium. From 3 samples obtained in the Bazaar of Moach manufactured salt, the following has been deduced as the average composition :—

Moisture.	6 2900
Insoluble matter	1·6000
Chloride of sodium (salt proper) ...	90 0750
Of magnesium (Epsom salts) ...	1 11,4
, of Calcium	·0985
Sulphate of lime	2682
	99·4771

If moisture be excluded, the percentage of chloride of sodium equals 96 82

It is evident the Government are alive to the importance of the manufacture at the Moach, as I see *pucca* buildings for the establishment are being erected; but how long they will be in course of completion is a question, as the P. W. D. I believe have them in hand.—*C. & M. Gazette, Sinde Issue.*

INDIAN AGRICULTURAL REFORM.

THERE probably never was a time since our first occupation of Indian soil when an exhaustive inquiry into and consideration of the economical condition of the country were so much needed as now. The deficiences in the last budget viewed in conjunction with a financial position of almost normal precariousness, the uneasiness caused by forebodings of increasing national destitution, which, even if we discredit them, we are unable to disprove suggest the need for inquiry and action. On the other hand, if the situation is critical, the opportunities are favourable. The cyclic period of famine or scarcity is past, the empire is at peace, and a party whose special traditions are those of economical government is in power. Only it is to creation rather than to destruction that we must look for help; to an enlargement of our resources rather than to a curtailment of our expenses. Few attempts at thorough agricultural reform have been made in India. The first genuine effort dates from 1871, when India had the advantage of being ruled by a Governor-General who had farmed for his own livelihood, and who was conversant with the theory and practice of modern agriculture. Lord Mayo's endeavours were directed towards the establishment of a real working agricultural department presided over by a Director-General who, with the aid of provincial directors and experts, was to move about generally, while the crops were on the ground, watch closely all local schemes and experiments, furnish suggestions, information and advice, procure through the agricultural societies of Europe and America, seeds, cattle, sheep, models of implements, and keep all fully informed, through the medium of an agricultural journal, of what the rest were doing.

It is not our object to trace the history of this department, though under the invaluable direction of its first and only Secretary, Mr. A. O. Hume,

C.B., it did a vast amount of useful work which has been briefly described in a pamphlet recently issued by that gentleman entitled, "Agricultural Reform in India." We would rather draw attention to a few of the more pressing needs of Indian agriculture, which are dwelt upon in that work, and consider their practicability at the present time. And in treating of these matters it is necessary to award full credit to the natives for the results achieved under their, so to speak, rule-of-thumb system. Considering their ignorance of scientific methods and want of capital, Mr. Hume remarks that the crops they do produce are on the whole surprising. They know to a day when it is best (if only meteorological conditions permit) to sow each staple and each variety that is grown in their neighbourhood; they know the evils of banks and hedges, dwarfing the crops on either side and harbouring vermin; they accurately distinguish every variety of soil, and so far as the crops they grow are concerned, the varying properties and capacities of each, they fully realize the value, though they can command but little of ordinary manure, ashes, and the like. They know the advantages of ploughing in most cases as deep as their imperfect implements and feeble teams will permit, and of thoroughly pulverizing the soil, and they also recognize where, with a scanty or no supply of manure, it would be folly to break the shallow-lying pan; while as for weeds, their wheat fields would in Mr. Hume's opinion shame ninety-nine hundredths of those in Europe. As far as circumstances and poverty will permit, they know the benefit of and practise, rotation of crops, and they are great adepts in storing grain, which they will turn out of rough earthen pits, after 20 years lapse, absolutely uninjured.

But excellent as this non-scientific agriculture is, as far as it goes it must not be overrated. It is wholly empirical; and imperfect appliances, money troubles, the usurer's impatience, and above all, superstition and reverence for omens often prevent the Indian cultivators from practising what they do know. And though the British Government are sole or part proprietors of the major part of the land, they have neglected to carry out any substantial improvements in this primitive system of agriculture which was stereotyped two thousand years ago, when the conditions and requirements of the country were utterly unlike what they are now. With proper manuring and proper tillage, Mr. Hume points out, speaking broadly that every acre of land in the country can be made to yield from 30 to 70 per cent. more of every kind of crops than it at present produces—a fact satisfactorily proved by his own experiments with almost every common North-West Provinces crop, and by Mr. Robertson with most of the Southern Indian staples. But notwithstanding this, and the enormous additional areas brought under cultivation, vast irrigation schemes, and improved and really excellent systems of settlement, the land revenue of the chief provinces of India has actually decreased. A remarkable proof of this will be found in Mr. Clements Markham's "introductory Life of Akbar," recently published by Allen & Co. In the reign of that monarch, the land revenue of India (less Cabul, which now belongs to Afghanistan, and Madras and half Bombay, which were outside Akbar's dominion) amounted, under an admirable system of settlement, to £15,775,838, while the amount of land revenue derived by our Government in 1877 from the same provinces was only £13,356,248. When we reflect on this and on the fact that the agricultural masses are, to say the least neither wealthier nor better fed, taking the country as a whole, than they were 70 years ago, we need seek for no more convincing proof of the fact that if good government consists in doing the best one can for the land and its inhabitants, ours amounts to a very serious failure.

The sole explanation of this state of things is that the older-tilled lands as a body yield now lighter crops than they formerly did. This is the reason confidently assigned by Mr Hume, and he adds that it is what almost every experienced and intelligent cultivator in Upper India will say is the fact in regard to all but that little circle of fields skirting each inhabited site which gets the great bulk of what little manure is available. And what is it that has brought about this disastrous condition of affairs? Speaking broadly, it may be said to be due to a system of quasi-spoliation, the continually taking a great deal from the soil and putting very little back. But the disease may be subjected to a closer diagnosis. Only 50 years ago, when jungles and grazing grounds abounded, when cattle were more numerous, when much wood was available as fuel, there was actually a much greater amount of manure available, and a very much smaller number of fields on which to spread it. But of late years the stock of cattle has sustained incredible losses from starvation and different forms of cattle disease, and the consumption of their droppings as fuel is due to the impossibility in some places, or expense in others, of procuring wood. For six weeks every year the cattle are practically starved over a greater part of India. Mr. Hume's description of the hot season is so graphic that we cannot forbear reproducing it :—

"The hot winds roar, every green thing has disappeared, no hot-weather forage is grown, the last year's fodder has generally been consumed in keeping the well bullocks on their legs during the irrigation of the spring crops, and all the husbandman can do is just to keep his poor brutes alive on the chopped leaves of the few trees and shrubs he has access to, the roots of grass and herbs that he digs out of the hedges of the fields and the like. In good years he just succeeds; in bad years the weakly ones die of starvation. But then come the rains. Within the week, as though by magic, the burning sands are carpeted with rank, luscious herbage, the cattle will eat and over-eat, and millions die of one form or other of cattle disease, springing out of this starvation, followed by sudden repletion with rank, juicy, innutritive herbage."

The enormous annual loss of cattle in India was a matter which received Mr. Hume's attention in connexion with a scheme of Lord Mayo's to establish veterinary colleges in the Bengal Presidency. Diseases of the most virulent character, plagues, and murrains had raged unchecked amid agricultural stock, and devastated whole districts, depriving millions of their savings and means of subsistence, and seriously endangering the food-supply of the country. But a few years ago more than half the cattle in Oude were lost during two successive bad seasons. The average annual value of the cattle lost in India by preventible cattle disease of one form or another is estimated by Mr. Hume at £7,500,000, and this in climates where, if the beasts are moderately fed, given plenty of work, and kept away from contagion, they never seem to be sick or sorry, but are very prolific, and work on from youth to extreme old age.

Besides the loss of cattle, another source of ruin is to be found in the occurrence of *reh*, or saline efflorescence, in irrigated lands. This evil, though still imperfectly understood, is one of increasing magnitude. Along the Western Jumna Canal thousands of fields are to be seen lying barren and glittering as though hoar-frost were overspreading the land, an efflorescence due to the excess of soluble salts, which, as the water which has sought them out works upwards by capillary attraction and dissolves in vapour, is left as a sterlizing deposit on the face of the earth. The general remedy for this serious evil, it is now beginning to be admitted, is subsoil drainage, by which the excess of saline matters may be passed away. But, inasmuch as the efflorescence is one of complex origin and constitution, very different additions to the soil, organic or mineral, may be necessary to enable it to seize the *maximum* share of the utilizable portions of the *reh* as it is filtered downwards. Herein is another important practical investigation which scientific agriculture alone can satisfactorily undertake.

A very important matter which might with advantage occupy the attention of a department of Agriculture is the provision of some general growth of hot-weather forage, which will not require much good land, irrigation, or capital, for all these are difficult to get. This is not so impracticable a matter as it sounds. In India, wherever you have a closed grove of trees, there you have a spontaneous and luxuriant growth of herbage, and at the end of April, even in the hottest and driest parts of Upper India, while the whole country round is as bare as any desert, there will be found in preserved groves (such as the more wealthy zemindars often keep) a mass of hay above and green grass below that is perfectly surprising. This is due partly to the rich deposit of decayed twigs and leaves and partly to the diminished evaporation from the soil, protected by the trees. By planting communal groves of this character throughout the country a most important benefit would be conferred on the inhabitants. Together with a valuable provision of fodder would be obtained an improved supply of fuel, and an immediate great diminution in the consumption of manure for such purpose. The resulting good would thus act and re-act in many ways. To achieve this object it would be necessary to select a tract of land in each village which would be good enough for planting with hardy trees, but yet too poor to be worth cultivating, obtain legal enactment for its being set apart for the communal purpose referred to and impound the services of the villagers for breaking up the ground, planting it and surrounding with a good stout mud fence, the enclosure after a few years being thrown open to the cattle in the hot season. Such an undertaking would, as Mr. Hume remarks, undoubtedly be vast, but there could be no possible objection to an experimental and partial trial of it in any selected localities, and its beneficial outcome would be manifold and permanent.

The list of subjects which would fall to the notice of an Agricultural Department is, from the circumstances of the case, a long one. One feels tempted to dwell on the improvement of which the rude native mechanical appliances are susceptible, the utilization of undeveloped products (such, for instance, as the numerous fibres indigenous to India and adapted for a supply of paper-making stock), the improvement in the breeds of cattle, and a score of other important and pressing needs. We have, however, cited enough to indicate that the reforms which await attention in India, have the closest and most vital bearing on the economic condition and wealth of the country, and that some agency for their due discharge is imperatively called for. The Indian Agricultural Department suffered a practical abolition when the late Viceroy amalgamated it with the Home Department, and discharged its exceptionally gifted chief. All prospects of achieving any great agricultural reform was thus, for a time, effectually shut out. It may, however, be not too much now to hope that the present Governor-General may see his way to carry into practice tentatively some such project as Lord Mayo planned. Its results and teaching could not but be valuable and instructive, and under competent direction they might be successful enough to earn him the thanks of all posterity.—*Times.*

THE CULTIVATION OF BEET.

THE cultivation of beet occupies a large amount of public attention. France produces about one-fifth of the total European yield. About 5 per cent. of sugar is obtained from roots grown in this country, while in Germany and Austria, the return varies from 8¼ to 8½ per cent. The reason of this difference is due to the French farmer aiming at once to secure roots that will simultaneously repay the sugar manufacturer, the distiller, and the stock fattener. Large roots are the terror of fabricants, which growers complain that the factories do not offer prices

to encourage the raising of smaller-sized ones. In Belgium, agriculturists assert they are ruined by accepting the seed supplied by the factory proprietors; however, there can be a serious difference in the richness of a variety of beet as much even as 6½ per cent. The aim in sugar beet culture is to plant in narrow lines, moderately manure, secure a root about 2lbs. weight, globular, not growing much above ground, with few roots, and hence easy to lift and subsequently manipulate. Of the prospects of this season's crop sowings are late, and vegetation three weeks in arrears. The advantage, however, is clearly in favor of early sowings so far. Another moot point, now occupying prominent attention, is what is the best base for determining the commercial richness of beet? The majority advocate selling according to density; but Professor Petermann of Belgium leans to the system of saccharine richness. In the former plan, the better theoretically for all interested, the chief difficulty lies in its application. M. Pagnoul, an authority in the dispute, lays down a juice density scale, commencing at 4·5 degrees, and rising by one-tenths to 7. A density of five degrees, would represent a saccharine richness of 9·5 per cent., and a yield per acre of 20 tons, at the price of fr. 16 per ton.: A density of 7 degrees, 15 per cent. of sugar, a return of 18 tons per acre at a price of fr. 38 per ton, being a monetary difference in favor of the latter, of fr. 94 per acre. A juice of a density below 5 degrees becomes unremunerative, not only containing less sugar, but more foreign matter detrimental to the extraction of the sugar. The density could be estimated by having an independent official at the factories, who would determine it from half-a-dozen of average sized roots, three to be selected by the fabricant, and three by the farmer. Some agriculturists, in order to increase the density of the juice, have recourse to the fraudulent plan of applying nitrates to the beet during the last stage of its growth. This induces fresh vegetation, the root augments and also the leaves, but at the expense of the sugar in the tissue of the roots, so that the density which was 5 degrees falls to four, and the fabricants quickly discover the fraud. M. Pagnoul advocates the raising of eleven beet roots to the square yard, each root to weigh about 14 ounces, and the yield per acre to be 16 tons. A ton of beet carries off from the soil 18lbs. of alkaline salts. Manures for beet ought to be of a nature to be rapidly assimilated, capable of acting at the commencement and middle state of the plant's growth, during the period when light is strongest and longest, and so more favorable for the production of sugar. A slowly acting manure, produces the same effect on the roots as the fraudulent application of nitrates just described. To avoid such a result, German farmers apply farm-yard manure to the preceding crop, employing a limited dose of nitrate of soda and superphosphate, following the wants of the soil, before sowing. All that tends to produce a rapidly developing root can only be favorable to its saccharine qualities.—*Madras Mail.*

THE DATE PALM.

THE wild original of the Date Palm is not known with certainty. Some writers regard *Phœnix spinosa* as the wild form from which it has descended, whilst others would trace it to *P. sylvestris*. Fischer does not mention the latter species, which inhabits the warmer parts of India; but he combats the view that the former can be the parent of the cultivated date, because its distribution affords proof of a totally different constitution. It inhabits tropical Africa, and is restricted to regions enjoying copious rain. Our author agrees with Cosson that it is far more probable that the progenitor of the Date Palm was a native of the extra-tropical desert region, the strongest evidence in favor of this being a record that it existed in a wild state in the Canary Islands anterior to their settlement. This record has been in a measure confirmed by Bourgeau's explorations. Nevertheless, it is noteworthy that both of the species of *Phœnix* mentioned closely resemble the date, especially when the latter has run wild, yet they do not overlap the date in their distribution. *P. sylvestris* is one of the commonest plants in India, but it ceases growing where *P. dactylifera* is cultivated or has run wild. A peculiarity of the latter is to produce suckers in abundance, both under cultivation and in a wild condition; and left to itself it forms impenetrable thickets. The lofty columnar trunk surmounted by an ample crown of feathery leaves with pendent heavy golden or red clusters of dates, is a product of art, not of Nature, for the leaves naturally persist and conceal the grace and elegance of the tree. The true date exists in a wild state in many places throughout its cultivated area. Roughly this area may be described as the extra tropical rainless and slightly rainy region of North Africa, from the Atlantic to Egypt, and through Arabia, Persia, and Afghanistan, to the Punjab in India. This zone lies between the 15th and 35th parallels of latitude. It is also cultivated in some situations in Southern Europe, where the climatal conditions are similar. We have not sufficient space to enter into the history of the cultivation of the date, and the impress it has left on the works of the ancients; but we may recall the massive pillars in the ruins of Edfoo (Apollinopolis Magna) surmounted by gigantic capitals, about 7 yards in circumference, faithfully representing the crown of foliage.

OASIS.—The date palm alone preserves, and to a great extent constitutes these small isolated spots of vegetation characteristic of the wide, wide Sahara. In their figurative language, the Arabs say "this King of the Oasis plunges its feet into water, and its head into the fire of heaven." This pretty accurately describes the conditions under which it flourishes best. Where the atmosphere is humid or the rainfall considerable, there the date palm will not ripen its fruit. Cosson (*Le Regne Végétal en Algérie*, p. 58) states that if there is such a thing as an oasis in Europe, it is at Elche in Valencia, where there is a plantation of 60,000 date palms ripening their fruit. Under the shade of the date, cereals and many other plants are cultivated.

CULTIVATION.—Abundant moisture at the roots, great heat at least during the summer, much sunshine and the little rainfall, are the most essential conditions in the cultivation of the date. Neither the fiercest heat of the sun nor the strongest winds injure its foliage. The wind may bend the crown to the earth, or even uproot the tree, but it is incapable of breaking its trunk, and it will bear without injury 10 deg. or 12 deg. of frost, as well as very low night temperatures succeeding very high day temperatures. The nature of the soil is of little importance, provided always there is plenty of water, which may be either fresh or brackish. Like most of our fruit trees that have been long under cultivation, the date palm has given birth to innumerable varieties, and these increase in number as we recede from either the Polar or Equatorial limit of its cultivation, whereas only two are distinguished at Elche in Spain, and Thebes in Persia. Cosson enumerates seventy-five for the Oasis of Zibau. These varieties differ in the consistence, shape, colour, and ripening season of the fruit, and they bear such names as the beauty of Mimon, the Gazelle's Horn, Dove's Egg, Bird's Brain, Bitter-sweet, Sweetness Itself, &c. Propagation is usually effected by means of suckers as they not only perpetuate the variety pure, but come into bearing much younger, and the cultivator runs no risk of over-production of the male plants. In five years they produce fruit, though they do not come into full bearing until they are about thirty years old. After they attain eighty or ninety years, the crop begins to diminish, yet they sometimes continue bearing until they are 200 years old. The trunk is of very slow growth, and eventually reaches a height of 70 or 80 feet. An old tree that produces fruit of a superior quality is sometimes rejuvenated by banking up the trunk with mud to a depth of two yards. In about a year's time it is rooted in the mud; it is then cut off above the old roots and transplanted.

DESTRUCTION OF DATE GROVES.—Generally speaking the destruction of a tree is regarded as a sinful act, and the most deplorable results have followed the cutting down of the enemy's date palms in warfare. Extensive areas have been thereby rendered permanently desolate.

IMPORTANCE OF THE FRUIT.—Although the inhabitants of the desert subsist for long periods almost or quite upon dates, yet these do not replace every other article of diet as the cocoa-nut does in some regions. They may replace milk, fish, and meat, but grain is regarded as a necessary concomitant. Dates are prepared for eating in a variety of ways. An Arabian proverb says that a good housewife knows how to dish her husband up dates differently every day for a month. Animals as well as human beings draw a great part of their nourishment from dates—the seeds are given to animals. Fresh fruit is very largely consumed, and may be had for several months in the year in the most favourable situations, but immense quantities are dried and stored, and if properly done will keep good for years. It is estimated that many millions of persons derive the greater part of their nourishment from the date palm, and by far the greater part are inhabitants of extratropical regions.

INDIAN HONEY.

IN England the cultivation of bees has attained extraordinary perfection, and every year we have a Honey Show, where the latest improvements in hives, and the largest specimens of combs are exhibited, and rewards given according to merit. The poorer class are in this way encouraged to exercise thrift by cultivating the remunerative and easily kept bee. Even in busy London, with its superabundance of lime and brick, and its scant allowance of shrubs and flowers, high up on fifth and sixth storeys bee-hives are kept, and while busy men are hurrying along the street to collect their money, the busy bee is speeding along high in mid-air to collect its honey. Perhaps the reason why in India so little is known of the subject, is that our first acquaintance with the indigenous article is derived from the purchase of a bottle of that noxious liquid sold in beer and brandy bottles as Mahableshwur honey. It looks like castor-oil in the crude state and tastes, partly like it, and partly, perhaps, like *jagree* or molasses flavoured with onion. I eschew "Mahableshwur honey."

The bee has in all ages carried off the palm as an example to man. Its praises have been sung by poets and philosphers for its industry, intelligence, thrift, forethought, &c., and Dr. Watts has made us familiar with its habit of improving each shining hour. Solomon has referred the sluggard to the ant if he wishes to mend his ways, but I think he might almost as well have referred him to the bee, unless it be for this reason that the bee is altogether dependent on "shining hours." Wet and cold put a complete stop to his operations. I must not, however, dwell longer on these commonplaces, except to say that I believe the government of a hive is not a commonwealth but a monarchy. The queen is a sovereign in every sense of the word. She is continually followed by her body-guard, and the deference shown her by the other bees shows that they at least do not think one bee as good as another. The citizens, it is true, work for the good of the State, as it was in the palmy days of Rome,

the queen is the dictator. There is no republic in Nature. Neither shall I go over such points in bee economy as are the same among English and Indian bees. If any one wishes to be informed on these points, any book on bees will enlighten him. I shall only refer to "things not generally known" about the three common kinds of honey bees to be found in that ubiquitous portion of India known as Dustypore. Two of these kinds are in some parts of the country not uncommon, and may be called the big and small honey bee. The big bee very closely resembles its English contemporary in colour and appearance, but he is nearly half as large again, and his disposition is totally different. He is active and fierce, and his sting is far more formidable, so that no one can any approach his hive with impunity. He is not to be meddled, with—no, not for a moment. Fortunately for us men, his hive is usually "situate" aloft on the underside of some high rock, or public building like the Rajabhai tower, or if it be a woody country, on the branch of some large tree so that there is little danger of disturbing a swarm, and nothing is to be feared from a solitary bee. Woe betide the man, however, who unwittingly lights a fire under such a tree, for the smoke, as it "gracefully curls" upwards, will soon bring down the whole army, and they will execute terrible vengeance. I once saw a swarm of, I suppose 20,000, seeking for suitable spot to settle on, and as they buzzed round and inspected the head of my ghorawalla, he angrily struck one to the ground. In a moment news of the outrage was communicated to the others, and half-a-dozen stings were buried deep in his face and arms. This premonition saved him, for he fled howling to his tent, and managed to close the doors just in time to keep out the whole swarm which came hotly pursuing after him. On the principle of "love me love my dog," the infuriated bees then fell upon his innocent horses and though the beasts rolled on their backs, killing hundreds every minute, the dark cloud which hung over them never seemed to diminish. It was not till they got rid of their ropes that they were able to escape from their persecutors by galloping over the plains. I do not see why the honey of these bees should not be obtainable by carefully protecting all one's vulnerable parts, and then climbing boldly up to the hive and cutting it down; and if the hive be in an accessible place, the bees may easily be driven off with fire and smoke at night. The natives, however, in most parts of the country, much as they love sweets, scarcely seem to be aware that the hives cont in honey, but avoid them with a kind of horror. It is only where honey is sufficiently common to make trade in the article profitable, that a class of men springs up whose "business" it is to collect it. The ordinary Hindoo will not be tempted into trying dangerous experiments. Who knows what might become of him! I must not forget to mention that it is a merciful provision of Nature to compensate poor distressed bee-stung humanity, that whenever a bee stings a man, the sting comes off, and as the bee cannot live without its sting, it soon dies. We may therefore whenever a bee stings us, always soothe ourselves with the thought that we have killed the bee.

The comb of this bee, when finished, is about three feet in length and about two and-a-half in depth, and the cells are back to back, as in English hives. Only the honey is always storted in the cells at the top round the branch, and the lower cells beneath the branch are devoted to the larvæ, so that it is an easy matter to separate the honey. This is the form adopted by all the three kinds of bees I have referred to. The bees never use the same cells for different purposes. The big bees make a prodigious quantity of honey, but owing to the dangerous character of the insect my information is limited, and I have never measured the produce in quarts.

I have a much greater affection for the little bee than for the big savage monster. He is an inoffensive little thing, scarcely larger than a table fly, and those who have gardens must have seen him often murmuring among the flowers and collecting his treasure with his little woolly feet. Moreover, his sting will not penetrate the human skin, and he is always drowsy, and never seems to have his wits about him. In fact, on a cold weather morning, he cannot be got to move at all. I think if experiments in keeping bees will succeed in India at all, this is the kind that would prove most practicable. The hive is generally in a thick bush or hedgerow near the garden. Not, however, because the bees like our flowers. On the contrary, showy flowers, and above all double flowers, are their abhorrence. The bee may patronise some of our flowers, but it is the little, highly-spiced aromatic, pollen-producing wild flower that is his favourite. He seeks the haunts of men only because in a well-watered region he can get his supplies within a limited area, and that is what he wants. He cannot, like the big bee, secure miles of country. The comb of this bee is at its largest only eight or nine inches in length, and the greatest quantity of honey I have ever found in one was three-quarters of a pound.

The third variety of bee which I mean to describe is not to be distinguished from the last in appearance; nevertheless, there is one important difference, namely, that it is possessed of rather a formidab'e sting. It is possible that the sting is only a development which the honey-eating propensities of Englishmen have rendered necessary to prevent the race being exterminated; but as Englishmen know nothing about these bees, I am inclined to think this bee is a distinct species, and its close resemblance to the other species is only intended to create an occasional pleasant surprise among honey-eaters in general. I once had such a pleasant surprise. One fine morning, while out walking, I spied, some yards from the ground, in the overhanging branches of a [illegible] tree, a small bee-hive. I quickly scrambled up the trunk of the tree, and crept along the branches to the hive. Then taking out my knife, I pushed aside the bees to see what was the amount of honey. Before I could cry 'Jack Robinson,' several bees shot out from the hive, and made "remarks" on my face which made me retreat precipitately among the leaves. Luckily, leaves afford a complete protection from bees, and while the wretches were thinking they had routed me with great slaughter, I was already meditating fresh schemes for revenge. I left as I had come, and next morning returned again better prepared. First of all I ascended the tree, and with a small saw quietly cut through the branch at some distance from the hive. The branch was borne up by several others around it, so I did not disturb the bees. I then tied a string to the branch, and threw one end to the ground. I then descended, and put on my armour, which consisted of a muslin bag put over my head and tied at the neck, and a pair of gloves. I also tied my sleeves at the wrists and my pants at the feet, lest perchance the bees might travel down them and turn the corner. All being ready, I took hold of my string, and with one ferocious pull brought down branch and hive. In an instant, the bees guessing that my face was the most vulnerable part, came down like a cloud on the muslin. Had the onslaught been as persistent as it was fierce, I have little doubt they would have discovered joints in my harness, but fortunately for me, as soon as they found their stings ineffective, they beat a retreat. When I felt assured of my safety, I removed my gear, and found the comb uninjured, with scarcely a bee left. I bore it home in triumph to discuss at my leisure, and the honey was almost the best I have ever tasted. The honey of the big bee is no doubt stronger and more worth having than that of the others, but what affects the quality of the article more than anything else is the flowers from which it is gathered, and wild flowers are the best. The honey of the little bee varies so much, that it is sometimes, like sugar and water, and at others almost equal to the best English honey.

Just one point more before I close, which may interest naturalists. All these kinds of bees first make their appearance about the beginning of October, and continue their work till May. This honey is not stored up for the use of the old bees in winter, but is a sort of "pick-me-up" for the young ones, and as each young bee breaks the covering of its cell and issues forth, its first act is to climb to the cells at the top of the hive and take a long draught of honey. After taking this draught it is soon ready to commence business itself, but without it it soon dies. The young bees come out in regular order as the cells have been built, beginning with those nearest the branch, and extending in a semi-circle to the edge of the comb. Whenever a sufficient number of bees has been hatched to form a swarm, they leave the hive on their own account, and the amount of honey is exactly suited to the wants of young bees, so that when the last of the bees is hatched and has taken its initial draught, there is no more honey left. I do not know if one swarm will make two combs during the same season, but by the end of May all the honey is done, and the combs are deserted. What becomes of the bees after that I do not know. It seems not improbable that they pass the wet months in the hollows of trees, but I have never seen this authentically stated.—*Journal of Applied Science.*

AGRICULTURISTS IN CAP AND GOWN.

A SHORT time ago the students of the Madras Agricultural College presented a petition to the Senate of the University of Madras with a prayer that it "would patronise the institution, and take under its fostering wings, a science, the study of which your petitioners submitted was no less important than that of Civil Engineering and Medicine." In other words those who signed the petition wished to be placed on the same footing as other University students. They say :—"That seeing the primary importance which the profession of the husbandman occupies, and must occupy in this country in the face of a rapidly increasing population with the arable area already pushed almost to its extreme limits, your petitioners feel sure that you will think it necessary and desirable that the intellect of the country should be directed to the study of Scientific Agriculture, which *alone* can prevent the results which such a condition must bring about if unchecked. That from the improvement of agriculture, as great benefits will accrue to the people of this country as from the study of Civil Engineering and Medicine which have been patronized by the University. That your petitioners hope that, if the University affiliates to it this institution and grants Degrees in Agriculture, the art now so degraded will rise in the eyes of the people and its true importance as "the most useful, the most noble employment of man" will come to be better recognized. That agriculture is a recognized part of the University curriculum of many American Scotch and German Universities, and that distinct Degrees in agriculture are now granted in some of them."

It must be admitted that there is great truth in what is here said; that agriculture ought to be treated scientifically there can be no doubt, and that it ought to be improved is evident to those who have been any time in the country. It would be better that youths should take a degree in farming than in arts, for in the former case they would help to develop the resources of the country, while in the latter they would only settle down to Government employ. But we question whether the scheme put forward by the students is the best calculated to forward the interests of agriculture; we think that the country is not sufficiently advanced to allow of degrees

being given for this subject. It is true that in American, Scotch, and German Universities such degrees are given, but it must be borne in mind that agriculture is in a very different state in the countries of the west from what it is in India. For many years past Europe and America have been doing their best to make the most of the land and everything has been done to get the greatest amount of possible good out of it. But the case is very different in India, and the farmer here is not able to carry out the suggestions of the scientist. There they do not think that the proper plan is to follow the footsteps of their ancestors; they do not believe that everything is right simply because those before them did it.

Looking at the course of instruction laid down in the Madras Agricultural College, we cannot help thinking that it is far too ambitious in its character; far beyond what is required. We do not say that agriculture should not have a high standing; that it should not eventually be ranked with engineering and medicine, but at the present time something of a simple nature would be sufficient. The education that the youths receive will place them far above the most intelligent ryots, and the result will most probably be that these young men will look down upon the men whom they will be expected to instruct; the ryots will look upon their knowledge as new fangled and unsuited to their wants, and consequently they will reject the instruction that will be given to them. The cultivators will be likely to ask these young men whether they have come to teach their grandmothers to suck eggs, or a similar question in the vernacular. The fact is, to give men a thoroughly scientific—or rather we should say, collegiate—education, and then to send them out among ignorant ryots is something like using razors to cut blocks of granite. It would be better to give the students a less ambitious education in the first place, and then after they had taken their place on the land and taught the ryots the benefit of a superior system of cultivation, the curriculum of instruction might be raised. At the present time it is not so much scientific knowledge that is required as practical improvement, and it is to be feared that the youths who are trained in the College will pay more attention to the former than to the latter; we fancy that they will consider everything that is worth learning is to be obtained in the lecture room, and should the Senate of the University grant the payers of the students and confer degrees in agriculture, we feel sure that the out-door work, by far the most important will be looked upon with great disfavour, and will as far as possible, be neglected.

The petition before us, shows what a hold the University has upon the minds of Indian youths; they seem to imagine that everything that does not lead up to this is worthless; that knowledge that has not the superscription of the University upon it ought to be rejected. This feeling exists to a most unwholesome degree, and the petition before us is a proof of it. The knowledge which the youths who signed the document value most is that which would make them stand the highest in the University list, and in all probability this is the knowledge that would be of the least use to them as agriculturists. We think, after perusing the petition before us, that the Senate of the University instead of granting the prayer of those who signed it would do well to put that institution on a better basis in other respects.—*Bangalore Spectator.*

EFFORTS TO IMPROVE NATIVE HUSBANDRY IN SOUTH INDIA.

(By Wm. Robertson.)

In May 1880, I had the honour to read before the Society of Arts, a paper on "The State of Agriculture in South India." Since then the Indian Famine Commission Report has been issued, and several important papers, embracing many of the subjects dealt with in my paper, have been read before this and other societies. Of course, on such questions some differences of opinion must exist, but, on the whole, the opinions expressed agree generally, with those I ventured to place before you. My conclusions may be summarised regarding South India as follows :—

(a.) The good land is already under tillage: any addition made to the tillage area must therefore consist of inferior soils.

(b.) Additions made to the tillage area must be at the expense of the area that produces scrub-jungle and grass, which afford the ryot—free of cost—fuel for domestic use, and grazing for his stock, which resources thereby become lessened.

(c.) The addition of large areas of poor soils to the area under tillage, increases the necessity for applying manure, while the corresponding decrease in the area yielding fuel and grazing, diminishes the ryot's means of supplying this manure.

(d.) The proportion of the occupied area, cropped annually, is considerably greater now than at any previous period, thus the benefiting influences of "fallowing" are less exercised.

(e.) Half-tilled, unmanured, arable land, bare for six months in the year, is much less able to retain and store the rainfall than the land when under scrub-jungle; the rain-water flows more quickly off the land into the beds of streams, and the irrigation sources dry up sooner in the season.

(f.) There is, generally, a great waste of irrigation water; were the water used with care, the irrigable area might be largely increased.

(g.) Famines occur during long periods of drought, when the crops cannot obtain the water they require.

(h.) The half million persons added yearly to the population of the presidency, rely for food chiefly on crops raised on inferior soils, farmed without the aid of irrigation water, and almost without manure.

(i.) Under present conditions, famines are likely to become more frequent and more severe.

(j.) Under good husbandry—by deeper tillage, and by the use of organic manures—the soils might be made much more fertile, and the crops rendered less liable to suffer injury during a moderate drought.

(k.) The welfare of the State depends upon the condition of agriculture even to a greater extent now than formerly, seeing that it has guaranteed to protect the people against the effects of famine.

(l.) A primitive system of husbandry, which sufficed to meet the wants of a scanty population, when there was plenty of good land available, no longer suffices, now that the demand for human food has become so great, and such a large area of poor soil has to be tilled.

Early in the present century, attention was given by the State to the improvement of indigenous varieties of cotton, but nothing on an extensive scale was attempted until about 40 years ago, when the Marquis of Tweeddale was Governor of Madras. A Cotton Department was then organised, and cotton farms were established in various parts of the presidency. These so-called farms. I should explain, were mere tracks of land, frequently unfenced, and generally without any buildings. The land was devoted exclusively to the culture of cotton. On these farms, crops of Bourbon, Egyptian, and New Orleans cotton were grown from imported seed, and the seed produced was distributed over the presidency; but the land was devoted chiefly to the culture of the better kinds of indigenous cotton, which, it was thought, might be improved by better culture, the liberal use of suitable manures, the careful selection of the best seed for sowing, &c. These farms were under the direct charge of men who had been brought from America, and who were supposed to possess a thorough knowledge of the cultivation of cotton, and its treatment when undergoing preparation for the market. In connection with these farms, experiments were carried on in ginning and packing cotton for export. These cotton farms were carried on for a short time in the face of many difficulties. Some valuable experiments were carried out, and much important information was collected. But a new Governor having been appointed, who had no interest in agriculture, the partially dormant opposition, which had existed for some time, assumed an active form, and the Cotton Department was eventually suppressed. There can be no doubt whatever that the administration of the department was defective in some important respects. But taking into account the state of agricultural knowledge at that period, the many difficulties to be overcome, and the hostility of the class from whom aid and support might have been hoped for, the experiment was quite as successful as in reason could be expected. It was certainly a mistake to confine the operations of the farms exclusively to cotton culture. Had efforts been made on a similar scale, and with the same persistency, to improve agriculture generally, any improvement secured would have acted for good on cotton culture, and such results thus obtained would have been more lasting in their influence. It was also a decided mistake to improve largely seed of superior varieties of cotton from countries where cotton is grown on fertile, almost virgin soils, or cultivated with skill by intelligent planters, and to attempt to introduce these kinds of cotton at once into general cultivation in South India, on impoverished shallow tilled, unmanured soils. Before superior sorts of cotton can be grown in South India with success, there must be a very great improvement in the character of the husbandry generally practised. In a few favoured localities, in various parts of the country, the conditions necessary for the successful culture of the higher races of the cotton plant can undoubtedly be secured; but the land thus favourably circumstanced is already usually fully utilised.

However, as I have already stated, the Cotton Department effected much good. We have, even now, in certain districts in South India, a variety of cotton introduced and acclimatised by the department, which, though much deteriorated, is still superior to any indigenous cotton; while there can be no doubt that the immense quantity of superior cotton seed distributed over the country has effected much good in indigenous cotton, by inter-breeding with it.

The plea under which the Cotton Department was suppressed, was that the department was not a financial success—that its income did not meet its expenses, as if this was the standard by which the results of the operations conducted were to be judged. I never can understand why in India this standard should be applied only to enterprises having for their object the improvement of agriculture. Were the same standard applied to the results of the working of the various departments of the State, in determining the claims of these departments for continued existence, I fear they would have no better ground to exist longer than had the defunct Cotton Department; while, in this country, that great institution, the South Kensington Museum, which is doing so much for the education of the British public, the equally important institution at Kew, would have to be suppressed were their results judged of by this shop-keeping standard. It is true that the out-come of all successful agricultural enterprise must of necessity, be a gain, but it does not follow that this gain can be made to assume a money form for the State.

Of the many difficulties encountered in conducting the work of the Cotton Department, not the least was the suspicions with which its operations

were viewed by the ryots generally. They could not imagine it possible that a Government, apparently influenced only by ordinary commercial policy, could act, as it were, disinterestedly. In many instances they not only refused the use of their land for the experiments, though a liberal money compensation was offered, but not unfrequently refused to accept, for sowing, superior cotton seed when offered free of all charge. They seemed firmly to believe that the sole object of Government in giving attention to cotton culture, was to get a reason for raising the rent of the land.

After the closing of the Cotton Department, the State withdrew from all active interference in cotton cultivation, and, for some years but little was done by the State in any other direction towards agricultural improvement. A few isolated experiments were conducted here and there under district collectors, notably the late Mr. John Sullivan, who, in the Coimbatore collectorate, conducted many useful agricultural experiments, chiefly in the introduction of new crops on the Nilgiris, then constituting a portion of the Coimbatore district. Amongst other crops he introduced there, was a variety of wheat obtained from South Italy, which at one time was largely cultivated on these hills, and, even now, is grown to some extent there. This gentleman also introduced barley, and several crops now well established on the Nilgiri Hills. But, generally, the experiments conducted by collectors at this period seldom yielded results of a useful nature, not so much from want of knowledge or want of interest on the part of collectors, but from want of leisure to give the experiments the required attention, and from the frequency with which they were transferred to other collectorates.

Agricultural shows have been held in various parts of South India, with a view to the promotion of agricultural improvement. About twenty-five years ago, shows of this nature were frequently held in the different districts. At these shows prizes were offered for good specimens of agricultural stock field produce, agricultural implements, tools, &c. The shows were held at the head-quarters of the collectorates. The prizes were numerous, but small in amount. The average cost of such a show was about £200, the whole of which was provided by Government. In the districts of South India, among a people so backward as are the rural classes there, generally, the holding of agricultural show, could not but be attended with advantage. But the shows were, at first, undoubtedly looked upon with great suspicion by the agricultural classes, The Revenue Board of the Presidency, in referring to one of these provincial shows observed, "The committee at Cuddapah has great difficulties to contend with, and experienced considerable opposition. The show, therefore, can be regarded as having effected little more than dissipated the suspicions and fears of the people." Afterwards, in referring to the results of the first series of these shows, the Board remarked, "The provincial exhibitions, generally, have been as successful as, under all circumstances, could have been expected." About three or four years later (1859), a number of provincial agricultural shows were again held in Madras, fifteen having been held in that year, at a cost of about Rs. 85,000. The results of these shows, appeared to have been considered disappointing, for the Board of Revenue, who again had the control and general management of the shows, thus wrote :—

"On the present occasion, long notice was given, and full publicity ensured. The sum placed by Government at the disposal of the local committee was ample, and liberal prizes were offered for competition. The Board regret, however, to state that, with few exceptions, the result has not been satisfactory. The novelty of the thing has, to a great extent, worn off; the preconceived idea, of the majority of the exhibitors, apparently, that the trouble of producing a specimen was in all cases deserving of reward, without reference to the character of the article, and their corresponding disappointment, the depreciating accounts of unsuccessful competitors, the fear of cholera and, in some instances, the superstitious belief that the unfavourable seasons of late years were to some extent produced by the 'evil eye' of those to whom the produce of their labours was publicly exhibited, have combined to produce this result. The interest, however, of the spectators seems to have been unabated, and that good has resulted from the movement the Board believe. The cultivation of valuable special products has been extended, and in some cases originated—improvements in farming, in cattle breeding, and in implements, have been encouraged, and some acquaintance with the advantages of machinery afforded. Some branches of manufacture, which promise to be valuable, have been developed, especially in fibres, and it may confidently be expected that the seeds of emulation and enterprise that have been sown will bear fruit in the future."

If the results mentioned in the latter part of this quotation were really as stated, I venture to think that these provincial shows were successful, and that they ought to have been continued from year to year.

During the last 20 years, but very little has been done in holding agricultural shows. Two have been held near the City of Madras, and one on the Nilgiris, and one or two in other districts; but none since 1874. In one district, that of Nellore, cattle shows were held for several years in succession; but these also have been discontinued. At the present time, therefore, this highly important means of improving agriculture is altogether unemployed in South India.

In England, with its highly advanced agriculture, we have in every county an agricultural association, and in many counties several district or local agricultural societies, all actively at work in promoting agricultural progress. These associations and societies in the British isles spend annually very little less than half a million pounds sterling; an expenditure which, I think, can be justified on strictly commercial principles, and yet, according to the present Indian official view, such an expenditure would be considered unjustifiable. I am strongly of opinion that agricultural shows should be held annually in every district of South India. The cost would be but trifling compared with the vast revenue the land yields the State, and I am confident that eventually satisfactory results would be secured. For a time we must be content to sow, feeling assured that, if proper means are taken, a harvest of good results will certainly follow. Agriculturists are slow everywhere in adopting improvements. It is unfortunate that, in dealing with the great question of agricultural reform in India, narrow-minded, unintelligent views have been allowed to crush the germs of reform. The matter must be viewed from the same standpoint as ordinary educational efforts. If the expenditure of £100,000 a year on literary education in South India is justifiable, surely the expenditure of a few thousand pounds annually over that country, in promoting the material interest of the classes amongst whom we are so anxious to create M.A.'s and B.A.'s is, to say the least, equally justifiable. But, then our land administrators are "classical scholars," not agriculturists, and their panacea for the deplorable state of the agricultural classes—and, let it be remembered, India is essentially an agricultural country—is education in Greek and Latin.

When Sir William Denison became Governor of Madras, attention was again directed to agricultural improvement, and this was kept up until Lord Napier, who succeeded Sir William Denison ceased to be the Governor of the Presidency. A large number of agricultural implements and machines were then purchased in this country, but, when they arrived in India, it was found that they could not be worked under suitable conditions, Government then having no suitable land under its direct control on which the machines could be worked. The necessity for testing these machines, &c, under proper superintendence suggested to the authorities in 1865, the propriety of establishing a Government farm; and a piece of land of about 300 acres, situated about six miles to the south of Madras, which was then covered by a prickly-pear jungle, was selected as the site of the farm. The selection was made because the land was the property of Government, and because the medical authorities had declared that it was absolutely necessary to clear the land, as in its then state it was the cause of much fever in the neighbouring town of Saidapet. A committee of Government officials was appointed to manage the farm. At first, operations were confined to clearing a few acres of land, sufficient to afford opportunities for trying field implements, chiefly light ploughs. For some years after opening the farm, but little was done beyond clearing the prickly-pear jungle, laying out the land in fields, making roads, and erecting cattle-sheds. The committee got together some useful varieties of farm stock, and conducted several small experiments in growing new crops. But their attention was chiefly confined to implements of which they imported several useful kinds. At this period of the farm's existence, the chief aim of its conductors was simply to show that European implements of a suitable kind, could be worked with success by the cattle of the country. They also gave attention to water-lifts, of which they purchased and erected several of different kinds for experimental trials.

In 1871, this committee was abolished, and the general control of the farm was given over to the Presidency Board of Revenue. It was then proposed that the farm at Saidapet should be a central experimental station, with branch experimental stations in each district of the presidency, the whole to be conducted by a small department, then organised with head-quarters at Saidapet. The objects to be kept in view by the department were specified by Government to be as follows :—

(1.) To ascertain, by experiment, the proper use of rotation in crops in this country.

(2.) To introduce the system of root or green crops, in lieu of fallow without artificial irrigation.

(3.) To introduce new crops.

(4.) To provide new kinds of seed; and fresh seed for the crops now cultivated.

(5.) To make experiments in the use of water for the cultivation of crops now termed "dry" crops, and for raising grasses and other crops to be used as fodder.

(6.) To make experiments in the use of lime and other manures, mineral and animal.

(7.) To introduce new and improved implements of rural labour.

(8.) To improve the working cattle, sheep, horses, and other varieties of live stock in the country.

These objects have been steadily kept in view in the management of the department, as far as its very limited means permitted, or as the controlling authorities would allow.

The first difficulty that presented itself in attempting to carry out the scheme was, the absence of qualified natives, who alone were to be placed in charge of the district stations. To meet this difficulty, Government authorised the entertainment, at Saidapet, of a number of youths who were to be trained there, for employment afterwards as superintendents of these stations. These youths were to become qualified for their difficult duties merely by taking part in the ordinary operations of the farm. Though liberal stipends were offered, and promises were held out of future employment on liberal salaries, no well educated youths, of the stamp required, could be induced to join this apprentice class.

The fact was, as agriculture was at that time known to the people generally, it was estimated a pursuit only fitted for the unintelligent portion of the community. A class was formed of the sons of subordinate officials and others, who duly appreciated the high stipends (Rs 40 per month) offered, but it was soon ascertained that mere field-training would never fit men of the sort forming the class to hold the responsible position of superintendents of experimental stations. After a very full trial, the fact was recognised—a fact well known before to those acquainted with the subject—that in order to provide qualified native superintendents for the district experimental stations, it was absolutely necessary to secure well educated youths, and to subject them to a prolonged training of a systematic kind. In this view, the Revenue Board of that day fully concurred, as the following extract from one of their published proceedings shows:—

"(1.) That unless systematic instruction in agriculture and the sciences bearing on it is given at the Saidapet farm, competent superintendents for the experimental farms, which are to be instituted, cannot be trained there.

"(2.) That without superintendents trained in this way, the experimental farms will be of little or no use.

"(3.) That the means for giving such a training, the lecturers, the students, and the opportunities for practising what is taught, and the funds, are all available.

"(4.) That the good effects of the instruction will not be limited to a few superintendents of Government farms, but will slowly leaven the agriculture of the whole country, as in England, America, France, and Germany.

"(5.) That as a scene of systematic instruction open to all comers, the Saidapet farm will be infinitely more useful to the public than it is at present."

It was only after a great expenditure of time and effort in discussing the question, that a reluctant consent was obtained for the establishment of an agricultural college, on a small scale, at Saidapet in which youths could be trained for employment, as superintendents of district experimental stations, and agricultural instructors; for private employment, &c. A comprehensive scheme was organised, and its details extensively published in the form of a prospectus. Though the institution was originated in view to train district farm superintendents, &c., no inducements of any kinds were held out of State employment for those who passed successfully through the institution. Indeed, there was a nervous anxiety at the time that every candidate should clearly understand that, in qualifying as an agriculturist in the institution, he would thereby establish no claim whatever on Government. In connection with the institution, 24 bursaries were established, each worth about £15 a year and tenable during 2½ years of the three years of training. Those bursaries could only be got and retained by really industrious students after six months' attendance at the college, and who continued during their whole course of training to keep up to the standard of progress laid down. A high minimum of marks was to be gained at each of the twenty or more examinations of each session, while evidence of a thorough practical acquaintance with the working of ploughs and other field implements was insisted on.

After a sufficient time had elapsed to allow of the thorough publication of the prospectus, and for a full discussion in the native press of the objects and nature of the new institution, applications from would-be candidates began to be received in considerable numbers, and from nearly all parts of India. No candidate was accepted who had not qualified in the educational standard prescribed for ordinary State employment, or for proceeding to a University degree, or who failed to pass the special (equally difficult) entrance examination of the college. All candidates had to produce medical certificates of physical fitness for active employment, certificates of character, &c., and each candidate selected was between the ages of 18 and 24.

Notwithstanding the previous repeated failures in filling the apprentice, classes, when such substantial advantages were offered, there was no difficulty now in securing any number of qualified, educated youths. The institution began work in 1876, with a first class, in temporary sheds. The erection of commodious but unpretentious buildings was sanctioned, in which to carry on the work of the institution. The permanent accommodation was to consist of lecture-rooms, class-rooms, a reading-room, and a library; and separate buildings were to provide accommodation for a veterinary hospital and a chemical laboratory; while, in addition to the farm, botanical grounds were to be established; but only the chemical laboratory has yet been erected. The nature of the training afforded by the institution, will be gathered from the following extracts from the college prospectus:—

"The instruction given in the institution will embrace a thorough study of agriculture, and of such portions of chemistry, geology, zoology botany, and the veterinary art as bear on the theory and practice of agriculture. In addition to these special subjects, the following will also receive attention:—Farm book-keeping, land surveying, mensuration, and drawing. The instruction will be given by means of lectures, class-room discussions, and field classes.

"During the portion of the day set apart for practical instruction in farming out of doors, every student will be expected to take part in whatever work is going forward on the farm; compliance with this regulation will be strictly enforced. Each student will be expected to make himself acquainted with all the operations daily performed on the farm, and will be required to keep a journal or diary of the same."

In 1878, a second class was formed, and applications for admission into it were even more numerous than they were for admission into the first class. That there was a widespread demand for agricultural instruction was amply evident.

In reviewing the work of the institution at this period, after it had been at work for nearly three years, the Government of the Presidency, in a published order, stated, "the progress and working of the institution have, on the whole, been very satisfactory."

A change of policy, however, took place at about this time in the treatment of the institution, partly under the influence of the general State policy of reduction of expenditure, from which that department suffered. And of the twenty-four bursaries attached to the institution, nine were then suppressed, and these were afterwards reduced to five only in a class; while the value of the bursaries was reduced from about £12 to £8 per annum. The entire saving to the State by these reductions would amount to only about £100 a-year; but the effect, combined with other causes, was highly injurious to the institution, for, when it was again attempted to form a new class, only seven eligible candidates were secured.

The practice of paying stipends, or bursaries, to youths undergoing special training, is almost universal in India, in the Medical, Forest, Educational, and Engineering Departments. Very few students from the agricultural districts can afford the expense of journeys, frequently long and the cost of maintenance away from their homes, during a three years' college course. The provision of bursaries to aid indigent able students, is as necessary, to say the least, in South India, as in Scotland, Ireland, or England. A time may, it is hoped, arrive when agricultural education in India may not require to be aided in this way; but as long as such aid is necessary in every civilised country, it surely was permature to withdraw such aid from the but recently started agricultural institution in Madras.

Only one class of students has completed the full period of training in the Madras College. Of these young men, the majority are filling agricultural situations, and generally with credit; eight of them are employed as agricultural instructors in the Bombay Presidency; but, in Madras, none of the graduates of the college have yet been employed by Government, though there were several well fitted, after undergoing a little special training for the posts of agricultural instructors, and for superintendents of experimental stations, the establishment of which has been deferred so long from the impracticability of previously getting qualified native superintendents.

In Madras, the Educational Department is now beginning to give attention to agricultural instruction, the subject being now taught in several of the rural schools, but nothing of a comprehensive nature can be done in this way, until qualified agricultural teachers are available. And men can become so qualified only by undergoing training in the Madras Agricultural College, which, at present, is the only institution of the kind in the whole of India, and which, I venture to believe, is as fully deserving of State support as any other technical institution in the country.

I never could understand the nervous fear that appears to exist in some quarters, lest students of the college should look to State employment as affording a career in after life. The State employs, in the administration of its vast landed estate, thousands of officials of all grades who are totally without any agricultural education. Many of these officials are employed solely in valuing the land for rent, in collecting agricultural statistics, and in many other ways connected with agriculture. Surely there can be nothing wrong in any agricultural student looking forward to employment in any of these capacities, provided he possesses, in addition to his agricultural knowledge, the qualifications all must possess who seek for such employment. I should have thought that, for the performance of agricultural duties, preference would be given to men who possess a knowledge of agriculture; but so far graduates of the Agricultural College have encountered nothing but difficulties in seeking for State employment where a knowledge of agriculture seems essential. From what I can gather, it appears that the obstacles are put in their way chiefly by the officials of the inferior classes, who do not like the idea of better educated men than themselves getting admission into their ranks.

The Agricultural College has been organised; the central institution for agricultural training in the Presidency of Madras, and it was intended only to afford higher agricultural education. It was proposed that elementary instruction in agriculture should be afforded in the high school of each district with which the branch experimental stations were to be connected, but, as yet, none of these agricultural classes or stations have been established. The college suffers from the absence of these classes, which were intended to be its main feeders; while the course of training in it has been prolonged, from the necessity of the institution undertaking elementary as well as more advanced instruction.

Youths of the ordinary ryot class, the sons of small occupiers, will, in the agricultural classes, at the high schools and middle class schools in the districts, meet with such facilities for gaining a knowledge of the principles of agriculture as appear suited to their requirements. The sons of ryots of the better class, and of small zemindars, with others who

desire a more complete agricultural education, will, it is proposed, pass from the local agricultural instruction classes to the college at Saidapet.

I have dwelt at considerable length, and in much detail, on the subject of establishing the Agricultural College at Madras, because I am anxious that the facts should be thoroughly known and appreciated. The experiment is one of the utmost importance in India, and it should receive fair treatment. Should any erroneous conclusions be formed regarding it, agricultural education, so much needed in that country, may be retarded for years. There are always a number of persons ready to cry out failure when anything new is being tried, and already there are persons glorying in the fact, as they assume it to be, that the college has not been a success, as if it was yet possible to form any definite conclusions on an experiment of such a nature, and conducted under so many difficulties. These persons assert that the bursaries drew the students, and that when the bursaries were done away with, the attraction ceased. Such persons, however altogether (wilfully or unknowingly) misstate the facts. The bursaries were, undoubtedly, of much benefit to the student in enabling them to meet the heavy cost of not unfrequently long journeys to and from between the college and their homes at the beginning and end of each session, and, indeed, also in meeting the personal expenses of the students at Saidapet. But many of the students must have spent a great deal more on travelling charges and text-books alone than the entire amount they received in bursaries, or scholarships. The aid thus originally given was only such as was barely necessary. It could in no sense be looked upon as an attraction sufficient to bring sudents hundreds of miles from their homes. The majority of them came from places more than 200 miles from the college, several from remote parts of the Bombay Presidency, to undergo hard training of previously unknown kind for three years at the Agricultural College, more especially as there was no prospect held out as there is in the technical institutions of the Forest, Educational, Medical, and Engineering Departments of India, of State employment for successful student.

The Famine Commission have proposed a very extensive scheme of agricultural instruction for Indian civilians at the expense of the State. The cost that would be incurred, for affording each such civilian a knowledge of the principles of agriculture, would provide bursaries sufficient for the entire requirements of the Madras Agricultural College, and secure to it a regular attendance of at least 100 qualified students, while not adding to its working charges; for, I need hardly remark, that a course of lectures for a class of seven or eight students is quite as costly as for a class of thirty or upwards. The benefit that would result to India from the general diffusion of agricultural knowledge amongst the rural classes cannot be overvalued. If, as the Famine Commission report asserts, great benefit would result to India if the European Land Revenue officers possessed a knowledge of the principles of agriculture, it surely is equally true, and, to a far greater extent, that a similar knowledge amongst the thousands of native officials scattered over the country, in close daily intimacy with the agricultural classes, would be productive of far more good in the promotion of agricultural improvement.

Ordinary education, which is gradually spreading its beneficial influences over the country, will, in time, create inquiry, even in the mind of the ryot, and efforts to improve the present state of matters will, no doubt, be made; but the general reform so urgently needed in the husbandry of the country, would not, in this way, be secured in the next 100 years, and the demand for reform is of far too urgent a nature to wait for even a single year's delay. Seeing that the State in South India, though administered by Englishmen, grudgingly spends the one-ninth per cent. of of its rent roll, for promoting agricultural improvement throughout the presidency, there is nothing surprising in the fact that native landowners should be so apathetic regarding the condition of their properties, and the well-being of their tenantry. Before any decided comprehensive improvement can be made in native husbandry, agricultural education must be placed within the reach of every class of agriculturist. The fact that the land pays four-fifths of the gross revenue of the presidency, and that two-thirds of the population are employed in the cultivation of the land, should never be lost sight of in considering questions relating to the improvement of Madras agriculture.

I have already referred to the establishment of the Central Experimental Farm at Saidapet. The following extract from a report submitted by me to Government, shows the nature of the work in which the farm is engaged :—

"The farm being the only one of the kind in South India, it has, necessarily, been obliged to undertake much work in experimental agriculture, of a kind not usually undertaken by experimental farms in other countries. From the almost entire absence in any writings on the agriculture of the country, the ignorance of the people generally, who are engaged in agricultural pursuits, and the imperfect character of the records of the results of previous efforts in improving native agriculture, there was no choice but to institute on the farm experiments of a very elementary character. It will readily be understood that experience gained in this way accumulates but very slowly, as each result needs to be confirmed under different conditions and circumstances before any decided conclusions are possible. The institution has had to do the work of an acclimatis and agricultural society. It has been engaged in introducing and modyfying machines, implements, and tools of other countries adapted to the requirements of Madras agriculture. Attention has been given to subsoil drainage, improved methods of tillage, the restoration of exhausted soils, the utilisation of irrigation water, the fertilisation of arable soils by the use of lime, saltpetre, oil-cake, poudrette, and other manures available in South India, but hitherto unused by the ryot; the introduction of the new crops suited to the climate of India and adapted for cultivation under an improving agricultural practice, such as maize, *Sorghum saccharatum*, Carolina paddy, Guinea grass, and other grasses; New Orleans and other improved varieties, of cotton; tobacco of all kinds, the production of live fences in view to affording protection, shelter, and fuel; the introduction of water-lifts, barn-machines, ploughs, cultivators, reaping knives, &c., of improved construction suited after undergoing modificaton for use in South India, the improvement of native live-stock by careful breeding and feeding, and by importing and acclimatising animals of good breeds for inter-breeding with native stock."

The following analysis, made shortly after the farm was established, will give some idea of the poverty of its soils at the time; the soils analysed were some of the best on the farm :—

Constituents.	No. 4. Field	(eastside).	No. 1 Field.
	Surface soil.	Sub-soil.	Surface soil
	Per cent.	Per cent.	Per cent.
Alumina	4·420	2·060	8·240
Oxide of iron	1·800	2·900	1·850
Phosphate of lime	·240	·009	·120
Carbonate of lime	·700	·560	·310
" magnesia ...	trace.	trace	trace
Sulphate of lime	do.	do.	do.
Chlorides	1·080	·720	·900
Moisture	2·760	1·420	2·090
Organic matter	2·500	1·710	2·120
Sand	85·900	90·400	89·870
Total	99·400	99·800	100·900

The farm, being without natural pasturage of any value, it became necessary, soon after it was opened, to undertake experiments in producing fodder for the valuable stock it possessed, Attention was first given to the crops which, in Europe, furnish green fodder; but it was soon ascertained that, with the exception of lucerne, they were ill-adapted for culture in the hot plains of South India. Most of the plants grow fairly well in the cold season, but died off immediately the hot weather set in. Amongst these crops were *Lolium perenne, Lolium Italicum, Trifolium incarnatum*, lucerne, vetches, millet, and a great variety of pasture grasses. Seeds of grasses and fodder crops were also obtained from the United States, Mexico, New South Wales, Queensland, China, *Egypt, Italy, &c.* The prairie grass and buffalo grass of the United States, were quite unable to stand the great heat of Madras. Several varieties of native grasses from Queensland have thriven as well as could be desired, but they are far inferior to European grasses.

Guinea grass (*Panicum jumentorum*) has been thoroughly established and now affords the chief pasturage at the farm. The cultivation of Guinea grass has been wisely extended. The grass is much coarser than any European pasture grass. All kinds of stock eat it freely, and thrive on it. When it was first introduced at the farm, it was grown as an irrigated crop. But it was thought, that if the habits of the plant could be altered, it might become adapted for cultivation on unirrigated land. Accordingly, several experiments were commenced with this view, the results of which have proved highly satisfactory. At the farm, at the present time, there are considerable areas of this crop, which, for at least three or four years, have depended entirely on the rainfall. This result has been obtained chiefly by inducing the plant to send its root deeper into the soil, and by gradually accustoming it to smaller and smaller applications of irrigation, water applied at gradually lengthening intervals, until finally discontinued. *Sorghum saccharatum* and *Sorghum caffrorum*, imported from China.

United States and Australia have, through the farm, become thoroughly naturalised in Madras. When these valuable crops are more generally cultivated, there is every probability that the manufacture of Sorghum sugar will be largely engaged in. The experiments made at the farm show that both plants contain a large amount of sugar, that the saccharine juice is very easily extracted, and that the waste, after crushing affords a very valuable cattle food. The Agricultural Department of Madras is using its best endeavours to extend the cultivation of these crops chiefly in view to the provision of fodder for use in the hot dry season, when the natural pasturage is all burnt up. Crops of from 15,000lbs. to 20,000lbs. per acre of most excellent fodder have been raised on the poor soils of the farm, without the aid of irrigation, during growing periods, varying in length from eighty to one hundred and five days. But by far the best results in growing fodder were obtained with the previously despised indigenous cereal crops of the country. Amongst these I may mention *Sorghum vulgare, Penicillaria spicata, Panicum Miliaceum, Panicum miliare, Panicum Italicum, Eleusine coracana*. and of the leguminous order, *Dolichos uniflorus*. Several of these crops, under very ordinary tillage, and without irrigation, have yielded crops of fodder of over 20,000lbs. per acre, in periods of from seventy to one hundred days. With occasional irrigation *Sorghum vulgare* has, within twelve months, in several cuttings, yielded crops of fodder

weighing upwards of 50,000lbs. per acre, and in one experiment as much as 80,000lbs. per acre was obtained, and standing generally over the ground about twelve feet high. The cost of producing fodder from these native plants is seldom higher than five shillings per ton, a price very considerably below its feeding value. The fodder is usually rich in saccharine matters, and very succulent and digestible.

Many experiments have been made with native grasses; the majority of them have been found to be very coarse, and almost worthless except ing when very young. There is one grass, however, *Cynodon dactylon*, which gave very good results under high manuring and occasional irrigation. Further experiments are being made with native grasses, and with the grasses of other countries likely to thrive in South India. The discovery and extended cultivation of some really good grasses in South India would prove of immense advantage to the country.

Maize, introduced from America, Egypt, and North Australia, has thriven at the farm, and a large amount of seed has been distributed over South India.

Wheat of Northern India has been tried, but its cultivation has not yet proved a success, chiefly due to the great heat encountered at Madras. In some portions of the presidency, at elevations of from 20,000 feet and upwards, wheat of fair quality may be produced, but generally, the variety grown is inferior sp... .c./.

Of fibre crops, many varieties have been introduced and cultivated at the farm. Of these, I may mention *Cannabis sativa*, *Corchorus capsularis*, *Crotalaria juncea*, *Linum usitatissimum*, *Boehmeria nivea*, and cotton of various kinds.

When the farm was instituted, it was believed generally that cotton could not be grown successfully on such light soils as those constituting the farm. However, it has been shown most conclusively there, that abundant crops of very fair cotton can be produced at a profit; while over the presidency generally, on soils far superior to those of the farm, the yield of clean lint is only, on the average, about 60 lbs. per acre; the average outcome per acre on the farm is fully three times this weight, while the price obtained is as high as for any cotton produced in South India. The farm has grown extensively Egyptian, New Orleans, Upland, Sea Island, Yea Valley, and other varieties, the seed of which has been distributed to native cultivators and others. Many other kinds of crops have been experimented with; crops obtained from tropical countries abroad; crops introduced from the other provinces of India; and crops of South India not generally cultivated, or badly cultivated, apparently deserving of attention. But I cannot occupy your time in referring more fully to these crops. Those who are interested in the matter, and who wish for further information, will find full details in the annual reports of the Madras Agricultural Department, and in the "Saidapet Farm Manual, the latter a compilation from these reports. During the last ten years, many field experiments have been conducted at the farm with manures available in South India, but which, until recently, were almost unused in native husbandry. The results obtained with these manures have been widely published in the reports of the department, and by other means. The experiments have shown that there is a great amount of valuable manure now wasted which the ryot could with great advantage, apply to his starved soil. Seeing that South Indian agriculture is so dependent on irrigation water, the proper utilisation of this water has occupied a good deal of attention on the farm. It has been shown there that good crops of paddy can been produced, even on sandy soils, with an expenditure of water less than one-half the quantity generally used in native husbandry; results obtained chiefly by deeper tillage and the use of organic manures. Experiments extended to unirrigated land have shown that, with deep tillage and the moderate use of vegetable manures, these soils are enabled to take up large quantities of moisture from the air during night, and to retain and store it; thus practically securing irrigation from the air. In this direction a great deal could be done in developing the drought resisting powers of a large area of land in South India, a result the import nce of which I need not occupy time in pointing out.

The heavy expense incurred by the ryot with his primitive arrangement for raising water from wells, early attracted the attention of the managing authorities of the farm, and many experiments were instituted with pumps and water-lifts of different kinds, driven by steam-power, wind-power, by cattle, and by manual labour. Several of the water-lifts, of the patterns most highly approved, for a long time, been regularly worked on the farm, thus affording native cultivators interested in the matter every opportunity of judging for themselves the working capabilities of these machines. One of these water-lifts, which can be made up by almost any village carpenter, raises the water at less than half the cost at which it is raised by the primitive arrangement generally used in South India. This improved water-lift has been constructed in many places from drawings, or models supplied from the farm.

In my first paper (7th May 1880) I referred very fully to the advantages the European pattern plough possessed over the ploughs employed by native cultivators. The Saidapet farm has now, for 12 years, been worked entirely by ploughs of the modern make. They are each drawn by a moderate sized pair of cattle, and driven by a single native ploughman. Ploughs have been imported from England, Sweden, and the United States. The light pony ploughs, made by Messrs. Howard & Co., of Bedford, and Messrs. Ransomes, Sims, and Head, of Ipswich, have proved great successes. Some of the ploughs now working on the Saidapet farm, and that have been regularly worked there for the past 12 years, are still in a thorough working order; of course, they have been kept in thorough repair.

The results of the experiments made at Saidapet have shown conclusively that it is a great mistake to recommend ryots to buy low-priced ploughs simply because they are low-priced. It is a far greater economy to pay £2 or £3 for a really well-made iron plough, than to pay 10s. or 15s. for a rudely constructed plough, made of wood with iron working-parts, which is constantly needing repairs—often when work is pressing—and seldom lasts longer than two or three years. There are certainly many ryots who do not possess the means where with to buy a plough of the kind I recommend, but there are tens of thousands who do. It would be as ridiculous to state that steam-ploughs cannot be used in England, because each farmer has not the means to supply himself with such an apparatus, as to state that in India good ploughs of the modern shape cannot be introduced, because the ryots are too poor to buy these ploughs.

The improvement of live stock has occupied much attention. There are no facilities at Saidapet for maintaining a large breeding herd of cattle, but a number of bulls are kept there for improving the stock of the neighbourhood. A breed of cattle imported from Aden, has been introduced with success. The breed is noted as a dairy breed. It is hoped that, by the use of bulls of this breed, the milk producing capabilities of the cows of the indigenous breeds may be considerably improved. When I mention that the average yield of milk of an ordinary native cow is less than two quarts per day, you will understand what room there is for improvement, an improvement which would be a benefit to the people generally, for nearly all would be consumers of milk, if they could obtain it at a moderate price. Experiments made on the farm show that an average cow of Aden breed will yield daily at least six quarts of good milk. Experiments have also been made in determining the milking capabilities, under good management, of different native breeds, and of crosses with European breeds. The housing and general management of horned stock have also received attention. How necessary this is, you will understand when I tell you that the cold rains which accompanied the cyclone that broke over the neighbourhood of Saidapet in 1877, destroyed, in the Revenue Division in which it is situated, 11,687 cattle, and 7,218 sheep, in a live stock numbering 80,000 head of cattle, and 16,000 sheep. On the farm, which was exposed to the full force of the cyclone, the loss was only three sheep. Shelter in India is almost as necessary for live stock as it is in England.

I should have liked to have described to you more fully the actual work of the Madras Agricultural Department, but I have already trespassed so far on your time and attention I must forbear. The reports before alluded to describe fully this work and such indications of progress in agricultural reform as have been ascertained. Looking back over a period of twelve years engaged in this uphill enterprise, though I cannot point out any great or bright examples of progress, I feel satisfied that much good has been done chiefly in collecting facts and spreading information which, when the time comes for energetic work in agricultural reform, will bear fruit. Already, as I have pointed out, agricultural education, which would have been an impossible undertaking only a few years ago, is now beginning to beneficial influences in the country, influences which I firmly believe, will do for Indian agriculture what could be attained by no other means.—*Society of Arts Journal.*

AMERICAN VIEWS ON NITROGEN IN PLANTS.

THERE has lately been so much discussion in this country as to the sources from which plants derive the nitrogenous elements necessary for their healthy and proper development, that the following paper on the subject delivered before the Pennsylvania Board of Agriculture by Professor Reidenbach, may be read with interest:—

I. Almost all if not all, the nitrogen contents of all vegetation is derived by the plant from or through the soil. It has been maintained by some that certain orders of plants particularly from among agricultural vegetation, the broad-leaved root crops, derive at least a small portion of their nitrogen through their leaves from the atmospheric nitrogen or nitrogenous compounds. This to say the least, is extremely doubtful.

II. Nitrogen exists in the soil in three classes of condition:—

(a.) Those compounds which are insoluble, and are the intermediate products of vegetable decay—classed as nitrogenous organic bodies, &c.

(b.) The soluble compounds of nitrogen, including ammoniacal and nitrate salts.

(c.) Free nitrogen held in solution in soil water are in the air, held in the pores or condensed on the surfaces of the pores of the soil.

III. The nitrogen of the soil is derived from the four sources:—

(a.) From the decay of former vegetation as stored in the soil.

(b.) From the air carried down as ammonia, nitrates, and organic dust in solution, or suspension in falling rain, snow, and dew.

(c.) From the circulation of air through the pores of the soil.

(d.) From additions in the form of barnyard manure or chemical artificial fertilizers.

IV. Nitrogen in the insoluble form, and as free nitrogen, cannot be assimilated by the plant. Hence the two food forms of nitrogen are ammoniacal and nitrate salts, and in the light of our informa... on the subject

seems very probable that it is in the latter fo. n or er nitrates, that the plant finds the cond t.ons in which it is best able to avail itself of nitrogen as food offered to it. Here r many other cases where we attempt to question the proce es of nature we find ourselves unable to obtain a definite answer to our query. In this instan the e are on record certain admirable experiments, some quite rec t, which seems to indicate that in some cases, with certain plants under cert n conditions of age and treatment, the plant is be able to avail itself of the nitrogen offered in the form of ammonia. But the general s' tement, given above, is expressive of the mo t successful practice and experiment.

V. The soil has, to a certain exten t, the power of retaining v th'n itself the soluble nitrogen compounds (ammonia and nitrates) by partly physical, but more by chemical absorption.

VI. But, in consequence of their solubility these same assimilable forms of nitrogen are al o likely to be lo t by the action of the percolating waters. A discus on of th e principles would be interesting; but we pass this by to the consideration of several inquiries which these principle render of extreme pr impotance.

(a.) What is the re on of at nosphe.ic nitrogen to the fo l supply through the soil.

(b.) What conditions are favourable for rende.ing the nitrogen of the soil stored or added, nilable ?

(c.) What conditions are favourable to the retention of assimilable nitrogen in the soil and bringing it to those layers of the soil through which the main portion o e roots ramify.

(d.) What rela o do different kinds of crops b ar to the food supply of nitrogen ?

(e.) If nitrogen is to be add s a fe il er, in what form is it most conveniently and ch ply applied ?

In other words we inquire, "How can we bring the nitrogen of the soil into condition favourable to plant g ow h ? How prevent its undue loss. How arrange our crops to most economica y utilize the nitrogen into soil ? And how can we add nitrogen to the best advantage ?" I must repeat here that I can only give but a brief outline of the answer to each topic.

(a.) What is the rela on of atmosphe c nitrogen to the food supply through the soil ?

You are aware that about four-fi s (79·100) of the atmosphere by volume and slightly l s by weight (77.100) is free nitrogen, which is inert, and as free nitrogen is not available f plant nutrition. In addition to the free nitroge the atmo-phere als contains traces of nitrogen in the form of an monia and nitrat , formed by action of decay, and carried into the air d also by other process. Ammonia is rarely in excess over e nitrates. These compounds being soluble in water are c ied down by rain and dew into the soil. Caref determinations show that the amount thus obtained from the measured fall—that is, from rain and snow r one—is from eight to ten pounds per acre, on the average for each year. The amount carried down by dew has not been ascertained, but it is probably an important amount. Indeed, it may often be very considerable. To this we must add the atmospheric source of nitrogen, free of compound, fixed and retain l by the soil by some chemical action with which we are not acquainted, brought into the soil by circulation of the atmosphere through its pore . Experim its made at Rothamsted, England, by Gilbe. and Lawe indic s this as a very important source of nitrogen for plant fo l. We thus see t t the atmosphere not only supplies all the carbon of the plant, and the water nec y, but also is a reservoir of nitrogen, from which there is a cer n, though variable, supply given to the soil. How far this supply of n..ogen is sufficient is an important and as yet unanswered inquiry.

(b.) What conditions are favourable for rendering the nitrogen of the soil, stored or added, assimilable ?

We have already referred to the nitrogen in the soil in two classes of conditions, available and not available for the plant. It is of value to the farmer to know if he can assist Nature in bringing the unavailable nitrogen into an assim lable or available form. I briefly mention some of the leading conditions for bringing about this change. The presence of mineral fertilizers, particularly of potash and carbonate and sulphate of calcium—that is, limestone and gypsum. The presence of oxygen of the air and such substance as can supply oxygen, among which red o de of iron, as found in our Adams coun.y red sha'e, sulphate as gypsum. Moisture acts as an agent or change. A free circulation of the air also promotes the s.me change. Among other reasons why these conditions are favourable to our purpose, they tend to promote the conversion of other nitrogen compounds into nitrates, the proc ess known as nitrification. The mineral fertiliser phosphates and potash salts facilitate to a wonder- degree, partic .ly on clover and other leguminous plants, the bringing of the t trogen of the air into a condition of ava..abilit. On the other hand, the presence of caustic lime causes a serious loss of available nitroge in converting even the already formed nitrates into ammonia and preventing their form and, ammonia thus formed passing into the air. It is hardly necessary to s that he physical condition of the soil has much to do w. this c, ae nitrification—such treatment as promotes moistu e during dry, hot weather, and renders the soil ...ble, ate impo. nt adjunct; also the pres ce of sand and marl. I ... add a condition which we ro not a. e to ...co, but we .n modify its action. I refer to the fact that ... is more ... during

hot weather; but if the soil is very dry at the same time, or so compact as to exclude oxygen, ammonia may be formed from nitrates themselves, and thus be lost to the immediate use of the plant. You thus observe that during winter the nitrogen may remain as ammonia stored for the use of wet station during its active state. I have not spoken of ozone, or of ferments, or of rootlets, or of other causes of nitrification; because, though import nt, they are not under the active control of the former."

(c.) What conditions are favourable for the retention of assimilable nitrogen in the soil ?

The mention of the causes of loss will suggest the remedies. The principal loss is found in the solubility of nitrates and ammonia in water. In soils with near lyi ng impervious subsoil, the drainage may cause a very considerable carry ing away of these other nutritive elements, as is shown by analyses of spring, well, and river waters. Another loss is found in the formation of ammonia, and yet another is caused by the absence of those m inerals compounds which act as absorbents, chemical and physical, of nitrog en compounds such as phosphates carbonate of lime, and gyp sum. One remedy against loss is to have a soil in that condition of looseness by ploughing and hoeing as increases the absorbing power for water, and decreases the evaporating power.

(d.) What relation do different kinds of crops bear to the food supply of nitrogen ?

We consider this question first in the amount of nitrogen found in different crops. If we have a a average crop of twenty-eight bushels of wheat, with twenty-five hun d pounds of straw, about forty-five to forty-eight pounds of nitrogen will be found present. In a crop of two and one-half tons of meadow hay, fifty to sixty pounds (that is, to each ton, twenty to twenty-f ur p s), a d in a crop of two and one-half tons of clover, from one hundred to one hundred and fifte n pounds of nitrogen (each ton conta ing forty to forty-six pounds). In general the legum nous rc, c ver, beans, vetches— e rich in nitrogen, while the cereals and gra ses are relatively poor in nitrogen. Now comes the remarkable fr , shown by many investigations, but recently and remarkably demons.rated f o: thirty years' culture on trial plots of various crops by Gilbert and Lawes, that the poor in nitrogen crops—namely, cereals and gr sses—require the presence of a larger quantity of assimilable nitrogen than do those rich in nitrogen. The experiments are grou ped in three classes, made in each case on both kinds of crop. —

(a.) With nitrogenous manure.

(b.) Without any manu .

(c) With mineral manure containing phosphates and potash, but not nitrogen.

The results may be tabulated thus :—

1. Without any manure, the nitrogen all crops gradually diminished and also the soil cont t was lessened ; that is, the crop diminished.

2. With mineral manures, the amo unt of nitrogen in the cereals still diminished, as also in the soil, but at a somewhat less rate ; while the nitrogen of clover and beans is diminished but little, and the *soil content, even increased.* In other words, the mineral fertilizer particularly potash, enabl the clover to use more nitroge n, and thus to produce a good crop, and at the same time increase the store of nitrogen in the soil, even rend e ring it assimilible.

3. What is more remar kable, the crops rich in nitrogen derive far less benefit from nitrogenous manures than do those poor in nitrogen.

4. Root crops exhaust particularly the superficial layers of soil of their nitrogen, under any of these conditions.

W e have no time to-day to i quire into the reasons of these facts, but they are of most practic l importance.

Two conclusions must appear :—

(a.) The leguminaceæ must draw a considerable portion of their supply of nitrogen from the air, and, as already stated, through the soil.

(b) Mineral fertilizers have at least as valuable indirect actions in reference to supply of nitrogen, as direct in furnishing potash and phosphorous to the growing plant.

(e) If nitrogen is to be added to the soil in fertilizers, in what form is it most conveniently and cheaply applied ?

Our answer has already been suggested. Clover is the best, from the amount of nitrogen it gathers its own tissues, and from the increase it effects on the soil, besides the considerable amount found in its roots. Of mineral manures, nitrates are the best, particularly in dry weather. Sulphate of ammonia, in a wet season, is equally good. For leguminous plants, particularly for clover, no large quantity of nitrogen is required by ordinary good soil, but use a complex mineral fertilizer, containing a good percentage of potash.

From these sta tements we must conclude that from the air through the soil the plant gathers a large portion of its supply of nitrogen, but that crops having an equal power in thus utilizing the supply of nitrogen from the air, such a rotation of crops can be employed as will keep the supply of nitr ogen in soil always sufficient for the plant use.

ON THE BARK OF BROUSSONETIA PAPYRIFERA AS A MATERIAL FOR PAPER-MAKING.

Memorandum by D. BRANDIS, *Inspector-General of Forests, on the bark of Broussonetia paprifera as a material for paper-making,—dated the 29th November* 1880.

IN a memorandum on the subject of the cultivation of bamboo for paper stock, dated 8th July 1875, I made the following remarks regarding the Paper Mulberry :—

In conclusion, it may not be out of place to draw attention to a tree which is grown largely in Japan as coppice wood on a short rotation similar to osier-beds, and which furnishes a large proportion of the paper stuff used in the country. This is the Paper Mulberry (*Broussonetia papyrifera* : 'Forest Flora of North-West India' page 410.) This tree appears to accommodate itself readily to different conditions of climate ; it thrives in Western Europe, on the South Sea Islands, and in Siam, and there seems every reason to believe that its cultivation may succeed in North-West India. I know of few trees more promising (in a suitable climate) for the supply of paper stuff on account of its free and rapid growth and the abundance of its fibre.

In the report on the progress and condition of the Royal Gardens at Kew during the year 1879, just received, the following passage regarding this subject occurs :—

Broussonetia papyrifera.—' The bark of the well-known Paper Mulberry supplies the material from which the tappa cloth of Polynesia and the bulk of the paper of Japan and China is manufactured. The Japanese cultivate the plant very much in the same way that we grow osiers, and they use only the young shoots for the manufacture of paper. A sample of the bark, which came into the hands of Mr. Routledge, is, stated by him to be ' nearly, if not quite, the best fibre I have seen.' * * * * * ' I must admit it is even superior to bamboo.' * * * ' It requires very little chemicals, and gives an excellent yield—62·5 per cent. in the grey, *i.e.*, merely boiled, and 58 per cent. bleached.'

The tree is indigenous in the Upper Salween forests of British Burmah, and as soon as reserves have been demarcated in that district, and officers placed in charge, efforts should be made to establish regular plantations. In March last I visited, on the banks of the Maytharouk River, a settlement of paper makers from Siam, engaged in making the well-known snow-white paper which is sold in the bazaars in Burmah. The procedure is of the simplest character, and the great advantage of this fibre is that it is white naturally, and that it is readily cleaned. It should also be cultivated as an experiment by forest officers at other places in Burmah, in forest gardens, or regular plantations.

And I would recommend that it be tried at the Sitapahar and Ramanpokri Plantations in Bengal, at Shillong, and at the Kulsi Plantation in Assam. It is not impossible that it will be found to succeed elsewhere in India, for the trees thrives in Western Europe where it stands frost and snow, in China and Japan, and on the South Sea Islands.—*Indian Forester.*

DARBY'S DIGGER.

DARBY'S Digger for several years has been familiar to frequenters of the principal agricultural shows as an imposing and somewhat complex apparatus. The determination, enthusiasm, and practical tact of the inventor has enabled him to overcome many difficulties and secure the satisfactory working of his machine. At the Royal Agricultural Society's Carlisle meeting in July 1880, deservedly received a special medal as "a new implement for the cultivation of the soil by steam or other mechanical force." Carlisle machine has satisfactorily dug 400 acres, and is still doing remunerative work. Now, however, a stronger and rather more effectual implement has been turned out, which has been carefully tested during several days lately at Writtle, three miles from Chelmsford, and will be again at work this week at the Bath and West of England show at Tunbridge-wells. The appearance and construction of the new machine are little changed. It consists of a locomotive boiler, with fire-box in the centre, tubes on each side, and a funnel at each end. The eight-horse power engine, fixed on the top of the boiler, has a single cylinder 9in. diameter. with 12in. stroke and 120lb. pressure. The engine is suitable for thrashing or other farm work. On the crank shaft are two pinions, one driving the four travelling wheels, which are 8½ft. high with tires 2ft. wide, the other driving the diggers, which are at the back of the apparatus, and consists of three sets of forks, each set containing 14 steel inch square tines with chisel points, which keep themselves well sharpened and are little liable to break. When the machine is to be moved through gateways, or has to propel itself along the road, the steering gear is removed and the wheels are turned half round, when the width is reduced to 8ft. The steerage apparatus, formerly at the rear, now runs in front, preventing compression of the finished work. The regulation or the depth can be simply and promptly managed without stopping. Spiral metal springs on the shaft regulate each set of forks and give them the requisite amount of play. An extra spring in front of the pinion carrying each set of forks would beneficially diminish jarring. Wrought iron has in many parts been substituted for steel, and in case of breakage is more easily replaced. The Governors on the engine would insure more steady work.

The digger has done good service for hire, the farmer at Writtle paying 20*s.* an acre for digging the rye-grass stubble just eaten off by sheep. On these terms Mr. Darby provides coal, of which one ton is consumed for the day's work of ten acres. The hirer draws water, of which about 200 gallons, or 18 cwt. are required every hour, which is drawn from the cart into the tank by an injector. A man and boy suffice to work the digger. The land at Writtle is a friable loam, dry and in a favourable state for cultivation. Neighbouring grain crops are looking particularly well, being more forward, and having suffered less from the drought and ungenial east winds than the cereals in most other parts of the country. Neither clovers nor meadow grass can now, however, prove full crops. Even the recent showers cannot provide the wanting bottom grass. The first grass crops cleared promptly away, the second may probably be more bulky. The digger takes fully 20ft. at each stretch ; the tines cut 10in. to 11in. breadth ; the depth can be regulated from 2in. to 12in. When we saw it about 6in. depth was being done, but the depth varied a little when going up or down hill. The three great forks, 6½ft. each, in rhythmical order as to the machine advances are raised about 15in. and thrown back about 2ft. In quick succession each fork inserts its 14 blades into the soil and deftly turns the furrow slice. The three forks acting one after another power is economized ; weight is also thrown off the wheels ; the thurst of the forks besides helps the apparatus forward. The best and most regular work was done when the machine was going, as it readily can do, at the rate of 100ft. in two and a quarter minutes. At a slower pace the slices were not as regularly cut or turned over. By a slight alteration of the mahinery the land can be turned entirely over as is often done in digging, placed on edge as in ploughing, broken down fine or left rough. An important feature of the work is the tearing out of twitch, thistles, docks, and other weeds, uncut, and thus more effectually insuring their destruction. Several Essex farmers who have had two seasons' experience of the digger, assure me that their land which has been dug has now fewer thistles than that worked by horses or steam plough. Proceeding across the ground already dug, the apparatus, although weighing 14 tons, is so well balanced on the four broad wheels that it does not seriously compress the loose soil, but turns it up in a very workmanlike manner. The calculated weight on the wheels per inch width of the tires is stated by the Royal Agricultural Society's engineer to be 816lb. Ponderous although the machine appears, it turns readily whether on the rye grass stubble or on the upturned ground in little more than half a minute. Its capabalities for cutting up hard well-firmed ground have recently been fairly tested by its successfully digging half a mile of a field road which had been in constant use for two years. In stony ground the tines are stated to stand better than the shares either of horse or steam ploughs. When the land is thoroughly wet the digger would probably drag heavily, but in such circumstances cultivation by any known agencies is undesirable. Making ascents, even reaching one in 25, skids are placed in the wheel, and effectively secure a firm grip.

The practical performances of the Digger now entitle it to take rank as one of the recognized implements of modern agriculture. It will doubtless, still undergo simplification and improvement ; it may even be reduced from its present price of £1,000 ; with its power economically applied in a very direct way it constitutes a cheap and effectual mode of successfully preparing the soil for most crops ; it appears capable of turning over ordinary loam soils 6in. deep at a cost of 7*s.* an acre, or several shillings less than it can be done by horses. It is likely to be more extensively used, not only in this country, but on the Continent of Europe and in the great treeless, stone less prairies of America.—*Times.*

ARTIFICIAL INDIGO.

A RECENT discourse was given at the Royal Institution by Professor Roscoe, F.R.S., on "Indigo and its artificial production." The Professor reminded the members of the institution that 11 years ago he had laid before them an account of a discovery in synthetic chemistry of high importance, that of the artificial production of alizarine—the colouring substance of madder. That was the first time the colouring substance of plant had been artificially obtained from mineral product. He had now, he said, to give an account of a second striking case of synthetic chemistry in a similar direction—the artificial production of indigo. It was another proof of the fact that the study of the most intricate problems of organic chemistry and those which appear to many to be furthest removed from any pratical application are in reality capable of yielding results having an absolute value measured by hundred of thousands of pounds. The value of indigo imported into this country during 1879 amounted to close on two millions sterling, so that if artificial indigo can be produced at a price to compete with natural indigo, there is a wide field open to its manufacture. Indigo has been known as a colouring matter from very early times. Cloth dyed with indigo has been found in the Egyptian tombs. Pliny and Dioscorides describe the method of dyeing which is the same as that followed in Bengal at the present day. The early inhabitants of this island obtained it from the European indigo plant *Isatis tinctoria*, the woad plant or pastel. After the discovery of the passage to India by the Cape of Good Hope, the Eastern indigo, derived from a species of indigofera, gradually displaced woad as containing more colouring matter. This however, was not done without strong opposition from the European Powers and their Sovereigns, some of whom issued edicts prohibitory to its importation. The identity of the colouring matter of woad and of the Bengal plant was not established till the end of the last century. Concerning the origin of indigo in leaves, various conflicting opinions have been held. Schunck has, however proved beyond all doubt that neither in the woad plant, the Indian nor the Chinese and Japanese indigo plant does indigo blue exist as such. The leaves contain a colourless principle. Which has been named indican

but this readily decomposes into (1) a sugar like body and (2), indigo blue. It was shown by experiment that even bruising a leave will produce this decomposition; but to secure the result for commercial purposes is a long though not very complicated process. Before the synthetic production of indigo could be attempted, an exact analysis of the natural indigo had to be known, not only as to its molecules, but as to the arrangement of the molecules among themselves. The synthetic production of indigo had proved a far greater puzzle than that of alizarine. The first step as to the constitution of indigo was made as far back as 1840, when Fritsche showed that aniline could be obtained from indigo. After some intermediate step, it was found a crystaline body, to which the name of isatin was given, was obtainable from indigo, and then in 1878 it was found conversely indigo could be obtained from isatin. There are three processes now known for obtaining indigo from isatin, but two of these are too costly to be of commercial value. Baeyer's process seems, however, to be even more then promising—to have established itself. He started with cinnamic acid from oil of bitter almonds, but this was two costly. Dr. Caro and Mr. Perkins have discovered how to obtain the cinamic acid from tolvene—a coal-tar product. From cinnamic acid, however obtained can be produced an acid complex in character, and to which a name. descriptive of its composition is given—ortho-nitrophenyl-propiolic acid The artificial production of indigo many even now be said to be within measureable distance for commercial success, for the ortho-nitrophenyl-propiolic acid (called for short propiolic acid), the colourless substance which on treatment with a reducing agent yields indigo-blue, is already in the hands of the Manchester calico printers, and is furnished by the Baden Company for alkali and aniline colours at the price of 6*s.* per pound for a paste containing 25 per cent. of the dary acid. With regard to the nature of the competition between the artificial and the natural colouring matters in the first place, the present price at which the manufacturers are able to sell their propiolic acid is 50*s.* per kilogramme. 100 parts of this can only yield according to theory 68·58 parts of indigo-blue, so that the price of the artificial (being 73*s.* per kilogramme) is more than twice that of the pure natural colour. Hence competition with the natural dye-stuff is not to be thought of until the makers can reduce the price of dry propiolic acid to 20*s.* per kilogramme, and also obtain a theoretical yield from their acid. This may or it may not be some day accomplished, but at present it will not pay to produce indigo from nitro-phenyl-propiolic acid. Nevertheless, a large field lies open in the immediate future for turning Baeyers's discovery to practical account. It is well known that a great loss of colouring matter occurs in all the processes now in use for either dyeing or printing with indigo. A large percentage of indigo is lost in the "cold vats" in the sediment. Another portion is washed off and wasted after the numerous dippings, while in order to produce a pattern, much indigo must be destroyed before it has entered into the fibre of the cloth. Moreover, the back of the piece is uselessly loaded with colour. The proper way of looking at this question at present is to consider ortho-nitro-phenyl-propiolic acid and natural indigo as two distinct products not comparable with each other, inasmuch as the one can be put to uses, for which the other is unfitted, and there is surely scope enough for both. Still, looking at the improvement which will every day be made in the manufacturing details, he must be a bold man who would assert the impossibility of competition with indigo in all its applications, for we must remember that we are only at the beginning of these researches in the indigo field.—*Times.*

ORANGES.

FOR a time in England the orange was not—we must go back far into the mists of antiquity. As early as the year 1290, it is recorded that seven oranges (*poma de naranja*) were landed at Portsmouth from the cargo of a Spanish ship, but for two centuries after that there does not appear to have been any particular commerce in them in this country. Then they became an important item in our imports, Billingsgate being then, as now, the great landing place for them. The Chinese claim the orange as a native fruit, and though, as Mrs. Bayle Bernard points out in "Our Common fruits," there being no reference to it in the travels of the accurate and observant Marco Polo has led some to doubt this, yet it is more likely that he may have overlooked or forgotten it than that it should have spread so widely there, and no record remain of its introduction, had it been transplanted thither. So thoroughly, too, was it formerly identified with that country that the sweet fruit was once universally known in Europe as the Chinese orange, and it still bears that name in America and even in India. A large part of our present supplies comes from the Azores: but Spain, Portugal, and Sicily contribute immensely, and send us their crops earlier than do the Azores Islands. Paricularly large is the importation from Valencia, which is one of the busiest seaports and the most thriving of Spanish cities. But the Azores, and especially St. Michael, the largest of the group of nine islands, furnish us not only with vast quantities, but the fruit is of a superior character, though we often get other oranges when we innocently buy what are represented to be "Sweet St. Michaels." From this island there is a regular trade by means of steam vessels, each carrying 10,000 boxes or more, and their arrival in the neighbourhood of Billingsgate creates a busy scene; the porters with huge "knots" on their heads, going to and fro as fast as they are able between the vessels and the fruit brokers' warehouses in Pudding-lane and the surrounding thorough fares, where the fruit is sold by auction three or four times a week.

At a meeting of the Adelaide Gardeners' Improvement Society, the longevity of the orange tree was discussed.

Mr. J. F. Pascoe said that in view of the great importance of the cultivation of the *Citrus* tribe in this colony there need be no apology made for dealing with the matter at considerable length. There were large areas now being cultivated with oranges, and we were beginning to export the fruit, which was acknowledged to be of superior quality. In Sydney our oranges had obtained a special first prize, whilst the Sydney-grown fruit had only been awarded an ordinary prize. If the orange trees would only live for the short period assigned to them in this colony, viz., about twenty to twenty-five years, it would not pay, for during the first five years the tree born no fruit, during the next five they produced very little, and if during the next ten or sixteen years they bore abundantly, the crops would scarcely recompense for the long period of unproductive cultivation. Before we got really good thin-skinned, good flavoured fruit, the trees must have acquired age, and therefore the early death of the trees through the ravages of disease could not be regarded in any other light than as a national calamity. Mr. M'Donald being a man of experience in gardening, and holding a position of influence among gardeners, had done some good by disputing the longevity of the Citrus tribes and there was no doubt that still greater good would be gained by a discussion of the whole question. Most probably Mr. Robinette had hit at the foundation of the evil when he suggested that it was due to the stock upon which the sweet orange was grafted. If seeds were taken from fruit raised upon sickly trees or those which were weakened by any cause, and the seedlings were afterwards grafted, it might be that the trees grown this way would be shortlived. But Mr. M'Donald did not seem to notice that there is a difference between natural decay and decay caused by disease, and, in opposition to the facts adduced, still made a pretence of clinging to his idea, ignoring the statements of some of our most eminent botanists and horticultural writers and pinning his faith to so much of one person's statement as suited him—that of Don Jose do Canto whose remarks were made with reference to the orangeries of the district of all others most liable to the attacks of the disease. If that gentleman's very able letter—or so much of it as they had been favoured with—were carefully read without prejudice, it would be found to bear out, literally and generally, all that Mr. Pascoe contended for; and if they followed the course adopted at the Azores instead of quietly watching the destrubtion that was going on, and bemoaning their fate they would stand a chance of obtaining the same result. The fact of Don Jose de Canto's letter were as follows:—Until 1836 the orange tree budded, blossomed, and fruited with unvarying regularity. The grower would as soon have suspected the sun of variation from his diurnal course as the orangeries from their yearly round of duty. They were handed from father to son, and, lasting as they did from generation to generation, it is not surprising that they became a symbol of permanence. These trees cost the growers no care, no attention, no labour, save the labour of picking and packing, so far as we can understand. The people might dance and drink the year round and the orange would blossom and fruit the year round without trenching without manuring, without draining;—it may be without pruning. The plant was neither fickle nor fastidious, and the islanders rejoiced in their orange trees. Suddenly, however, there came a change. This bright picture of the growing green-leaved, self-contained tree, surrounded by a joyful, sun-loving, dancing people dissolved away, and gives place to a pale-leaved and sickly tree, surrounded by a care-faced and inquiring population. Their first proceedings were those of the panic-stricken, they were carried to extremes. From absolute indolence they rushed into alarming activity; but it was the blundering activity of ingorance. Having had little need to inquire into the physiology of the plant, or the relations subsisting between the soil and the plant, they adopted measures to set things right which outraged both, and only made things worse, but gradually, by the aid of the suggestions of science and a teachable disposition, a middle course was hit upon, and restorative processes were prescribed with an intelligent knowledged of the patient's requirements. At first the trees were overloaded with manure and stifled with shelter and a great deal more was done to them than they well could bear. Now they perceive that thorough drainage is at the foundation of successful orange growing; that next to this, trenching to a great depth is essential, and, thirdly, that manure must be applied—but with discretion. It is true the trees are more fickle than they were, and die more frequently, and the fruit will not keep so long. But growers can again count with tolerable certainty upon their crop. The disease of the orange was first discovered in the Azores in 1836, when it was found that the oldest and best trees, as much as 200 and 800 years old, and producing each 6,000 to 20,000 oranges, were disappearing. It was observed that all the trees affected produced a very heavy crop the very year that the disease manifested itself, that the leaves became yellow and fell off in great quantities, and on the trunks or stems near, and sometimes beneath the ground; the bark opened, and drops of a kind of yellow gum exuded. The drops resemble tears (*lagrimas*, in Portuguese), and therefore the disease was named *lagrima*. Many orangeries were quite destroyed, and a remedy was eagerly sought. Opinions as to the cause of the disease were much divided Many thought it must be that the orange-tree had a limited period of existence, and this being reached, the tree must thus naturally decay. As we then only propagated trees by layers, this explanation was not thought to be unreasonable, but afterwards it was found that seedlings were attacked in the same way. Then it was found that superabundance of moisture in the soil was one o the worst conditions for the disease. Soon it was discovered that the destruction of the diseased bark and wood in the stem of the trees was the best method to save it. From February till August a skilled horticulturist visits every tree, and at the slightest sign of exudation of gum he cuts the bark across to allow it to run out. If the disease is in an advanced state, the bark and the whole of the diseased wood is cut out, the roots being bare to a distance of a foot or two feet from the stem, every portion of diseased root being cut away. By this means the tree is cured of the disease is found at an early stage; if not, it is dug out and a fresh tree put in from a reserve which is always kept for such contingencies. Although the disease still continues, the gardens now look very prosperous, for the remedy is known . . . . So we are returning to the old traditional culture. We are clearing the shelters, pruning the interior of the trees for the admission of air and light, are less libdral with manure, and keep the ground free of weeds, except when we want to excite vegetation. We have abandoned propagation by layers, and graft good chosen kinds upon seedling stocks. For shelter we prefer trees with their foliage, and take care not to let them grow too high. From these abstracts of the contents of the letter referred to and the leader, it would be seen that in the Azores for hundreds of years they had grown the orange successfully and without trouble, and previously to the outbreak of the disease *(lagrima)* they had trees 200 to 800 years old, producing immense crops of from 5,000 to 20,000 each. In 1836 the disease broke out, spreading consternation and ruin but remedies were discovered in time, and in 1868, when Don Jose de Canto wrote the disease, though still existent, ceased to cause uneasiness; and although the fruit was inferior to that formerly produced, confidence was restored, and growers were "returning once more to some of the old traditional culture." It certainly appeared a strange method of reasoning to endeavour to prove by the statement made in the above letter that the orange was a short-lived tree. The opinion ventured that those trees which have attained great age have got into places particularly favourable by Nature and circumstances was a most important one, and contained the very gist of Mr. Pascoe's argument. Nothing he could say would more fully sustain it. It was a well-known axiom, "Like causes produce like effects;" and knowing as they did, not only single trees but groups and plantations, of vast age and in great vigour, it was their duty and (with present prospects) necessity to inquire into the attendant circumstances with a view of remedying existing evils. The idea that the genus citrus had lived its allotted time, and had so degenerated that its course might be said to be finished, seemed to him too ridiculous for consideration, and totally opposed to all theories of rise, progress, and decay that he had ever met with. It was a very convenient doctrine for

Greeks and Mahomedans, and those who believed "Whatever is, is right," or were too indolent to investigate causes. Disease in fruit trees and fruit-producing plants was of common occurrence, and the *Citrus* family did not stand alone; but perhaps of all the fruit trees they were acquainted with they had enjoyed less opportunity of studying the nature and habits of the orange than that of any other. The culture of it in its natural habitat was unknown to them, and its natural age was so great that they could do little in a generation; but, having it in their midsts they must study its nature and treat its diseases as they studied the nature and disease of other fruit trees. When the odium broke out in France, the people did not stand idly bemoaning their loss, nor did they imagine the vines had lived their time, but they searched into the character of the disease, and found a remedy by which we at the present day benefited. The "American blight" attacked the apple trees, but the gardeners found out in time that the aphis could be beaten, so far as the roots were concerned, by grafting upon "blight-proof" stocks. The apricot, peach, plum, almond, and other trees were subject to fungoid growths and encroachments, but gardeners found a remedy in sulphur, &c. So with respect to the orange, a careful study of the subject, with careful observations of all the conditions, would be very interesting, though perhaps slow; but in time a fact would be discovered here, and something from there, until a mass of information would be gathered which would enable them to cultivate the orange as successfully as any other fruit tree. That our orangeries were seriously diseased was an admitted fact—from every district in which trees were planted came the same story. One by one they were losing their oldest and best orangeries, and many of those newly planted were looking very queer, but so little attention had been paid to the subject that they could not even tell what the disease was, or give any definite idea of its cause. Its effect they all knew too well, but as far as he was aware, no one had made any systematic attempt to cope with it. Several, for very shame's sake, had made pretence of doing something, but, having no definite object in view, had accomplished nothing. He thought their attention should be chiefly directed to the nature of the soil, the method of production, treatment during early stages of growth, and manner and time of watering. As regarded the first, Risso told them that at Genoa and Florence they were grown in a strong yellow clay, richly manured; this was considered by Italian gardeners to be best suited to the orange tribe. He also said that in France clayey loam, rotted vegetable matter, and rotted horsedung were considered the best compost. Our ideas as to a suitable soil were quite opposed to this, and we sought a sandy loam with a gravelly subsoil. In his (Mr. Pascoe's) opinion some most radical changes and improvements must be made in the method of production. It was his firm belief, after carefully watching the matter for years, that the stock they worked upon was the chief cause of the mischief—in fact he had seen the stocks of one-year old trees as they came round from Sydney so bad with disease that it seemed a sin to sell them for planting. The question then arose, how were they to propagate. Layers were generally condemned—how deservedly he was in doubt; the stocks in present use they knew to be bad; then what must they use? Experience only would tell them. Miller recommended citrous: London citrous and Seville oranges, and he had heard experienced horticulturists recommend the poor man's orange and the shaddock. His advice was to try them all, though he believed the Seville would be found the best stock the orange family could be worked on. Mr. Moore, of Sydney, during his investigations into the nature of the disease in Europe, found those trees worked on Seville stocks to be almost free from disease, and it is a noticeable fact that the great majority of those trees in Spain now flourishing and from 600 to 700 years old are Seville, and were planted before the sweet orange was introduced into Europe. The treatment of the tree when young was of vast importance. That any tree should be pampered and forced, or allowed to produce heavy crops when young, was totally opposed to all physiological laws, and Lindley said the abstraction of fruits and flowers augmented the vigour of the branches, or of the parts in connexion with them, and that the removal of any part which takes up a portion of the food employed in the support of the flowers increases their luxuriance. The manner and time of watering Mr. Pascoe would leave to men more practical than himself. They were told on good authority that the *Citrus* family did not like coal or excessive moisture; but to see the way in which they were inundated sometimes, one would almost imagine they were semi-aquatic plants.—*Journal of Applied Science.*

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Monthly General Meeting was held on Thursday, the 23rd June 1881.

W. H. COGSWELL, ESQ., President, in the Chair.

The Proceedings of the last monthly Meeting were read and confirmed.

The following Gentlemen were elected Members:—

His Grace the Most Rev. Dr. S. Goethals, Baboo Shamlall Sen, Lieut.-General Umbur Jung Bahadoor Rana, Messrs. A. A. Shircore, S. Gowan, Edward Cleveland, W. E. Crum, H. M. King, D. Cruickshank, J. H. Barry, W. Palmer, C. H. Moore, Dr. D. O'Brien; Managers, Debroghur Division, Upper Assam Company, and Blackburne Tea Garden, Assam.

The names of the following gentlemen were submitted for Membership:—

A. W. Hurle, Esq., Serajgunge,—proposed by Mr. J. G. Mougens, seconded by Baboo P. C. Mittra.

J. E. Weingartner, Esq., Locomotive Department, Saidpore,—proposed by Mr. T. Walton, seconded by the Secretary.

The District Engineer of Jessore,—proposed by the Secretary, seconded by Mr. G. L. Kemp.

Baboo Rakhal Dass Holdar, Manager, Chota Nagpore Estate, Ranchi,—proposed by Baboo P. C. Mittra, seconded by Baboo P. C. Ghosa.

Cunningham Hudson, Esq., Merchant, Calcutta,—proposed by Mr. W. H. Cogswell, seconded by Mr. W. Stalkartt.

The Manager of the Rungting Tea Company, Darjeeling,—proposed by Mr. Albert Smallwood, seconded by the Secretary.

Baboo Amrita Naryan Acharjea Chowdry, Mymensing,—proposed by Mr. R. de Dombal, seconded by Baboo P. C. Mittra.

Captain W. H. M. Francklyn, Toughoo,—proposed by the Secretary, seconded by Mr. S. H. Robinson.

Rejoined,—T. F. Hamilton, Esq., Merchant, Calcutta,

CONTRIBUTIONS.

1. Records of the Geological Survey of India, Vol. 14, Part 2. From the Government of Bengal.
2. Report of the Committee of the Bengal Chamber of Commerce for half-year ending 30th April. From the Chamber.
3. Introduction to the annual accounts of the Sea-borne trade and navigation of the Bengal Presidency for 1880-81. From the Collector of Sea Customs.
4. Journal of the Asiatic Society of Bengal extra number to Part 1 of 1880; and Proceedings for April 1881. From the Society.
5. Seed of *Reana luxurians.* From T T. Allen, Esq.
6. Seed of *Pinus longifolia.* From the Superintendent, Botanic Garden, Saharunpore.
7. Seed of *Pithecolobium saman* (Guango.) From the Agri.-Horticultural Society of Madras.
8. Seed of the Carob tree (*Ceratonia siliqua.*) From the Agri.-Horticultural Society of the Punjab.
9. Sorgho seed of the red variety (*Sorghum saccharatum.*) From the Director, Department of Agriculture, N.-W. Provinces.

The above seeds are available to Members.

10. A small collection of Orchids and seeds from the Andamans. From O. H. Brookes, Esq.
11. Specimen of *white* gram and sunflower seed. From R. Nicholson, Esq.

GARDEN.

The following are extracts from the Superintendent's monthly report.

"The weather has been propitious for propagation. Advantage has been taken of the early rains for gootying and grafting in the Orchard, and I anticipate the garden will have sufficient grafts to meet the increasing demand for this class of plants.

Our stock of beautiful and rare plants having attained sufficient growth, are now being propagated from, and I hope that at the close of the rains, they will be sufficiently augmented to meet general demands. There are many beautiful plants available for issue in the garden, but they are so numerous, that I fear it would make this report too lengthy to include them in it.

Manure experiments.—The following have been sown.—Maize, bajra, sun, dharus, in the economic portion of the garden, under the same conditions, as at the experimental farm at Bangalore; the seed has germinated well, and in due course will be reported on.

Over half an acre of ground is now planted out with American maize seed, acclimatized at Nepal, and presented by Mr. Girdlestone last year to the Society.

This seed germinated well, and the plants are looking vigorous and healthy, and will be fully reported on hereafter.

Panicum spectabile.—Raised from seed, occupy a small plot in our economic garden, and are making vigorous growth.

The greater portion of the sheds destroyed by the storm, has been re-erected, but has somewhat interfered with ordinary current work; it is a now desirable that Members should indent for their annual supply of plants so as to make room for fresh propagation. The two tanks are filling rapidly under an improved system of drainage. The tank at the west entrance being higher than it was after the rain last year, we may hope to have a full supply of water for next dry season.

I would draw attention to the large supply of useful plants now available for issue, among them Teak *Casuarinas* and *Inga saman.* Also to the very large quantity of Arabia Coffee seedlings. Stock of Rose plants available and are varied and considerable, also Crotons. The garden has now in addition to its previous collection of Orchids, a fair number of *Vanda Giganteum, Vanda Lowii, Dendrobium Dalhousinum, Cypripedium,* &c. Also a considerable quantity of *Memecylon tinctorium;* this charming plant when in bloom has its branches covered with dense clusters of cerulean blue flowers of a pleasant perfume. I may add that one of our *Agaves* has flowering spikes on it, affording a good opportunity for any Members desiring to make a hedge.

Having succeeded in forwarding a parcel of violets per post to Simla which is reported to have arrived in splendid condition, I think I may safely venture to say, that for the next six months at least, this method, if adopted for Mofussil members in remote stations, and not over a week's transit, will enable them to realize their full privileges which to a great extent has hitherto been either permitted to lapse, or given to friends in Calcutta. Crotons, Coleus, Palms, and many other plants in their infant stage can be specially packed; the postal charges are trifling.

The multiplying power in propagation of plants in this garden is unlimited and with the minimum of cost in transit thus suggested, a fair outlet for plants from this garden should be created, the interests of Flori. and Horticulture advanced, and the very natural sequence of an increased demand, the lowering of expenditure, *pro rata,* in disbursement of plants.

The garden servants have enjoyed special immunity from fever during the period that it was raging in the neighbourhood; I encouraged them to eat the green papaya cooked as a curry, the men being permitted to take the fruit from the garden gratis.

The Lady Superior of St. Vincent's Home informs me that since she has planted Neem trees "Azadirachta," in her grounds, the inmates have been specially exempt from fever; there is no doubt this plant possesses fever dispelling properties, and as the seed can be procured for the gathering in Calcutta, the experiment of planting the same in the fever districts is worth trying. The plant is easily raised and needs no special care."

In connection with the virtues ascribed to the "neem," tree in the above report the Secretary drew attention to the fact stated in O'Shaughnessy's *Bengal Dispensatory* that Dr. White, of Bombay, used the bark of this tree as a substitute for Cinchona and found its success nearly equal as a febrifuge remedy. He further submitted a note from Dr. D. O'Brien, of the Sobeating Estate, Debrogurh, applying for seeds of *Eucalyptus rostrata.* Dr. O'Brien states that he raised some plants of that variety five years ago, and they are now 25 to 30 feet high, but very slim. "They were planted about the compound of my bungalow and to these trees I must attribute our complete freedom

from fevers, although the people (coolies) about are very subject to fevers."

Exhibition of Models of Agricultural Appliances.

Read a letter from the Secretary to the Government of Bengal, dated 11th May, suggesting that the Society undertake the formation of a collection of models and drawings of Agricultural appliances for which the Lieut.-Governor is willing to grant a sum of Rs. 500. The Society having previously agreed to grant space for such exhibition.

Read also a preliminary report from a Sub-Committee of the Council stating what in their opinion would be the best mode of meeting the wishes of Government.

Resolved, that a copy of this report be forwarded to Government in reply to the Secretary's letter.

Trial Shipment of Fruit from Melbourne.

The Secretary next submitted an interesting and useful memorandum, prepared by Mr. James Inglis, Executive Commissioner for India, at the recent Melbourne Exhibition, copy of which he had been favored by the Hon'ble A. B. Inglis, of this city.

The following are extracts from this memorandum :—

" In previous papers issued from this Court by Mr. Buck on the subject of the export of Australian produce to India, it has been noted, that in any dealings on a large scale, it is of little use to study the requirements of the European residents. The wants of the natives must be ascertained, and if these can be met, the trade is worth consideration.

Fruit of all procurable kinds is greatly in demand by the natives of India, especially in the northern parts, where fruit is scarcest ; and where there is a numerous middle class who can afford to buy it.

Large quantities of apples used to be brought to Calcutta by the Ice ships from America. The multiplication of Ice machines of late years, has somewhat checked this supply : but there is still the same demand as formerly.

Apples dried and fresh, dried apricots, figs, raisins, pistachios, almonds, walnuts, pomegranates, and grapes, &c. are imported from Afghanistan. Dried fruits and nuts in the largest quantity. The cost of carriage is great, as hundreds of miles have to be traversed by camels who carry the fruit.

The statistics for importation from Cabul and Candahar, taken from the Inland Trade Returns, are about £ 1,20,000 worth yearly.

The price of apples, of smallish size, at Cawnpore, in the centre of Northern India and in Calcutta is about a rupee, or from 1*s.* 6*d.* to 1*s.* 8*d.* a score. The grapes are of a long whitish kind, with thickish skins, very sweet, and they are packed in round chip boxes, three rows to each box. Each grape is cut from the bunch and laid separately on layers of cotton wool. In this way they bear long journeys, a large percentage keeps good for months, and they sell in Calcutta at an average of about a rupee per box. I estimate each box to contain say about 100 grapes.*

It is proposed by Mr. Buck, Director of the Department of Agriculture and Commerce, N.-W. Provinces and Oudh, and president of the Indian Committee for the M. I. E. to send for India to the Horticultural Society of Victoria, samples, prices and other information of all the fruits imported ; and the information thus obtained will doubtless appear in the Society's annual report.

The apples are being packed in different ways, and the present shipment is in fact purely an experimental one, with a view to gather useful hints from the result whatever it may be. Every method and every season should be tried : say by following this up with small shipments monthly, until the right plan and right season are definitely ascertained. Dried fruits especially should be tried, and the best mode of drying should be ascertained by experiment."

The Secretary also read a brief memorandum which he had drawn up on the above to the following effect :

" Having been invited by the Hon'ble Mr Inglis, of Messrs. Begg Dunlop & Co., to be present at the opening of the boxes containing a trial shipment of apples and pears, I think it may be useful to put a few remarks on the subject on record.

This shipment was, unfortunately, through a misapprehension of the P. and O. Office, allowed to remain for 14 days or so at the Jetties, so that seven weeks had elapsed after its despatch from Melbourne before the boxes were opened and hence they arrived under adverse circumstances. Notwithstanding this delay one-third of the contents was, apparently, in good condition, and a larger proportion would have, doubtless, reached in fair order had a better system of packing been adopted. The present mode of packing in closed up boxes, layer over layer, a dozen or so deep, is very objectionable. A much better plan would be to pack in baskets slung up in the inner deck of the steamer, or better still, (if not found to be too expensive) in crates somewhat in the same fashion as eggs are imported in such large quantities from France into England. If the fruit were carefully selected and carefully packed in the manner proposed, at least 75 per cent. should reach in good condition, as the passage from Melbourne to Calcutta occupies so comparatively short a time. Care should also be taken in sending the best kinds of fruits. The apples and pears of this first trial consignment which I tasted were of an inferior description, the former not better that what used to be imported in ice ships from Boston.

In connection with the above I would beg to call to the notice of the meeting the fact of a small experiment in this way in January 1878, by a Member of the Society (Mr. S. H. Robinson.) Mr. Robinson brought out on the Khedive a hamper full of apples from Devonshire of the ribstone pippin and flatnosed pippin kinds, both keeping or store apples. In this hamper 60 were brought, lightly packed in the hamper each in separate pieces of paper. After a voyage of 6 weeks two only had decayed, and 4 were somewhat bruised : the rest were all good and retained their flavor fairly. The hamper was kept in the cabin the first two weeks of the voyage, and for the rest of the voyage was kept cool in the ship's ice room but not in the ice."

Introduction and Distribution on an Extensive Scale of Seeds of Certain Kinds of Field Crops.

Submitted various recent communications from Captain J. F. Pogson, of Simla, in respect to the introduction from other countries for distribution of seeds of certain field crops, of which the following are extracts :—

" Now that official attention has been turned to the improvement of Agriculture, Government should, I think, take up the important subject of importing certain of our field crops. For example from Benares to Meerut, the early ripening varieties of Indian corn should be imported from America. Then there is the early yellow Canada, ditto yellow Dalton, early Compton and other early kinds. Then for all districts north of Meerut later varieties would suit, and from Umballa on to Peshawur the latest ripening varieties of maize. The produce of such seeds would realize the same price in London, as the price of American grown corn. I enclose a half page cut out of " Buists Almanac and Garden Manual," for 1880, received in the box of his seeds. This Golden Millet, and the others are, I believe, unknown in India, and might also be introduced for field culture. We also want superior varieties of barley, and especially those which when properly prepared yield pearl barley.

In a second communication of 1st June, Captain Pogson continues the subject :

" We all know, that no improvement in Agriculture is possible, without an improvement in the variety and quality of the seed sown.

Our wheats are all good, and where from bad soil the grain has degenerated, a change of seed, and the use of manure, would at once put matters to rights.

But our maize and millet grain have greatly degenerated, and fresh seed from America is most urgently needed to rectify this serious defect. This introduction of seed, I hold it is the province of the Government to supply.

I submit that too much stress cannot be laid on the subject of introducing early, second early, middle, and late varieties of maize. The object in view being to have a variety of this most valuable cereal, which will ripen in the locality of its introduction, at the same time, as does the inferior indigenous maize, so that the ground may be cleared for the wheat, barley, and other cold weather crops. In the northern parts of the Punjab, the late ripening maize of America would be a positive boon, and bring very considerable wealth to its cultivators. From Jullunder to Meerut, the middle ripening varieties would suit, and yield like results, and so on, going eastwards till Bengal is reached.

Let us take gram, (*Cicer Arietinum*) as the next crop to be improved. Few officials in the governing circles of Simla, N.-W. Provinces and Punjab, know that very large quantities of gram are consumed in Italy, and I believe in all Roman Catholic countries ; (France, Spain, Austria, &c.), as human food, egg curry with gram dall may be considered fasting or mortifying diet. But I know few dishes more tasty. Leave out the curry condiments, and you have an egg stew, or as we would call it, " Egg Kormas and Gramdall."

Answer. Want of seed which Government should at once introduce. Mr. Nicholson has demonstrated that it (*white gram*) will grow in Mirzapore as well as the inferior kind, and to continue the cultivation of the latter is by no means desirable.

This undeniably superior gram, (it tastes like pea, and gram combined,) would, as a matter of course, command a very much higher price in all markets, and the producer would at once be benefited. But the hands of the Collector of Mirzapore are tied, and he cannot purchase such seed gram from Mr. Nicholson, and so the improvement cannot spread.

Let us now turn to the Punjab. From Delhi west-wards, gram is very extensively cultivated, and a good deal is sent down the Indus, and from Kurrachee is shipped to Mediterranean Ports. Trieste being the principal one.

We are supposed to be on friendly terms with the Court and people of Cabul : and it follows that if the money be forthcoming, (say Rs. 1,00,000, £10,000) that no difficulty would be experienced in obtaining seed gram from Cabul and closer, for all we at present know to the contrary.

The Punjab Agriculturist would at once cultivate the white gram, the seeds being given free, and the only clause being, that the recipient must retain sufficient seed for next year's sowing. To encourage extention of this cultivation for five years, prizes of turbands should be offered, and silver bangles for every ten acres of land, placed by any individual zemindar, under Cabul gram. Thus 100 acres would entitle to ten bangles and a pugree of honor.

Rice is another grain which should be looked to, and I fear we sent to the wrong place for it. Carolina rice does not suit India, and should try China and Japan for first class seed rice. In Japan they cultivate a variety of rice, so rich in oil, or fat, that the Chinese will not eat or use it. Now this rice would suit the Hindoo exactly, who would have naturally buttered rice to eat, with his plain boiled dall. For the London Market the seed rice of China would yield the proper article, much starch in the grain is needed, and I think the Chinese kind would yield the full supply.

In a third letter of 15th June, forwarding a specimen, Captain Pogson offers the following remarks :—

" By this-day's bangy post, bearing, I have sent you a half pound sample of a superior variety of barley, sown by me in October, 1880, and harvested on the 28th of May 1881. I have also sent three ears of this barley, so that a satisfactory inspection and opinion may be formed as to the quality and commercial value of this particular description of barley.

In 1880, Mr. Nicholson, of Mirzapore, was so good as to send me some of this barley for sowing, and stated in his letter that the native Agriculturists held in great estimation, and were anxious to obtain such seed barley for cultivation.

Mr. Nicholson did not mention whence he obtained the original supply of seed, so I cannot tell whether it is Indian, or from the Continent of Europe.

My fowls, eat this barley with avidity, but they won't touch the common barley, thus as far as feeding poultry goes, the variety is a desideratum.

To test its value as human food, I had some ounces half roasted in a pan, (coffee bean fashion) and *quantum suff* put into the soup. The

addition made it excellent, thus taking the place of "Pearl Barley." The imported "Pearl Barley," is much too costly for ordinary use, and British troops, I believe, regard it as a hospital luxury. Now if the proper description of mill was forthcoming, this variety would supply all classes with indigenous "Pearl Barley," at a very cheap rate.

I have preserved my entire crop for use as seed, and will with pleasure place it at the disposal of the Council of the Agri.-Horticultural Society for distribution to Members, and all who may feel disposed to cultivate it, and thus secure a good supply of seed for sowing in the cold season of 1882.

From its appearance, I am inclined to think, that it should be called "*Barley wheat*," the Hindee term "*Gae jow hoon*." is perfectly applicable, and would be the popular name *Gae jow hoon*.

Mr. Nicholson has shown, that it is as easy to grow superior barley in the plains, as the inferior kind, and when this truth dawns on the native Agricultural mind, the cultivation of the common barley will be abandoned.

If Tea Planters who are Members of the Agricultural and Horticultural Society would this year import seed of the "Hordeum Zeocriton," of the United Kingdom, the cultivation of this barley would soon lead to the manufacture and export of superior "*Pearl Barley*," and the new industry would especially benefit the Agricultural classes. The seed raised in the Himalayas, would answer perfectly in the plains, whereas imported seed sown in the plains, would, I fear, be a failure, the change of the climate being so very great.

I will in due course let you know how much seed barley I possess at present, the gram has not been removed from the ear.

The Society might import the kind of mill used for converting seed barley into *Pearl Barley*, and its exhibition would lead to numbers being imported by the trade."

The specimen of barley was much admired. It was agreed to import the mill in question, as suggested by Captain Pogson, and included in the proposed collection above alluded to.

In connection with the foregoing the Secretary, when calling attention to the two specimens of *white* gram (a seer of each) on the table, referred to a letter from Mr. R. Nicholson, of Mirzapore, the donor of which the following is extract :—

"I have been growing white gram for the last six years, but not to any extent as I feed my cattle on oats. I originally got it from Mr. Nickells of Benares. He told me he got it from the Maharajah of Benares. From the want of rain, I fancy the quality of the gram has greatly deteriorated this year. Both specimens now sent are from this year's crop. No. 1 is the fine good grains that were picked out."

The gram specially No. 1 was considered very superior to the ordinary gram and that its cultivation should be extended.

The barley I sent to Captain Pogson was raised from a handful of seed given to me by one of my servants some five or six years ago, he told me a man coming from Benares he believed gave it to him.

As I have a limited piece of land I have only sown a little ground to keep up the seed. Two years ago I gave two seers to one of my native officers who lives in the Jounpore district. He tells me that from his first crop he gave seed to some of his friends and that the grain is much prized, and he gets many applications for seed. He also told me the meal made from it was very superior and that the *chapaties* made from it were quite as good as from wheaten meal.

It yields much more meal than the same weight of the best native barley, and there was little loss of weight in grinding it as the proportion of bran was trifling.

Last year I sent seed to Mr. Peppé of Birdpore, in the Bustee District, he wrote to me he had a fine crop, and expected to be able to sow at least four beegahs this year, he also said it was much esteemed by his ryots, and that the only objection he saw to it was that as soon as it was fully ripe the seed-shed very much but he hoped to prevent that this year by cutting before it was over ripe.

As referring to the subject before the meeting, the Secretary drew attention to an application just received from a gentleman in Oude for a large quantity of good oat seed which he wished to raise there with the view of introducing a superior description. Such applications were constantly received not only from Members, but other residents in various parts of the country. The Society annually imported seeds of field crops, such as wheat, barley, oats, clover, lucerne, maize, cotons, tobacco, &c., but as its means would not permit of a large sum being appropriated to such purpose, it could only meet such applications on a limited scale.

On a review of the whole subject, there was a feeling in the Meeting that the introduction annually of good varieties of seeds of field crops, on a large scale, was a matter well deserving of the attention of the Government of India in its Agricultural Department.

POTATO CULTURE.

Read a letter from Colonel H. R. Wintle, of Futteegurh, dated 6th June—"Regarding the potato [from Melbourne stock] you sent me"—observes Colonel Wintle—"I am afraid I must say they proved a failure with me. I sowed some whole and some cut up; the produce was not satisfactory in size or quantity. Out of the 11 seers put in I only got 9¼ seers. I have kept them for seed, they are all sprouting and shall put them in again in October, and perhaps the yield will be better.

The finest and best crop of potatos I ever had, was from a packet of potato seed I had out from Sutton and Co.s I sowed the seed broadcast, the produce was small potato of the size of marbles weighing all about 14 seers. I kept these and the following cold weather put them in, and the yield was, as I may say, the finest and best crop I ever had weighing, I should say, about 12 maunds. The price of the packet of seed was 6 pence."

The Secretary intimated he had requested Messrs. Sutton to send a few packets of the same seed for distribution to Members desirous of trying it.

MODE OF GROWING ANÆTOCHILI.

Mr. J. Coles Hardinge, the Honorary Secretary of the Agri.-Horticultural Society of British Burmah, gives in the following communication a mode of treating the Anætochili, which he has found very successful :—

"I see in the last published number of your Society's Journal (this year) a note by your Head Gardener about growing Æneotochilus, and his want of moss to grow them in. The climate of Calcutta and Rangoon is not very much different, so I think if he adopts my plan, he will be as successful in growing these beautiful plants as I have been.

I get shallow earthenware pans (about a foot in diameter) several drainage holes being made in them, these I fill with tolerably large pieces of clean broken brick and charcoal, sprinkling a handful or two of old rotten cocoanut husk powder, *i.e.*, the powder which falls from the husks when beaten), between the interstices of the broken brick. n this I lay the pieces of Æneotochilus cut into lengths of one or two inches (or more if there are many, during the rains, when they soon root and begin to grow, the roots firmly adhering to the pieces of bricks. In the rains, they are placed under a shed with an open trellis teak wood roof over which some creepers have been trained, they require plenty of light, but should be shaded from the direct rays of the sun, these plants stand any amount of *drip* which the generality of Orchids do not, and nothing is more fatal to many of them with large fleshy leaves such as *Vandas*, and *Phalænopsids*.

In the dry weather, they are kept in the same situation and watered daily, care must, however, be taken say in November, December, not to water them too freely or they rot off, the bricks and mould turning sour. Every year just before the rains I give them a fresh handful of coir dust, not "smothering" or covering the bulbs, they being left well exposed in December. January the leaves begin to get discoloured and fall, and their season of rest is between that month and April when they should be sparingly watered. I use no moss at all, for I have gathered these plants myself during the months of June and July, when it rains nearly every day, in the vallies about the hills on the Islands of Pulo Penang, Pulo Ramos; and others adjacent: their home is the deep crevices of damp boulders near running streams or where there is a constant steamy moisture from evaporation, where I found them in the greatest abundance, there was plenty of day light, but the rays of the sun could never reach them.

I may mention that last year Messrs. Hugh Low & Co.'s Orchid Collector while passing through Rangoon was quite struck with the size and hardiness of my plants, and he made a memo. of my method to take home with him for adoption in England."

COMMUNICATION ON VARIOUS SUBJECTS.

1. From H. Beveridge, Esq., C.S., Bankipore, states, with reference to the memorandum on Munjeet in the last Number of the Society's Journal, that it is cultivated in certain parts of the Backergunge district
2. From the Collector of Backergunge giving some particulars on the cultivation of Munjeet in his district.
3. From Captain J. F. Pogson, a note regarding *Gossypium arboreum*.
4. From Under-Secretary, Government of Bengal, further particulars regarding *Sida rhomboidea*, in continuation of the papers submitted at the March Meeting.
5. From the Secretary, notices regarding the flowering of Bamboos.
6. From Captain Pogson, particulars regarding the identification of wild strawberries in connection with recent papers respecting the efficacy of *Potentilla* leaves for cattle disease.

The above papers were transferred for publication in the Journal.

7. From the Deputy Commissioner of Sumbulpore, applying for seed of the Manilla hemp plant.
8. From the Secretary Agri.-Horticultural Society of Lahore, to the same effect and information as to mode of cultivation. (Information given, but plants not available.)
9. From the Executive Engineer, Cuttack, applying for information regarding culture of the Date tree, cost, yield of Sugar, &c., as he thinks it might be profitably cultivated in the Canal lands and banks of the Orissa district. (Complied with.)
10. From Messrs. Andrew Yule and Co., applying for information regarding the culture of the Maple at Darjeeling, in connection with a large supply of seed recently received by them from America through the intervention of the Society. (Complied with.)

MINERALOGY.

WE observe that the Government of Madras have resolved to grant certain privileges to parties "prospecting" for metals, and have passed the following resolution.

ADVERTING to the question of *prospecting* which, in the first paragraphs of the marginally noted Orders, the Government resolved to omit from consideration in framing leases for mining for gold and metals other than gold, it has since occurred to Government that some kind of temporary exclusive privilege may properly be given to prospectors who desire to test specific localities closely.

2. Ordinary prospecting does not, in the opinion of the Right Hon'ble the Governor in Council, require any special protection, but where prospectors have obtained promising indications, it may be reasonable to grant what may be termed "*proving*" leases for a limited time over a limited area to test results more closely, say for six months or a year, over half a square mile, though the area might be extended if the block was compact. This arrangement would afford reasonable facilities for testing before applying for a mining lease, and would protect intelligent and scientific research.

3. It is necessary that the area should not be excessive to avoid risk of excluding others who may have more *bonâ fide* intentions than the concessionaries.

This will be ample to protect *bonâ fide* prospectus, and is just one of the ways by which Government can help our new industries without resorting to the guarantee system.

GARDEN.

USEFUL GARDEN RECEIPTS.

(From Hogg's Gardeners' Year-book.)

TO MAKE PURE BLOOD MANURE.—The receipt for making this most valuable fertiliser for garden crops, flower borders, and pot plants, was given me by Sir Daniel Cooper, Bart., and may be relied upon as constituting a genuine artificial manure of great importance, and which can be made in small quantities as desired:—Muriatic acid, 4oz.; protosulphate of iron, 4oz.; blood, 16lbs. As soon as the blood begins to smell, pour upon it the muriatic acid and protosulphate of iron previously mixed, and it will be reduced to an inodorous powder, which will keep any time, and is of a fertilising strength equal to guano. The action of this manure is to produce flowers and fruit instead of leaf and stem.

PETROLEUM *vs.* AMERICAN BLIGHT.—I have been able to almost entirely get rid of that pest to my apple trees, American blight. Last year the trees were completely covered, but after the fall of the leaf I had them carefully dressed with petroleum, which was applied to the affected parts with a paint brush. Contact with the petroleum seemed to destroy the insects, and I was in hopes they had entirely disappeared. This summer, however, there have been signs of them again, but whenever the blight makes its appearance an application of the brush dipped in petroleum at once extinguishes it. The contact of the oil with the leaves and fruit buds apparently does no injury, and I see that with a little patience and perseverance my trees, which were in a fair way for being ruined can be preserved.—E. B.

TO CLEANSE FRUIT TREES OF MOSS.—Not only the mosses and lichens which so generally affect fruit trees, but the eggs of insects, may be effectually destroyed by dressing the trees in winter with a wash composed of a saturated solution of soft soap and common salt or brine. The trunks and large branches ought to be first scraped with a scraper made of old hoop or any other implement that may be improvised for the purpose, and when all the scales of bark are removed, apply the mixture with a painter's brush, working it well into the crevices. This is much preferable to, and not so unsightly as, washing with lime.

METALLIC PAINT.—To 40 gallons of Stockholm tar add 4½ gallons of naptha of about 18 deg. Baume, specific gravity, mix carefully, and let it stand for twenty-four hours; then draw off the purified tar mixture from the dregs, and to 40 gallons of this mixture add 30lbs. of dry ochreous iron ore, commonly called bog iron ore, in the form of a fine powder, which must be thoroughly incorporated with the tar; then about 40lbs. of commercial white arsenic and 100lbs. of oxide or sub-oxide are added, and the whole is reduced to a thick paint by a mill or otherwise.

TO REMOVE MOSS FROM LAWNS.—I have had lawns almost completely taken possession of by a thick carpet of moss, which has well nigh obliterated every trace of the grassy turf. After experimenting with every imaginable remedy, I have found nothing so certain as a good dressing of wood ashes. The effect is not immediate, but during the following summer the moss disappears, and a thick turf of fine grass with a profusion of white Dutch clover succeeds. In some parts of the country, where wood is not used as a fuel, it is sometimes difficult to obtain wood ashes. In this case the simplest way of procuring them is to collect all the prunings of hedges, shrubs, rough bushes, and other waste materials of a similar character that are to be found about most places, and burn them in a heap. Enough ashes will generally be got to supply the needs of the place.

TO DESTROY GRASS AND MOSS IN PAVEMENTS AND WALKS.—Dissolve 1lb. of powdered arsenic in 3 gallons of cold water, boil and keep stirring; then add 7 gallons of cold water and 2lbs. of crushed soda, stir the whole well whilst boiling, and with a rose watering pot apply to the walks in dry weather, from March to May inclusive being the best time. The above quantity will be enough for 25 square yards. An inclining board should be placed at the sides of the walks or grass to keep off the hot liquid. Salt will destroy weeds for a time. If you have box edgings, the salt or the soda and arsenical solution above-named must be kept from them, otherwise they will be killed.

TO SOFTEN OLD PUTTY.—The best application for softening old putty is caustic soda or potash—preferably the latter. To make either soda or potash caustic, dissolve them in water mix, with freshly burned and slaked lime, and after the mixture has settled, pour off the clear liquid for use. Putty will be very readily softened if kept moist with this liquid. Caustic alkali is also the best, and, in fact, the only thing that will remove paint spots from the glass of windows after they have once become dry. Or dip a small brush in nitric or muriatic acid, and with it anoint or paint over the dry putty that adheres to the broken glass and frames of your windows; after an hour's interval the putty will become so soft as to be removed easily.

TO REMOVE WORMS FROM LAWNS AND POTS.—Half an ounce of corrosive sublimate (bichloride of mercury) dissolved in 15 gallons of water will cause worms to come to the surface; but care must be taken that fowl do not eat them, otherwise they will be poisoned. A peck of freshly made quicklime mixed with 40 gallons of water, and allowed to stand till it clears, it applied through the rose of a watering-pot will have the same effect. These mixtures may also be used to remove worms from flower pots.

ORCHIDS FOR AMATEURS.

DENDROBIUMS rank among the very finest of all orchids. Most of the species which we named in the March number of the *Villa Gardener*, will grow well in the warm end of a Cattleya or intermediate house. They may all be grown either in pots or baskets, but those most fitted for basket culture are Chrysotoxum, Densiflorum, Devonianum, Parishii, Pierardii, Thyrsiflorum, and Wardianum. The others do fully as well in pots. Strong-growing kinds should have a good depth of material to root in such as nobile; weak rooters, such as Parishii, should have but little material.

The two great secrets in the successful cultivation of the Dendrobium are a decided season of growth and a decided season of rest. This is best secured by affording a pretty brisk heat from the time the growth commences, until it is fairly finished, and then the plants should be kept comparatively cool. During the growing season a plentiful supply of water is necessary, and during the resting period only just as much as will prevent shrivelling. It is only by such treatment that *D. nobile* can be made to yield a profusion of flowers. By keeping the plants warm and moist they go on growing, but flower only sparely; but by the opposite treatment abundant floriferousness may be had. The evergreen kinds should not be kept quite so dry as the deciduous kinds. During winter the baskets in which these are growing should be damped weekly with the syringe.

DISA GRANDIFLORA.—This is a very fine cool-house orchid, and when there is only such a house as we have recommended, it should be put in the coolest position possible, and near to a ventilator, for it must be borne in mind that too great a heat is against the plant's well-doing. The ordinary orchid mixture will suit it well. Some growers add a little very fibry loam, but we cannot say that it does better in it than in the ordinary mixture.

LÆLIAS.—Anceps and Autumnalis should be in the smallest collection. Anceps does best in pots, but Autumnalis requires a basket or a block. Both thrive well in moss and charcoal, and a fair supply of water, while growing, especially if they are on blocks. Both are winter-flowering plants, and require a good season of rest after they have flowered. Re-potting, basketing, or blocking should take place just before new roots are pushed in spring.

LYCASTE SKINNERI is a real gem for an amateur. There are many varieties, but all are good. Its main requirements are:—The cool end of an intermediate house or warm end of a cool one; moss and charcoal, with a little fibry peat; plenty of water while growing, and moderate dryness while at rest. Scale is apt to trouble it, but the use of the sponge will keep it under.

MESOSPINIDUM VULCANUM and sanguineum are two neat, free-growing plants which freely produce elegant spikes of sanguineous flower. Both are easily cultivated.

MILTONIAS are good, free-growing, free-flowering orchids. The cool end of the house, and a couple of inches of material to root in; steady moisture, and shade from sun, will secure success in their cultivation.—*Country Gentleman's Magazine.*

FORESTRY.

A PLEASING and useful custom has lately arisen in some of the duty American States of setting apart one day in the year to the of tree-planting. The 28th day of April was "arbor day" in the State of Michigan, and we understand that a very large number of trees were planted, and that much interest was shown in the occasion.

IF we could only induce the natives of this country to follow this good custom, great benefit might be conferred in the country.

IT would be advisable too, if Government would also aware prizes in money for such of these trees as had arrived at the age of three years, and were healthy and flourishing. These two customd introduced, the Forest Department might, so far as preservative work is concerned, be abolished.

THE Persian Government has lately taken into consideration the propriety of granting concessions for the exploitation of the forests of Ghilan and Mazanderan, and for working the mines. Divers promises have been made; but every body who understands Persia will know that those mean absolutely nothing. The only institution in Persia that have any pretensions to success are the regiments drilled by the Austrian officers under Colonel Schemer, the cavalry drilled as Cossacks under Colonel Domoutovitch; and, to some extent, also, Monteforte's police. Under an administrator like the Sipah Salar, those might flourish for the time, and even improve; but the moment European supervision ceases, the reforms will fade away.

TEA.

THE latest report we have from Ladak, contains good news for the tea planters of Upper India. For a considerable time Indian tea was not allowed to cross the frontier into Chinese Turkestan. We now learn that "A messenger from Yarkand, who reached Ladak on the 15th June with letters, reports that the prohibition on the import of Indian tea into Chinese Turkestan has been cancelled. A Ladak trader who received letters by the same man, confirms the report. A notice, it appears, has been issued at Kilian, that Indian tea may be allowed to pass in without hindrance, and that duty would be levied on it at Yarkand. The price of Indian tea in the Yarkand market is now nearly four times that current in Kangra." This should open up an entirely new market for the Kangra planters, and those of Upper India generally. The principal demand in the direction of Turkestan is for brick tea, and its manufacture is very simple, and will be amply repaid by the high prices ruling. The cause of these high prices is, of course, the great distance the tea has to be carried, and the difficulties in the way of carrying on the trade across the Himalayan passes. These are high, as much so as 17,000 feet above sea level, although the general height is from 10,000 to 14,000 feet. The roads are very bad, and at the best are but bridle paths. Once the foot of the hills is reached, goods are transferred from the back of bullocks, mules, &c., and are carried over the mountains by goats and

sheep. These little animals carry about 25 lbs. each, and take about three months to cross the hills. This is one of those routes on which a wire tram would be useful and cheap, and we commend the idea to those enterprising gentlemen who are always casting about for some scheme on which to base a prospectus!

At "Ye Old English Fayre," recently held at the Royal Albert Hall, an opportunity was presented of introducing fine Indian teas to the notice of the public, which was promptly seized by the Indian Teas Districts Association. A box of fine Darjeeling tea was given for the occasion. The refreshment stall, presided over by the Countess Cadogan, was decorated with photographs of Indian tea gardens, and illustrations at the process of manufacture. Cups of Indian tea were sold at one shilling each, and brought in a good sum to the charity, at the same time spreading the knowledge of, and stimulating inquiry for, the teas of the Indian Empire.'

THE TEA TRADE.

THE solidity and caution of the British character have passed into a proverb. The volatile Frenchman is supposed to go into matters of the greatest moment that may be fraught with the most serious consequences with a light heart; but such levity has never been attributed to the average Briton. He is supposed to take even his pleasures sadly; much more is he certain to be grave in his business relations, and to enter upon no operations even of lesser importance without long and careful consideration. "Lightly come, lightly go," is one of the proverbs which are supposed to decorate the walls of his counting-house; and the endurance and persistency of British trade, which still holds its own all over the world, are commonly attributed to the forethought and caution with which it has been established and promoted. The British merchant does not begin to build a tower without counting the cost, and from this it results that the towers of his trade are completed and stand against all the assaults of nature and of his competitors.

It is difficult, therefore, to understand how it is that the China tea trade is such a notable exception to the general rules of British commerce. To judge by acknowledged results, it is impossible to believe that any such caution as is supposed to govern British commercial operations generally, is employed in Hankow and Foochow at the opening of the season's business at these two great ports. To begin with, uncertainty is surely an element to be avoided if possible; but the supply and demand of tea are as uncertain as anything in which there is some regularity, can be. It is fairly certain that in nine years out of ten more tea is available than the Home markets can take. Year after year the Home circulars reiterate that all chance of profit has been lost by the oppression of excessive supplies. The result is a greater competition in London to sell than to buy, and prices are fixed by the generosity of the buyers instead of by the firmness of the holders. If the Chinese mind could be got to realise the importance of accuracy in the statement of facts and the collection of statistics, the way of the tea-buyer would be a little more plain. As it is, there are two important elements that we can never ascertain. How much leaf is available for export in a given season and what is the actual cost of bringing this leaf to market are matters merely of rumour, and as the relaters of these rumours are too much interested, except in very rare cases, in falsifying them, reliance on them is indeed leaning on a bruised reed. Allowing for the fluctuations resulting from occasional disturbing causes, consumers must pay for an article on the average something over the actual cost of production; and in that excess lies the profit to those engaged in its distribution. If then we could learn with certainty the actual cost of growing, picking, preparing, packing, and transporting to Hankow a chest of tea, we should have one of the necessary elements to the conduct of a successful trade. But until the country is opened up, and it is possible for the merchant or his agents to travel freely in the interior and make the necessary investigations on the spot, this knowledge is unattainable. The same facilities are necessary to enable us to arrive at a knowledge of the amount of leaf available for export in a given season. In India there are statistics gathered by the Government, giving the area of ground devoted to tea-growing, the approximate amount of capital employed, and the age of the gardens, with the average yield of every acre. And a man who buys tea on the market in Calcutta, can do it intelligently and with a fair prospect of success if he uses ordinary caution. But all this is impossible in China. Our knowledge of supply is derived from the vague and unreliable reports of the Chinese brokers, whose object it is to under-estimate the production, and increase competition accordingly. We can only collate and criticise their statements that the weather has been very unfavourable; that there has been too much or too little rain or snow; that the middle-men lost so much money in the previous year; that their operations will be largely restricted by want of funds; that the Chinese bankers with whose money so much of the first crop is moved, are indisposed to make the usual advances, &c., &c.; and by and by we find that the irrepressible tea plant has overcome all those drawbacks, and that the market is as full of musters as ever. At last, however truthful the brokers may have appeared to be when they were telling these melancholy tales, there are always ten thousand packages more available, if a buyer can be found. But worse remains behind. The foreign buyer has no control over the quality of the crop, for he has to buy it exactly as it comes to market ready for shipment. This was of comparatively little importance when China was the only tea-producing country. The best tea then meant the best of the year, for one crop of tea was compared with another of the same country and the same season. But India is now furnishing a standard against which China has to measure herself. India, where the production of tea grows so fast that the export this year is expected to reach sixty million pounds; and where a new soil and foreign control produce strength and quality, surpassing, except in rare instances, the best that China can afford. We can no longer send forward safely the whole China crop, and allow India to supplement its deficiencies. The Home consumer is now taking the whole of the Indian crop, and turning to China to fill up the void left by India.

Considerations such as these ought to temper the ardour of the buyers who have flocked as usual in the last fortnight to Hankow. For unless they have due weight, nothing but loss can be expected. To be safe, China ought to export this season to Great Britain, some thirty to forty million pounds less than last year. This will not be the case unless a catastrophe occurs; a catastrophe that must occur sooner or later, if these warnings are not attended to. If there is the usual hurry to buy tea this week in Hankow, if the first crop brings remunerative prices to the tea-men, a large yield is certain. When the tea reaches here in the autumn, it must be sold, for it is of no other use to the Chinese. When it gets to London it must be sold, for no one there will take the risk of holding so perishable an article. We are not sanguine that the caution which characterises other branches of commerce will be employed this year in Hankow; for it is a far cry from London to Hankow, and there is no race of men so hopeful as are chaseers at the commencement of the season.—*N. C.* *Herald.*

THE MYSTERY OF THE CHINA TEA TRADE.

WE do not think it necessary to make any apology to our readers for directing their attention to the letter which appears on another page under the signature of "Chaa Szee." Most of the residents here have such a direct interest in the matter he treats on that, we think it well to make a few remarks on what appears to us a very important subject. Our correspondent states, and apparently it would be difficult to deny it, that shippers of tea are paying in Hankow from 6*d.* to 7*d.* per pound over rates current recently in London. The question then to be solved is,—are there any reasons sufficiently good to warrant such an advance? One answer to this would be—and there is probably some reason in it—that the sale he refers to was not a fair indication of the value of the tea; that the tea was, in fact sacrificed. We have taken some little trouble to find out whether such might not have been the case, and the conclusion we have arrived at is that the tea in question would probably have fetched from 1*s.* 3*d.* to 1*s.* 4*d.* instead of 1*s.* 1*d.*, had it been more carefully handled on arrival in London. This then will apparently do away at once with half the discrepancy which he asserts to exist, but it must not be forgotten that this is a risk which a large proportion of shipments must always run. It also appears that his sale is a fairly recent one, for he states that he purchased the tea in December; it could not, therefore, be on the London market before the latter end of February, when we are informed that teas of good quality were scarce and wanted, a state of things which will not exist when present purchases arrive. It is, therefore, a fair argument that the value of such tea will be less when the deficiency ceases. For the sake of argument, however, we will assume that the present value of such tea in London is 1*s.* 3*d.* per lb. Is there any just reason why 1*s* 8*d.* should be paid for similar, or, according to our correspondent, for inferior quality? To our minds one fact only would justify such an advance, and that is the certainty of a marked deficiency in supplies. Reports from Hankow refer to a deficiency in the first crop of from 10 to 15 per cent. Without going so far as to deny that this may be possible, we must confess to being somewhat sceptical on this point, nor do we thing that a short first crop necessarily means a short total export. The season 1878 and 1879 is, we doubt not, still within the recollection of many of our readers, and if we are not mistaken there was a very large actual decrease in the first crop. Still the total supply of the season was ample, or, judging from the disastrous results, more than ample, that season being acknowledged as one of the worst the trade ever experienced. We are therefore unable to see that a problematical deficiency is a sufficiently good reason for paying in China 5*d* per lb. more than teas are worth in London.

But are buyers in London, at the time present shipments arrive, likely to act upon the supposition that there is a short supply, or will they treat the statement as nothing more than a report? The cry of "Wolf" has been so often raised and so often proved to be devoid of truth that we have no hesitation in stating that not the slightest heed will be paid to this report until an actual deficiency will be apparent. Judging from the fact that they will carry over from last season a large surplus stock; that the supply from the south of China promises to be large; that, as our correspondent observes, there is the certainty of a large increase from India, we can see no chance of any deficiency being felt in London for many months to come. Granted that the whole Chinese crop is inferior in quality, we should—it may be in our ignorance—have supposed that this was a strong reason for paying less than usual, whereas that the contrary as the case seems a tolerably well authenticated fact. That there will most certainly be a dearth of fine teas of China growth seems inevitable, and those shippers who, taking this into consideration, have only paid enhanced prices for fine teas, may probably find that they were justified in doing so, but because the whole crop proves to be inferior, appears to us to be a very poor reason for raising the price all round, or at least for qualities such as our correspondent mentions. Taking a calm unbiassed view of the whole matter, we can form no other conclusion than that shippers are running enormous risks, which circumstances, at any rate at present, do not justify. As soon as the inferiority of the China crop will be known in London, the inevitable result, to our mind, will be to considerably enhance the value of Indian teas and to the same extent depreciate the value of China teas. The public at Home is, by this time so accustomed to obtain tea of really good quality for 1*s.* 8*d.* per lb., that they will not be easily satisfied with anything inferior. This tea is made up of a judicious mixture of Indian and China, and to make up for the deficiencies of the latter more Indian will be used and less money paid for the China.—*N. China Herald.*

COFFEE.

COFFEE LEAF-DISEASE.

MR. SCHROTTKY'S SEVEN MONTHS' CAMPAIGN.

To the Chairman and Members of the Planters' Association of Ceylon.

Sirs,—When in November last, while on a touristical visit to Ceylon, I decided to make use of a month's leisure, to institute with the help of some practical planters a series of experiments with the view to determine whether it was really beyond the reach of Chemistry to give coffee planters a remedy or palliative of coffee leaf-disease (this most dire infection) I had no idea that the work would occupy seven months.

I came very early to the conclusion that science in this case would not be so helpless, as she is generally represented to be, and that the disease (being fairly accessible) could not only be topically destroyed by a number of chemicals, but that the conditions of the sap of the tree could be artificially so altered as to make it less favourable to the development of the disease in the leaf cells. But to reduce this conclusion into a practical form, to devise a practical and cheap method of using any of these chemicals as topical applications or otherwise, and after having found a method, to obtain such proof of the results of the same as would be readily understood and acknowleged by practical men:—this I have found an arduous task which I more than once despaired of bringing to a satisfactory conclusion,

and which has occupied a time that I have only been able to give to it by greatly neglecting and sacrificing my interests elsewhere.

With some professional repute engaged, I was naturally reluctant to leave such an important work half done, and with its practical issues involved in doubt, it is therefore with more than ordinary pleasure, that I proceed now to sum up the results these experiments have yielded up to date, and which I think warrant some very satisfactory conclusions regarding the method I recommended for the mitigation, if not prevention of leaf disease, *viz* vaporisation with carbolic acid.

Having a practical object in view, I have investigated the whole subject (as far as I was able, having only a general and not a special knowledge of mycology) mainly from a practical point of view, and desiring to make this paper as short and concise as possible, it will, I hope, be understood that my main conclusions though stated in a few words have not been arrived at without full consideration of every fact that I have been able to observe myself, or been able to collect from such of the planters whom it has been my privilege to meet in my seven months' study of the subject.

THE FUNGUS.

As described generally by mycologists, and more specially by Mr. Marshall Ward, what is known as coffee leaf-disease is a parasitic fungus (*Hemileia vastatrix*) propagated by spores, whose germinal tubes when in contact with the lower surface of living coffee leaf, enter into its stomata, establish themselves in the intercelular tissue, develops at the expense of the cell sap into mycelium which finally forms a receptacle (the Uredo) from which arrives and break through the epidermis of the leaf kidney-shaped orange-coloured Uredo-spores, forming clusters of what constitutes the well-known rust. The same mycelium also produces a secondary spore, the Teleuto-spore.

Before fruiting the presence of the fungus or rather of its mycelium in the leaf tissue, is evidenced by pale yellow circular spots (called pinspots) transparent or opaque. The healthier the disease, the more opaque the spot.

The fungus has been clasified (by Berkeley and Broom I think) as belonging to the Uredineæ. Any doubt as to whether this classification is correct has been removed by Mr. Ward finding the Teleuto-spore.

It is, therefore, perfectly reasonable to look forward to Mr. Ward (the mycologist specially engaged in Ceylon in the investigation of the different forms of this fungus) describing to us, before he closes his work, the three different cycles of 'generations of this fungus, and the other hostplant on which the transition takes place, this being a distinguishing feature of the Uredineæ.

But what makes this disease so formidable an enemy is the peculiar capability of the Uredo-spores (or rust) to produce themselves indefinitely by their constant germination and reproduction without the necessity of passing through the cycle of generations. These orange-spores, of a heavy oily character, germinate in contact with moisture (dew, rain, &c.) and their contents pass into a germinal tube. The spore becomes an almost empty cell, and the whole fabric is then extremely light and capable of wide diffusion.

Wind is, in my opinion, the chief cause of the dissemination of the spores before, but far more so (on account of their lightness) after germination from one disease spot to another, from one leaf to another, from one tree to another, from one field to another.

As far as I have observed, and from information I have collected, the leaf-disease fungus spreads, during the periods favourable to the germination of its spores and to their establishment in the leaf from chronically diseased centres and travels in the direction of wind currents.

The idea that an estate is absolutely free from disease for, say, three months, and that then it appears simultaneously all over the estate, has, I think, its origin in untrained and defective observation, and is greatly due to the extraordinary rapidity with which the disease spreads when all circumstances are favourable.

The germinated Uredo spore will not establish itself in an incongenial nidus. Where congenial conditions do not exist, it will, even when over a stoma, simply dry up.

We may take it for granted that, considering comparatively, force and direction of wind and neighbourhood to diseased parts of an estate, each square inch of lower leaf surface of a coffee estate will receive an almost equal number of spores that maintain adherence. But on different trees the disease establishes itself in a different (but for the same tree rarely varying) force. There exists, therefore a condition of the coffee tree, or more properly speaking, a condition of the sap of the leaf cells which is peculiarly favourable to the development of the disease. In some trees, this condition is continually present, and on these the disease can nearly always be found; it is there in a constant and chronic form. In the generality of trees however, this condition occurs only twice a year, and it is during those two periods that the disease spreads itself from a few confined disease patches more or less all over the estate.

In the majority of districts these two general attacks of the disease cay be distinguished into a south-west and north-east monsoon attack, and then coincide closely, but generally precede by a little the natural, so to speak autumnal fall of the coffee leaf which takes place to a more than usually appreciable extent twice a year. In many cases only one such fall will be acknowledged.

These are periods, comparatively speaking, of a minimum of activity, of a minimum or alkalinity of the sap of the tree—periods when the trees are preparing their gathered stores of nutritious material for a new flush of leaves, when the cellular starch deposits are either changing or on the the point of changing into glucose, in order to enable its passage from one cell to the other for the formation of cellulose at the apical or axillary buds.

It is the period just before a maximum activity of the tree, during which the condition of the sap of the leaf cells appears to be most favourable to the penetration of the germinated Uredo-spore into the stomata of the coffee leaf and to its establishment in the intercellular tissue. The germinal tubes of this fungus share, no doubt, the apparent property of other absorptive vegetable forms, *viz*, that of an instinctive knowledge of the presence of congenial food. The condition of the sap of the coffee tree most congenial to the establishment of the fungus is, I take it, when the cellular starch deposit, the leaf are in a state of transition into glucose or sugar, which substance, I am greatly of opinion, furnishes the chief food of the fungus. And this transition, be it well borne in mind, can only take place in the presence of a free acid. The sap of weakly trees seems to be always in that condition.

It remains only to be said that while I agree with others in considering the chief damage done by the disease due to the premature fall of leaf, I would add to this, that I feel assured that the disease has a reactionary influence; that it leaves behind in the tree, after a severe attack, a subtle poison, causing a subtle disposition in the tree to recreate the condition avourable to its re-development, which interferes with and is antagonistic to the natural disposition of the tree to form stores of insoluble starch deposits. From these starch deposits, fruit in the first instance is formed. The fungus requires its food in a soluble form and after a series of attacks the trees appear to readily furnish it. Combine this with the premature fall of leaf, and short crops and the non-setting of blossom can be easily accounted for.

EXPERIMENTS.

WITH PROBABLE REMEDIES FOR THE DISEASE.

My experiments were directed, 1st, to ascertain whether the condition of the tree by assimilation of any chemical could be rendered less susceptible to the disease, and 2nd whether a practical method of topical application of some chemical or other, could not be devised that would act better than the sulphur and lime treatment, and which would not result, as the latter seems to have done in the majority of the cases, in leaving the trees, for some considerable time afterwards, in a more susceptible state as regards the disease than if they had never been treated.

1st SET OF EXPERIMENTS.

To eliminate all chance of error and of mistaking cause and effect in these experiments, I decided to introduce the chemicals direct into the cambium of the stem by a system of lateral absorption which I called inoculation. Doubt was expressed at the time as to whether absorption through the cambium could take place. This matter has finally been set at rest; for experiments made by me at Holbrook estate with cinchona trees, showed that trees of about 150 lbs. weight each, exclusive of roots were capable of absorbing through the cambium in 7½ days up to 6 lbs. of different chemical liquids, the non-assimilated portion of the chemicals accumulating in the leaf cells until (only however in some cases) total collapse of the same ensued.

These inoculation experiments have been detailed by me in a paper written at Doteloya and published in January, and need not be republished. My general conclusions are:—chlorides, nitrates, bi-sulphates, superphosphates, and all acids and sour organic manures are apt to increase the susceptibility of the tree to the disease. Sulphates, phosphates, or generally speaking neutral salts that can combine with another atomic weight of acid, all alkalies and antiseptic chemicals (other than chlorides and such as do not owe their antiseptic character exclusively to their oxidising or deoxidising power) decrease the susceptibility of the tree to fall a victim to the disease. Pre-eminently successful among the latter I found carbonate of potash and carbolic acid. When absorbed into the system of the tree while the fungus was healthily established in the leaf tissue, either of these chemicals prevented the fructification of the pinspots, in some cases entirely; in no case more than 22 per cent. of them fruited, while on adjoining untreated coffee, under exactly similar conditions and during the same period, from 76 to 100 per cent. of the observed pinspots had fruited.

Carbolic acid was the chemical I experimented with almost conclusively, after the preliminary experiments were over, as it had given me even more satisfactory results than the carbonate of potash.

It was applied to the stem of the tree mixed into a paste with fine soil and water in about 5 per cent. strength, a slip of stout paper being tied round the tree in the shape of a cup to hold the paste.

The chemical penetrated in sufficient strength into the cambium cells to cause their collapse for some distance inwards, but the strength and causticity of the chemical decreased of course until weakned enough to effect entrance into the living cell without causing collapse. Traces thereof (in a combined form of course) were bound to exert their influence on the leaf cells.

One of the chief properties of carbolic acid is its capability of arresting organic change or decay, this power being appreciably asserted in its most dilute form. The fungus, according to my conclusions, luxuriates in cellular tissue, contents of which are in a transient stage. The faintest trace of carbolic acid will arrest this, will stop for some time the conversion of the starch deposits into sugar; that is to say, will prevent the formation of what constitutes, in my opinion, the chief food of the fungus—the result will, of course, be that the mycelium, if still young, will die without fructification for want of suitable food. And this has virtually been the practical result of the above treatment. But the effect of the carbolic acid thus used is of an evanescent character, and I came, somewhat reluctantly, to the conclusion that for this method to be of any pratical value, considering the wide and universal prevalance of the different forms of the fungus, it would have to be supplemented by topical application calculated to destroy these forms.

This led to reconsideration of the results of the second set of of experiments, ending in my being able to combine the essential features of both.

The inoculation process involved some danger to the trees for in some cases the carbolic acid penetrated in sufficient strength to collapse all the cambium cells; but this danger could have been easily eliminated by weakening the strength of the application.

2ND SET OF EXPERIMENTS.

Instituted to determine with what success the fungus, in its more or less developed state, could be destroyed by external applications, choosing such substances and chemicals as were known to be inimical to fungoid life.

Out of the many substances tried sulphate of iron and copper, arsenical solutions, acids, potash, &c, &c., two chemicals were found in our preliminary experiment at Doteloya, to have an eminently decided effect both on the fully developed orange spores of the *hemileia* and on the yet unfruited *mycelium*, which both it killed *without* injuring the healthy tissue of the leaf. These two were sulphate of soda (10 per cent. solution) and carbolic acid (1½ per cent. solution).

Either chemical in those solution changed the orange-coloured spores into whitish looking bodies considerably shrunk, appearing under the microscope as white empty shells, the unfruited mycelium dried up and left a brown spot as far as its ramifications extended.

The observations were made under the microscope. Both these chemicals were tried on a practical scale by syringing their solutions through the foliage. The sulphate of soda application was practically a failure, not more than ten per cent. of the spots and spores being destroyed by it. The fungus seems to possess a power of refusing contact with it when applied as a spray, and this practical difficulty will probably occur with most saline solutions.

The application of carbolic acid gave more satisfactory results. Mr. James Blackett and Mr. Drummond, on close examination of the area a few days after the application, decided that from 40 to 60 per cent. of the diseased patches and spores of the fungus, on the trees had been destroyed without injuring the young shoots or leaves. But the practical difficulties of syringing a whole estate seemed insurmountable, and to quote from Mr. Blackett's appendix to my report on the results of these preliminary experiments: "*the external application of the solution of sulphate of soda or the diluted carbolic acid have too many drawbacks in my [Mr. Blackett's] opinion to make them at all practicable.*"

Mr. Blackett laid more weight on the results of the first set of experiments, and I put aside therefore all consideration to topical applications, until I came to the conclusion that the results of the inoculation process with carbolic acid were not sufficiently good to enable us to battle with the disease with any chance of success.

I then once more considered carefully the subject of external applications the practical difficulties of applying liquids &c., and finally decided to try carbolic acid absorbed into and used as dry powder in the same manner as sulphur and lime, as an external application. I used this powder, consisting mainly of finely slaked and sifted coral lime, a strength of about 3½ per cent. acid.

Though the carbolic acid is essentially an alcohol, it enters into a feeble combination with caustic lime, and forms what may, though somewhat incorrectly, be called a carbonate of lime.

On exposure to the atmosphere the carbonic acid thereof combines with the lime, sets the carbolic acid free, which thus escapes as vapour into the atmosphere.

Used in this way, the carbolic acid powder has given me such satisfactory results that I have had no reason yet to change either its strength or the mode of application. The treatment of a diseased area with this powder, cast broadly through the foliage of the trees results in stems, branches, leaves, and every square inch of ground being covered with an appreciable layer of the powder. The ground, stems and branches are covered most thoroughly, but a portion of the lower surface of the leaves seems to the naked eye always to have escaped somewhat the application, though under a magnifying glass, the fine, impalpable particles of the powder can even there be seen in multitudes.

The effect of the treatment on the disease is 1st, the destruction of spores and other forms of the fungus on the ground, 2nd, destruction of spores on fallen leaves, on the stem and branches, 3rd, destruction of spore patches on the foliage of the lower branches and the drying up and prevention of fructification of the pinspots on the same; and 4th, the *partial* destruction of spores and drying up of pinspots on the diseased foliage of the higher branches.

Bearing in mind the great importance that has been laid by Messrs. Abbay, Ward, and others, on the gathering and burning of the diseased leaves which only represent a small fraction of the spores that have been shed in any one area, the benefit derivable from a wholesale destruction of not only the spores on the fallen leaves, but also of those that have fallen on the ground and the majority of others distributed elsewhere in the treated area will, no doubt, be fully appreciated.

The treatment will have a maximum destructive effect on the different forms of this fungus on the ground, on the foliage of the lower branches in the absence of high winds and in coffee which covers the ground well, and when there are heavy dews or a slight shower *after* the application to supply the moisture necessary for contact. I have not yet finally decided whether heavy rain *immediately* after the application neutralizes the benefit. Heavy rain a day or two afterwards does not. Under favourable circumstances, pinspots and spores, even on the highest branches will be affected, by the vapour being retained within the area. It will, on the contrary, have a minimum destructive effect during high winds, on badly covered ground, open patchy, places on trees on bordering the upper side of road, &c.

The vapour of the carbolic acid in an area thus treated under average favourable circumstances is distinctly noticeable by its penetrating smell for about eight to ten days after application; and in addition to the destruction of countless numbers of spores on the ground and on the fallen leaves by the 3½ per cent. carbolic acid powder, there has been unmistakeable evidence collected that so long as the atmospheric air is tainted with the vapour of this most powerfully antiseptic chemical, the disease can make no progress. The carbolic and vapour is, of course, during this period breathed and absorbed into the system of the tree by the stomata of the leaf, and its effect of reducing the susceptibility of the tree to the disease is very much the same, and rests on the same basis as the effect of the inoculation process with the same chemical, and which already has been fully explained.

It will now be easily understood that if an estate is dosed in a proper manner, and at a proper time with this carbolic acid powder, it may be carried through the period of an attack with little appreciable damage.

I have since March last now treated over 600 acres of coffee with this method of vaporization; have also carefully, from time to time, examined what had been done in January last, as well as what of the large area had been done first, and have now finally come to the conclusion that by two applications costing Rs. 4 to Rs. 5 each per acre, used at a proper time and under average favourable circumstances, an estate can be carried through an attack of the disease with little damage, and that the diminishment of spores (when operations are carried on over a considerable area) and the general improvement in the tone of the trees which seems to follow the treatment will make the area less liable to suffer from the disease during the next favourable period for its development.

But still I would advise that four applications costing a total of Rs. 16 to Rs. 20 per acre, including everything, should be given during the first year. An expenditure of Rs. 8 to Rs. 10 or even less the second year should suffice. The preparation and application of the powder is extremely simple. The coolie understands it readily, and, though disagreeable work does not object to it; so that under average intelligent management I believe it perfectly feasible to battle successfully with leaf disease with the above reasonable expenditure.

The degree of success obtainable will depend on how and when the applications are given. Detailed instructions as to how and when this treatment should be applied will form the subject of another paper which I have under consideration, and which I hope to finish after another visit to the estates that I have treated before my departure to India.

The fungus will best be regarded in the light of a weed which has been allowed to over-run and firmly establish itself on an estate. It will involve some trouble and a good deal of expense in the first instance to try and keep it under, but in the natural course of things the damage done by it ought to be sensibly reduced at each periodical attack following the treatment I have recommended; and the cost of keeping it out of a certain area, when operations are carried on over an appreciable extent, will be after a year or eighteen months very trifling. For though the danger of infection from neighbouring untreated estates is considerable, the spores thus re-introduced into a treated area will amount only to a very small fraction of the countless millions of spores that are accumulated by unhindered growth and fruition of the fungus within a given area. It is almost needless, I think, for me to add that disappointment will result if any planter thinks he has only to scatter a handful of powder over one part of the estate, to see the disease disappear out of the other part. Here once the battle is earnestly begun, there are two qualities that will ensure success—PATIENCE and PERSEVERANCE.

The following records and reports of the observation of the different planters with whose assistance I carried on my experiments, and who tried and tested the treatment as finally recommended will, I trust, be accepted as independent testimony that my conclusions are based on data and results, that were apparent not only to the trained eyes of an experimentalist, but which were also apparent to the careful and intelligent observation of practical planters.

The cause and effect of the vaporisation treatment with carbolic acid on the incipient forms of the fungus when established in the tissue of the coffee leaf cells, and of reducing the susceptibility of the tree to the disease, I find exactly the same as in case of the inoculation process. The observation and results of the experiments made with the latter process may therefore be fairly accepted, as proof of the merits of the former in that respect, when operations are made under circumstances that admit of the vapor breathed and absorbed into the system of the tree.

To be continued.

CINCHONA.

DR. THISTLETON DYER brings to the notice of the India office a new variety of cinchona plant. He is not aware of its botanical name, but the bark is known in the London market as *China cupreæ*. It grows from 2,000 to 3,000 feet above sea level, and is at present confined to Central America.

WE hear that some cinchona blossom picked from the Emulina trees has been pronounced by Dr. Triemen to be of the true Ledgeriana type. This with the fine price realised for the bark at a recent sale should set at rest the question as to whether the variety is of this valuable kind or not, and should satisfy those who may have purchased seedlings from this estate that they have secured Ledgeriana plants and not a worthless hybrid.

PLANTS of the Cinchona Ledgeriana at Rs. 500 a thousand are bad enough, but the latest extravagant price paid for this variety is quoted at £36 per ounce for seed. The seed was taken from trees of a superior kind, of a good age, and the bark of which had been tested, ertising the seed is in Java.

VALUE OF CINCHONA TREES.

BY a strange coincidence, at the precise time when we were publishing the incredulous comments of our London correspondent on the valuation of cinchona trees by the Directors of a South India Limited Liability Company, we received from the proprietor of the Monerakande Estate, Haputale, an account of the yield and valuation of bark from a single *succirubra* tree on his fine property, which curiously enough shew results exactly coincident with the value assumed by the South India directorate in question.

The tree was not selected from amongst many, but taken at random; its age was nine years, and it was barked not rooted up, yielding 16 lbs. dry stem bark and 9 lbs. branch bark. Here we have a total yield of 25 lbs. of dried bark from one tree nine years old. The broker's valuation of this was, stem bark 5s. per lb., branch bark 3s. 7d. to 4s. 6d. per lb, and a few chips at 3s. 3d. to 3s. 6d. per lb, this valuation shews the excellent quality of the cinchona grown in the Haputale district. Monerakande estate has, we believe, an altitude ranging between 2,500 and 5 000 feet.

The analyses of these various products gave the following results:—

Stem bark, crystallized quinine sulphate	... 2·69	per cent.
Branch bark, crystallized cinchonidine	... 1·26	do.
Do. crystallized genuine sulphate ...	... 2·09	do.
Do. do. cinchonidine ...	... 1·80	do.
Do. do. cinchonine (alkaloid) ...	... 2·30	do.
Chips cinchonine (alkaloid) ...	... 4·00	do.
Do. crystallized genuine sulphate ...	... 1 47	do.
Do. do. cinchonidine	... 1·60	do.
Do. do. cinchonine alkaloid	... 2 20	do.

There may not be any very remarkable results to be found in these various analyses, but it is nevertheless a fact that the quantity of bark taken off brings the value of this one tree up to about £5. Of course, it would be very injudicious to base any large calculation on such returns, but the fact is indisputable.—*Ceylon Times.*

TOBACCO.

GROWTH OF TOBACCO IN IRELAND.

IN the House of Commons on Monday, Mr. Gladstone said, in reply to Sir Ea dley Wilmott, that there had been no recent discussion of the question with regard to the growing of tobacco in Ireland. If that question should arise, undoubtedly, it would be with reference to the kingdom at large. The hon. member was perhaps aware that for a period of fifty years the growth of tobacco was permitted in Ireland, and that the growth of it was also protected by differential duties. He might also know that the withdrawal of that permission was recommended by a Committee in 1830, inasmuch as the experiment had not been successful. At the same time, he regarded the prohibition of the growth of any agricultural product by law as a thing very unsatisfactory—(hear, hear)—and consequently he was at all times very open to the reception of any statement or suggestion tending to show that if that prohibition were removed, they might satisfactorily levy a duty on that commodity when grown at home as on that wh [illegible] was bro [illegible] into the country.

STATISTICS.

THE earnings of the Eastern Bengal Railway for the first nine days of July 1881, were Rs. 74,978, or Rs. 436-8-10 per mile, as compared with Rs. 87,957, and Rs. 512-1-11 respectively for the first ten days of July 1880. The mileage in both years was 171½.

THE earnings of Indian Railways for the week ending 9th July were as follows per mile :—

B., B. and C. I. Railway	...	209	5	1
Madras do.	...	136	8	7
For nine days ending 9th July :—				
G. I. P. Railway ...	...	377	1	2
E. B. do. ...	...	436	8	10
H. & N. S. do. ...	...	133	7	4
E. I. do. ...	...	632	2	11
O. and R. do. ...	...	162	15	6
For 12 days ending 30th June :—				
R. S. Railway ...	...	299	7	10

THE following are the earnings of the Indian Railways per mile, for the periods referred to :—

G. I. P. Railway	5 days ending	30 June	802	8	9
H. N. S. do.	5 „	30 June	121	6	9
O. & R. do.	6 „	30 June	104	1	7
E. B. do.	12 „	30 June	684	0	11
E. I do.	12 „	30 June	950	11	1
B. B & C. I. do.	week ending	2 July	821	2	4
Madras do.	„	2 July	168	9	11

THE earnings of the Eastern Bengal Railway for the week ending 16th July, was Rs. 84,662, or per mile Rs. 492-15-0, as compared with Rs. 77,457 and Rs. 450-15-10 for the corresponding week of last year. From 1st to 16th July 1881 and 1880, the earnings were Rs. 1,59,640 and Rs. 1,65,414 respectively.

THE earnings of the East Indian Railway for the week ending 16th July were Rs. 7,07-915-4-3 as against Rs. 6,35,479-10-4 for the corresponding period of 1880, or Rs. 470-9-9 and Rs. 421-9-10 per mile respectively. From 1st to 16th July 1881 and 1880, the earnings were Rs. 16,58,876-3 3 and Rs. 15,13,165-15-8 respectively.

THE following is the population of Calcutta, as ascertained by the recent Census ;—

Wards.	1876.	1881.
Shampooker	24,531	25,487
Koomartolly	32,482	25,682
Burtollah	25,167	25,527
Sookea's-street	20,115	20,572
Jorabagan	37,305	36,318
Jorasanko	34,395	32,824
Burra Bazaar	22,438	20,769
Colootolla	48,502	47,323
Moochepara	37,427	39,241
Bow Bazaar	22,476	21,627
Puddopooker	19,557	20,516
Waterloo-street	5,445	5,785
Fenwick Bazaar	25,573	26,051
Toltollah	25,883	26,063
Collingah	12,194	11,840
Park-street	4,358	4,968
Bamun Bustee	6,269	6,125
Hastings	4,919	4,953
Town Proper	409,036	401,671
Fort William	2,803	3,348
Port of Calcutta	17,696	28,200
Total for Town	429,535 (1872)	433,219 (1881)
Total for Suburbs	257,149	251,439
Calcutta and Suburbs	686,684	684,658

MR. GRENFELL, in his article "What is a Pound ?" In the *Nineteenth Century* for this month, says that the amount of the precious metals in use for other purposes than circulation is too small to have any influence on their value. The opinion of the Governor of the Bank of England should carry some weight, but when it is considered that gold and silver are very fairly durable, and do not waste rapidly from use ; and when the quantity of each produced during about the last 400 years is also considered, it is not easy to understand how the passing of these metals from hand to hand in the course of trade could have absorbed so much as has practically disappeared from circulation. From 1493 to 1875 the quantity of silver produced reached 397,125,267lbs. Avoirdupois, which at 4*s.* 6*d.* per oz., gives a value of £1,429,650,961. From 1876 to 1880 the total production of silver is estimated at 76,900,000lbs. weight, of an estimated value of £21,786,250. The production of gold from 1493 to 1875 reached in weight, 20,797,359lbs. Avoirdupois, worth at £4 per oz., £1,331,030,976 ; and from 1876 to 1880, 1,663,000lbs. Avoirdupois, value £106, 600,000. Of the silver produced from 1493 to 1875, £167,651,880 came from Mexico, £68,688,400 from Peru, and £82,978,720 from Potosi (Bolivia). From 1876 to 1880 the production of the United States was £39,900,000, as compared with Mexico £27,000,000. "Other countries" produced a total estimated at £10,000,000. The proportion of gold to silver was 1 per cent. from 1493 to 1520. It then sank gradually from 7 in 1521—44 to 2 from 1560 to 1660. From 1661 to 1840 it fluctuated from 4 to 2. In 1841-50 it rose to 7. From 1851-55 it was 18 ; 1856-60 19 ; 1861-65,4 ; 1866-70, 13 ; 1871-80, 8. Of the whole supply of gold, three-fifths has been produced in the last forty years.

Plants of the Cinchona Ledgeriana at Rs. 500 a thousand are bad enough, but the latest extravagant price paid for this variety is quoted at £036 per ounce for seed. The seed was taken from trees of a superior kind, of a good age, and the bark of which had been tested, and the firm advertising the seed is in Java.

AUSTRALIA and New Zealand are but young countries. A few years ago no people inhabited them save a few scattered aborigines and those vast island were practically uninhabited for all the good effected by those living in them.

The following will shew what is being done in one industry alone, and this list, be it remembered, only includes a few of the leading cattle owners in the districts of New Zealand:—The following return of sheep held by (squatters) taken from the *Government Gazette* for Canterbury and Otago, New Zealand gives an idea of the vast flocks owned by single farmers in the Australasian Colonies :—New Zealand and Australian Land Company, 300,000 sheep ; Mr. Robert Campbell, 386,000 ; Mr. George Henry Moore, 90,000 ; Messrs. Dalgetty & Co., 208,000 ; Messrs. Clifford and Weld, 80,000 : Sir Dillon Bell, 82,000 ; Hon'ble William Robinson, 68,000 ; Sir Cracroft Wilson, 48,000 ; Mr. Kitchen, 80,000 ; Mr. Allan McLean, 50,000.

THE United States Post Office Department has issued a statement of the results of an inquiry as to the amount and distribution of the postal business of the country during the year ending December 31, 1880.

The whole number of letters posted was	1,053,252,876
„ „ „ post-cards „	324,556,440
„ „ „ newspapers „	812,032,000
„ „ „ magazines and other periodicals	40,148,792
The whole number of packages of merchandise	21,515,832
Various	468,728,312
Total	2,720,234,252

The number of letters posted average twenty-one for each man, woman, and child in the United States. This total is then analysed, and the relative numbers of each State given in a table. The two extremes are, Alaska, with its unlettered population, and the district of Columbia, the centre of the postal system, and the seat of National Government. In Alaska, only one inhabitant in five is credited with one letter a year, while in the district of Columbia there are 85 letters posted for each inhabitant. The most letters are written where there is proportionally the largest intelligent adult population who are away from home namely, the newer States and territories. Colorado heads the list of letter-writing communities, with fifty-five and a fraction to each inhabitant. The settlers in Arizona write 32 letters each a year, Dakota 30, Montana 40, Nevada 32, California 26, Idaho 25, and Wyoming 42. The States, which supply most of the letter-writers of the territories, in addition to being the great seats of manufactures and commerce, come next, New York with 42 letters to each inhabitant, Massachusetts with 39, Connecticut with 33. The people of the South are not letter-writers generally, nor are they as much given to migration as the people of the North. The result is that the contributions of the Southern States to the mail bags are extremely small. The annual average for each inhabitant of Alabama is 7, Arkansas 8, Georgia 9, Kentucky 9, Missippi 6, North Carolina 6, South Carolina 7, Tennessee 7, West Virginia 8. The figures for other Southern States are, it will be seen, somewhat higher :—Florida 11, Virginia 11, Texas 12, Louisiana 15, New Mexico 13. The more Northern States which write the fewest letters are Delaware 16, Indiana 13, Wisconsin 17, and Washington Territory 15.

We publish the following papers at this Office :—

THE INDIAN AGRICULTURIST.

(MONTHLY.)

Rates of Subscription, including postage.

STRICTLY IN ADVANCE.

For India	Yearly	... ...	Rs. 12 0
	Half-yearly	... ...	„ 7 0
For Europe	Yearly	... ...	„ 13 8
	Half-yearly	... ...	„ 7 8

Single copies, Re. 1, back copies, Rs. 2.

Advertisements for the " Indian Agriculturist " should be sent in not later than the 23rd, to appear on the 1st of the following month.

Advertisements for the " Statesman " should be sent in not later than 5 p.m., to appear on the following morning.

INTENDING Subscribers will please forward their names and Subscriptions to the Manager, STATESMAN AND FRIEND OF INDIA, *Calcutta, to whom all business communications, in connection with any of the above papers, should be addressed.*

Advertisement Rates for any of the above papers.

1st Insertion 4 annas per line.
2nd „ 3 „ „
3rd and each succeeding insertion 2 annas per line.

The lines are calculated upon the standard length of the column. Contract rates will be furnished on application to the Manager.

SUBSCRIBERS would much oblige us, when remitting money for Subscriptions, &c., if they would clearly state for which paper it is intended, as great confusion arises from their omitting to do so.

Agents in London for the above paper :

GEORGE STREET, Esq. ..	*Cornhill.*
F. ALGAR, Esq. ..	*11 & 12, Clement's-lane, London, E.C.*
BATES HENDY & CO. ..	*4, Old Jewry, London, E.C.*

C. E. COLLINGS,
Manager.

THE AGRA BANK LIMITED,

Capital £1,000,000

Reserve Fund £150,000

CALCUTTA BRANCH.

CURRENT ACCOUNTS are kept, and Interest allowed, when the Credit Balance does not fall below Rs. 1,000.

DEPOSITS received available at any time, for Remittance to England in the Bank's Bills, and interest allowed thereon at the rate of 4 per cent. per annum.

DEPOSITS are also received for fixed periods on terms which may be learnt on application.

DRAFTS granted at the exchange of the day on London, Scotland, Ireland, and the Bank's Agencies in the East.

CIRCULAR NOTES issued, negotiable in the principal places in Europe.

GOVERNMENT and other STOCKS, and SHARES bought and sold and the safe custody of the same undertaken.

INTEREST, PAY, and PENSIONS collected; and every other description of Banking Business and Money Agency transacted.

All Remittances should be made payable to the Agra Bank Limited.

THE

WEEKLY CEYLON OBSERVER.

THE best newspaper publication in the world for tropical planting intelligence and all matters affecting the statistics of production and the practical cultivation of coffee, cinchona, tea, cocoanuts, cinnamon, cacao, and other similar products. The proprietors and editors (Messrs. Ferguson) have had prolonged experience in Ceylon, as journalists, and in connection with planting. The paper is largely circulated in Ceylon, India, British Colonies, and the United Kingdom, also in Java and Brazil.

Subscription, including postage 18 rupees (£1 16s.) per annum in advance, and Advertisements at 9*d*. per line of 10 words.

Also published (annually) by Messrs. Ferguson, at their "Observer" Office, the "Ceylon Directory and Hand-book of Information," on subjects affecting tropical cultivation as well as all Ceylon matters—1,000 to 1,200 pages demy octavo, price, 8 rupees (16*s*.) per copy, including postage; Advertisements, Rs. 20 (£2) per page, or Rs. 12½ (£1 5*s*.) half page. Orders (with Bank Drafts) for all the above received at the " Observer " Office, Colombo, Ceylon; or through Messrs. Geo. Street & Co., 30, Cornhill, London, and Messrs. J. Haddon & Co., 3, Bouverie-street, Fleet-street, London.

INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL VI.] CALCUTTA :—THURSDAY, 1st SEPTEMBER 1881. [No. 9.

NOTICE.

SUBSCRIBERS to the STATESMAN, FRIEND OF INDIA, *and* INDIAN AGRICULTURIST *are informed that arrangements have now been made by which these journals will for the future be published under the general superintendence of the undersigned.*

All communications regarding literary matter should be addressed to the Editor of the paper for which it is intended.

All communications concerning the general business of the STATESMAN AND FRIEND OF INDIA *Office, Advertisements, and Subscriptions to the* daily STATESMAN AND FRIEND OF INDIA, weekly FRIEND OF INDIA AND STATESMAN, *and* INDIAN AGRICULTURIST, *should be addressed to the MANAGER,*

WILLIAM RIACH.

13th June 1881.

CONTENTS :

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

ACKNOWLEDGMENTS.

TROPICAL AGRICULTURIST. No. 1, Colombo : *Ceylon Observer* Office, 1881.

CORRESPONDENCE.

WHEAT.

TO THE EDITOR.

SIR,—I am thinking of doing a little experimental wheat-growing, can you tell me

1st.—The average breadth of the rows, when wheat is sown by drilling ;

2ndly.—The average breadth of the intervening fallow intervals ;

3rdly.—How to make use of some substitute for a drilling machine, or how to drill without a machine ? Answers would oblige.

F.

10th August 1881.

TEA AGENCIES.

TO THE EDITOR.

SIR,—The high charges made by agents of tea gardens have been more than once noticed in the papers, but there is another point connected with these agencies, which, as far as I am aware, has not been brought to public notice. I refer to the fact that agents as a rule refuse to furnish regular weekly reports to the proprietors. As the proprietor is the person most interested in the condition and the prospects of the garden, in which probably the whole of his life's earnings are invested, it is but proper he should get such reports, and yet, as a proprietor informs me, such is not the case. There would be some excuse for such a procedure if it entailed any great trouble, but surely the reports which the manager sends to the agents could be copied without much trouble in the office of the agents.

PLANTER.

THE FARMERS OF INDIA.

(*To the Editor of the Pioneer.*)

SIR,—The writer of an able article under the above heading, in your issue of 11th instant, remarks that the *tuccavi* rules are a dead letter, and that neither Government nor the zemindar move hand or foot in the matter. I am not concerned now to discuss how far the intricacy of the *tuccavi* rules has led to this result. But at the same time it may be well to remove the current misconception that to pour advances over the country would be a sovereign remedy for the difficulties in which the ryot is involved. This would be very well if we were dealing with a *tabula rasa.* If we were starting a body of cultivators in a freshly reclaimed tract, it would undoubtedly be expedient to give them advances at an easy rate. But this is not the case in a long-settled country. Here nearly every cultivator has a standing account with his bunniah. He makes over to his banker the bulk of his produce, and draws on him for money as he wants it. This, no doubt, is a fatal arrangement for the ryot ; but it is so deeply rooted in the customs of the country that it is hopeless at present to abolish it. With a cultivator in this position the well-meaning attempt of a paternal Government or zemindar to assist him, only lands him in greater difficulties. The case is exactly analogous to that of a man who deals with a London tailor. As long as his customer pays him a little from time to

time, and is regular in his orders, the tailor never dreams of taking serious measures to recover his debt; but let him find that his customer has gone to another shop, and he has no mercy on him. Similarly when the bunniah sees that his debtor has gone elsewhere for advances, he sells him up at once, and the last state of the wretch is worse than the first. In short, if a zemindar is not prepared to take over the entire responsibilities of a ryot, it is useless giving him an advance; and what this means, any one who has any idea of an ordinary ryot's financial position can easily understand. Further than this, there is a marked difference between the position of Government and an ordinary zemindar, in realizing arrears of *tuccavi* Government under a special law can collect its arrears of *tuccavi* with its revenue arrears without reference to a court. But the landlord is forced (and the tenants know it well) to go through the weary process of executing his decree, and he then comes in contact with an official who is known to the Board of Revenue as a *kurk amin*, but who arrogates to himself the title of "commissioner of sales;" and in truth, his power and influence approximate to those of his brother commissioner of a division. He practically does as he pleases. He has only (for a consideration) to notify to a refractory creditor that he is coming on a certain date to sell him up. The defaulter's effects disappear as if by magic. His cattle pay a visit to a friend. His pots and pans are dispersed among his neighbours, and the expectant creditor when he arrives with "the commissioner" on the ground, finds him sitting in his empty house smoking the *hookah* of contentment. In sales too our "commissioner" is but too apt to sell a bargain to a friend, because he knows that a "Property-Defence Association" is as yet unknown. Until the present procedure of recovering these advances is considerably simplified, it is hopeless to expect Court of Wards estates or independent landlords to give these advances on anything like an extensive scale. The possible solution of the difficulty lies in the extension of the right to distrain standing crops for arrears of *tuccavi*.

BANDA-I-KHUDA.

THE AGRICULTURAL DEPARTMENT.

(*To the Editor of the Madras Mail.*)

SIR,—I have had the pleasure to see in one of your issues, that an Agricultural Department has been started from the 6th instant, and that a Secretary has been appointed to conduct the work with the Government of India. The notification published embodies a long list of subjects that the said department undertakes to direct its attention to. Whether this department is to be worked like the one that was abolished in 1878, or to have a different constitution, I do not know. It would be a mere waste of public money to pay high salaries to Secretaries and others, and render no good to the people for the money thus spent. If this department has been inaugurated *bonâ fide* for the country, something like the American Beaureau of Agriculture would be a real blessing to the country. This idea will not be a new one, for it had its origin in Lord Mayo's time, and afterwards a glimpse of it was caught by that expensive body, the Famine Commission. If such a proposal of the Famine Commission, which has cost more than a lakh of rupees to the country, is to be partially utilized by the mere appointment of a Secretary, to satisfy that political section in England who take some interest in the welfare of India, and argue in the British House of Commons as to the adoption of the suggestions of the Famine Commissioners, merely on the consideration that a great outlay would first be required to carry out all their suggestions connected with the Department of Agriculture, the country would find its finances spent in such a way that no good whatever would be done to the people. The working of the department that was abolished in 1878 might have given an insight as to whether such a department would really benefit the country or not. It would be better therefore to alter the constitution a little by creating local Agricultural Departments, worked by men trained in modern agriculture. These officers should be brought into contact with the native farmers, and show them the real advantages of the systems they advocate. There is a hope still that Lord Ripon will take all the suggestions from the minutes of Lord Mayo, and his Councillors, as well as from the report of the Famine Commission, and thus leave a name behind him.

NATIVE FARMER.

COCOANUT CULTIVATION.

(*To the Editor of the Madras Standard.*)

SIR,—In one of your late issues you strongly advocate "cocoanut cultivation" in Madras, as it would be a source of great revenue not only to the proprietors of the trees but also to Government. Admitting that the juice of the cocoanut tree is useful, yet, the fruit of the trees grown in the town cannot be used for curries or sweets, or in making oil as the cocoanuts grown on the Western Coast or in Ceylon. The fruit of the cocoanut tree cultivated in Madras is never used, and a reference to our cooks will verify my statement. The tender cocoanuts are extensively eaten by Hindus and others during the hot weather, and these are also sold on the roadways and purchased by weary travellers, to whom they are welcome. I am glad that you have mooted the subject of cocoanut cultivation, and hope it will not end here, but that some persons who have funds at their command would carry out the suggestions contained in your article. Had I the means, I would readily take the hint, rather than invest in gold mining and bite my fingers in the end.

T.

CARDAMOM PLANTING.

(*To the Editor of the Ceylon Observer.*)

SIR,—It has hitherto been the custom to plant single cardamom bulbs taken from old bushes. It struck me sometime ago that, as the object was to grow a good bush, a simpler plan would be to put several plants to a hole. I found that it has succeeded admirably. Even seedling plants three to four inches high can be safely put out during the heavy rains. Three to four plants to a hole, and each plant nine inches apart from the others. The young plants threw out several shoots in a few months, and the result is a magnificent bush in a year. The old method is a slow, tedious, and far from a profitable one. The present prices for cardamoms, *properly gathered and cured*, are really very handsome, and should they even go down to a third, the return from an acre of cardamoms is more profitable than coffee yielding two and-a-half cwt the acre. The planting out of this product should be vigorously carried on. It requires a very small outlay comparatively, if the method of planting as above suggested is followed.

R S

"THE PLANTERS' PEST."

(*To the Editor of the Englishman.*)

SIR,—You were good enough some little while ago to favour me with space under this heading, and I must apologise for again troubling you, and begging a repetition of the favour.

In my former letter I noticed the scantiness of the information given us by Mr. Wood-Mason in his telegraphic report upon this subject of blight, but, when doing so, I was certainly under the impression that this report was at any rate only an instalment of the information we were ultimately to receive. It seems, however, that this is not so, and that we have the entire "*ridiculus mus*" laid out *cap-a-queue* before us, and I need hardly tell you what an inadequate meal this is for a hungry though blighted planter.

It seemed at first incredible to us that Mr. Wood-Mason had really deserted us when our heaviest troubles were beginning and the blight was thick upon us. Now, however, it has to be accepted as a melancholy fact that the Blight Inquisition has shut up, closed, and collapsed like a concertina, or a crush opera-hat, when sat upon. Blight victorious chortles in its joy, and there is nothing left the planter and his hopes but to sink into his boots in that damp despondent state which we can easily imagine to be the lot of the sad and unobtrusive periwinkle.

"*Eheu fugaces rupees, nunquam nobis redeundi!*" is the universal wail both up and down the brae.

As it seems useless now to expect the further information sought for in my former letter, I should like to ask what was in fact the end and aim of Mr. Wood-Mason's mission to Cachar. Was it to study the insect from a purely scientific and entomoligical point of view, or, after complete investigation of its general habits, &c., to co-operate with us in devising some check or cure for its ravages on the tea-bush?

If the former, Mr. Wood-Mason is the happy possessor, and possibly discoverer of an insect, probably unique, which, in its maternal large-heartedness lays, as he says, an egg *and* a bristle. (Can this, then, be the reason why a friend signing himself UP YONDER answers my letter in the *Englishman* by one in the *Indian Tea Gazette*, remarking that blight insects are always born twins? or rather, as he playfully writes it, "two in a litter," putting it between quotation-marks which led me at first to suppose the idea was not original, though a little consideration has convinced me it is, at least regarding blight? Seeing, however, the amount of blight we manage to get through here with our more modest insect which only gives us one at a birth—and a bristle—I think myself lucky in living here rather than "up yonder," which I should imagine cannot be a very paying place for tea, and so should recommend my friend to come a little *down* and *hither* (though I scarcely think such funny things take place "up yonder" as he would have us believe!) If the latter, I maintain that his investigations are as yet by no means complete, and that so far he has failed altogether, I do not think that even the most sanguine of Mr. Wood-Mason's

admirers would venture to assert that his report affords any solution of the difficulty. The doubtful cure therein suggested is impracticable and doubly impossible, firstly, on account of the excessive cost involved in working it out in its entirety, and secondly, from the impossibility of procuring the staff required. There remains, moreover, the question whether the cure would not be worse than the disease as regards injury to the bushes.

It there is any doubt as to the points requiring elucidation, I am sure that an application to the planters, directly, or through the agents, would at once bring forth the required information freely. What I regard as imperative in any investigation of this sort, is that there should be perfect co-operation and identification of interests between the investigators. This, I take it, is not a matter and question of pure, but applied, entomology in its relation to the tea industry, and any hasty or partial observations, from either the planter's or naturalist's point of view. taken singly and independently, without regard to each other, or the end aimed at must frustrate that end, and be, in my opinion, both incomplete and barren of result. A bare statement of a few isolated facts concerning the insect, unsupplemented by such information as I suggested in my former letter, is as worthless practically as a similarly drawn up description by a planter of the actual injury done by the pest to the tea-bush would be, so far as finding out a remedy goes.

Given, however the complete life history, and *fons et origo mali*, we can go logically to work, and fix on the most convenient point and mode of attack, if attack be possible. If it is not, we shall at any rate save useless expenditure on experiment and fruitless effort.

Who then is to give us this information? and here, of course, it is to the naturalist we must look, and looked for it undoubtedly should be, and that soon too, if any measures are to be taken and head way made against the blight of 1882, for if any measures be possible, it is only reasonable to suppose that they should be put in force early before the insects grow overwhelmingly numerous.

It would be much to be regretted were the matter now to be allowed to rest, only to be taken up afresh after the loss of much valuable time, and with much old ground to be gone over again. Surely a question involving the loss of say two-thirds or three-quarters of the outturn of two or three months in the height of the season, is a matter of sufficiently serious interest to call for continued effort and perseverance in its handling. Still, if the second half of 1881 be not more fruitful in research than the first, the chance of successful dealing with the pest in 1882 grows very small indeed *Marchons. donc!*

A BLIGHTED PLANTER.

Cachar, August 6, 1881.

THE CROTON OIL TREE.

(To the Editor of the Ceylon Observer.)

SIR,—With reference to the letter of "C. D." to the editor of the *Indian Agriculturist*, published in your issue of 13th April, I now have the pleasure to send you Mr. Whyte's reply.

As regards the croton now growing on this estate, I am able to state positively that it is not a shrub and injurious to coffee or cocoa. On the contrary, the coffee thrives well under and close up to the tree, both the croton and coffee giving good crops. Other statements have been so well answered by Mr. Whyte that it is unnecessary for me to reply further to "C. D.'s" letter.—Yours truly,

J. HOLLOWAY.

June 22nd, 1881.

Kandy, 20th June 1881.

Dear Mr. Holloway,—I have to thank you for sending me the *Observer*, containing "C. D.'s" letter, copied from the *Indian Agriculturist*, in which he alludes to my notes on the croton oil tree *(Croton Tiglium)*. I ought to have replied to your letter sooner, but have been otherwise much engaged.

"C. D." seems to look on the cultivaton of this *noxious weed* (his term for the croton oil tree) as a monstr'ous piece of folly, and "seizes a spare moment to express a hope that no such steps may be taken," ignoring the fact that we in Ceylon should only be following in the footsteps of India, whence the chief supply of croton seed is imported into England.

You will observe that "C. D." in his letter also describes *his* croton oil plant—which by the way *he knows well*—as an ugly sprawling evergreen shrub, frequently used as a *hedge* stick, but which is not stiff enough for the purpose.

Now from this, and the remainder of the description given of the plant he refers to. I feel confident "C. D." is confounding the croton oil trees with another plant—possibly an Indian species of the genus croton. I think, however, the plant in question is much more likely to be the physic nut, *Curcas* (formerly *Jatropha) purgans*, the *Wal Endaru*, or wild castor oil of the Sinhalese, a soft-wooded smooth-barked shrub bearing cymose clusters of three-seeded fruit, or seed capsules of the size of a pigeon's egg.

If I am right in my surmises as to the plant referred to by "C. D.," you will no doubt recognise it at once. It agrees almost exactly with part of the description given by "C. D." It is to be found as an ingredient, I may say, in almost every native *fence*, for in our rural districts we have not yet got the length of *hedges*; and even the term *fence* is a misnomer for the wretched stray sticks that are stuck carelessly in the ground, on the faith that Nature will be kind. We teach Ramasamy a good deal in Ceylon, and we send him back to India with his pockets well lined, but I fear we have not yet taught him the method of making a thoroughly good hedge round his compound. We are, in fact, deplorably behind in hedge culture and the natives in this, as in most other things, are quite satisfied to do as their forefathers did, and will not advance a step.

But to return to the physic-nut plant: it is held in much repute by the natives, both for its purgative and healing qualities. From one to four of the seeds is a dose for an adult, and the milky juice of the plant is applied to wounds and cuts with the best effect. In the West Indies, the leaves pounded up were invariably used as a sort of poultice, and were very efficacious in cleansing and healing foul and obstinate ulcers. It is a native of tropical America, but has been introduced into nearly all tropical countries.

With regard to the croton oil tree, you can speak with more confidence than I can as to its suitableness for shade, as also in reference to its value in a commercial point of view; and should you think it worth your while to put "C. D." right, you are welcome to make what use you think proper of these notes.—Yours truly,

A. WHYTE.

The Indian Agriculturist.

CALCUTTA, SEPTEMBER 1, 1881.

MAIZE.

THIS cereal is second only in importance to rice. It is grown largely throughout the American continent, from Canada in the north, to Patagonia in the south: throughout the islands of the Pacific, in the West India Islands, in Australia, throughout the whole of Africa, in Spain, Portugal, Southern France, Italy, Hungary, Turkey, Greece, Asia Minor, Persia, Central Asia, India, China, and the islands of the Indian Ocean. To use the words of the author of "Tropical Agriculture," "no grain could secure such favors from all parts of the world, except from its intrinsic value. Its flexibility of organization makes it easy of adaptation to climate and soil. Though it perfers moist and rich soils with strong heats, there are varieties of it which can be raised in tropical climates at a height of more than 9,000 feet above the level of the sea. The warmest regions of the Torrid Zone produce maize in abundance where three crops can be taken in a season, while the short summers of Canada have a variety suited to them. This cannot be said of rice which requires great heat and cannot endure a climate of a high latitude."

Two analyses by Professor Emil Wolff give the composition of maize :—

	No. I.	No. II.
Water	... 14·4	9·0
Ash	... 2·1	1·22
Albumenoids ...	... 10·0	10·00
Carbo-hydrates ...	... 68·0	71·40
Crude fibre ...	... 5·5	3·40
Fats, &c. ...	... 7·9	4·98

The following table gives the ash constituents of the grain :—

Potash	... 28·37
Soda	... 1·74
Chloride of soda	... trace
Lime	... 0·57
Magnesia	... 13·60
Oxide of iron	... 0·47
Phosphoric acid	... 53·69
Sulphuric acid	... trace.
Silica	... 1·55

Maize is little if at all inferior to wheat in nutritious *qualities*, and "the ingredients concentrated by Nature in a grain of corn are all essential to a highly nutritious food. The g uten and mucilage contain nitrogen, an element essential to the formation

of fibrous muscle, nervous matter and brain. The oil is nearly formed fat, easily convertible into animal oils by a slight change of composition. Starch is also convertible into fat, and into the carbonaceous substances of the body, and during its slow combustion in the circulation gives out a portion of the heat of animal bodies; while in its altered state it goes to form a part of the living frame. From the phosphates are derived the substance of bone as well as the saline matter of brain nerves, and other solid and fluid parts of the body. The salts of iron go to the blood, and these constitute an essential portion of it, enabling it by successive alterations of its degree of oxidation during the circulation through lungs, arteries, extreme vessels and veins, to transport oxygen to every part of the body. Indian corn therefore contains all the elements for the perfect development and support of the bodies of animals. . . . . . Indian corn is one of the most important and healthful articles of human food that a beneficient Providence has bestowed on man, and to its high nutritive value is due in a large degree, the strength and vigour of the race of men who laid the foundation of the great American Republic."

The uses of Indian corn are numerous. It serves as food for nearly one-third of the human race. As a fodder for cattle, horses, sheep, swine, and poultry it is invaluable. The dried cobs and stalks serve as fuel, and in South America a kind of beer is largely distilled from the corn.

In Germany, Austria, and Hungary, a very superior kind of paper is made from the leaves and sheaths of the cob, and it is to be hoped that the day is not far distant when English capital will be forthcoming with a view to establishing this industry in India. "Maize paper" has none of the brittleness peculiar to ordinary straw paper. Maize paper appears to be the most unexceptionable of all the papers *not* made* from rags. Not only is it remarkably tough, but it is devoid of all the silicious matter which proves so embarrassing in ordinary straw paper causing great brittleness when folding and rapidly destroying the face of printers' type. The extreme toughness of the paper makes it particularly eligible for Bank-note paper, and for the purpose of envelopes. The color is somewhat yellowish, but it is easily bleached."

In India, maize is a summer or *kharif* crop. Where irrigation is available it is sown in May or the end of April, but otherwise not until the monsoon sets in. After the first showers of rain the ground is ploughed up, the surface of the soil being scarified by a native plough. Manure insufficient in quality and quantity is ploughed into the soil, and the seed sown in parallel rows about one foot apart. A heavy beam of wood called a *swaga* drawn by two bullocks is passed over the field to close the furrows, and the seed is left to its own devices. As soon as the plant has attained a height of about five or six inches above ground, the field is hand-hoed; this operation being repeated twice or thrice. About the beginning of October the crop is cut, and large sheaves are heaped up all over the field, after standing for a week or ten days the cobs are broken off, the stalk and the grain *shelled*. The native method of shelling is truly barbarous; three, or four men sit round a heap of the cobs and beat the heap with short heavy sticks, an immense amount of grain is thereby lost and damaged. The average yield seldom exceeds 25 to 30 maunds per acre. The amount of seed sown does not fall short of 25lbs. per acre.

In Algeria the mean yield on unirrigated land is 20 cwt. per hectare (2·471 acres) whereas in American maize cultivation has attained its highest development, an ordinary crop is 60 bushels and 100 bushels. or 75 maunds is not an uncommon yield. 130 bushels or 7,800lbs. per acre have been raised.

The New York State Agricultural Society require a yield of 80 bushels of corn to the acre to be entitled to a premium.

The results of two experiments on the Saidapet Model Farm are herewith given.

No. I.

MAIZE EARLY AMERICAN.

General nature of soil ...	Sandy loam.
Area of land sown	2·88 acres.
Cultivation of soil before sowing	Twice ploughed, harrowed and ridged, and again ridged over manure.
Kind and quantity of manure used	42 loads of farm-yard dung.
Pounds of seed sown... ...	18lbs.
Date of sowing	21st September.
Cultivation during growth of crop	Twice hand-hoed.
Rainfall and number of wet days recorded during growth of crop	31 wet days, 24·00 inches.
Date when harvested ...	29th December.
Number of cobs	7,390.
Weight of straw when dry ...	5,824 pounds.

The foregoing it must be remembered is the produce of only half the ground, as the maize was sown in lines alternately with lines of cotton.

The weight of manure is not given, but allowing 20 maunds per load, it would be a little over 10 tons per acre.

No. II.

MAIZE "YELLOW FLINT."

General nature of soil ...	Sandy loam.
Area of land sown	1½ acre.
Cultivation of land before sowing	Ploughed, harrowed, and ridged.
Pounds of seed sown ...	19 pounds.
Date of sowing	28th September.
Cultivation during growth of crop	Twice hand-hoed.
Rainfall and number of wet days recorded during growth of crop	31 wet days, 24·00 inches.
Date when crop was harvested ...	5th January 1876.
Number of cobs	4,050.

The remarks made with reference to the area of land actually cropped apply equally to both experiments.

It is impossible to enumerate the different kinds of Indian corn grown in various countries; though two hundred varieties were shown at the London exhibition of 1862.

Professor Symmonds enumerates seventeen varieties grown in North America. "They may be distinguished by the number of rows or grains on the cob, and the size, colour, shape, &c., of the kernels." He evidently gives the first place to "Golden Sioux" or "Northern flint corn" having a large cob with twelve rows of moderate sized grains very oily. This is regarded as one of the best varieties for fattening animals or for human food. By skilful tillage 130 bushels have been raised to the acre weighing 9,216lbs. in the year; when dry, 75lbs. of ear gave a bushel of corn shelled. The soil best suited is a light sandy loam, clay is not good. The following is an extract from a letter from a gentleman, a planter in Natal, on the subject of maize cultivation.

"The kind of maize we prefer out here is that known as the "American Horse-toothy Mealy." With proper cultivation we can easily raise as much as 70 to 75 bushels per acre, and the meal produced is excellent food for both man and beast. We go in for deep ploughing and liberal manuring. The rows of corn are struck out 4'-6" to 5' apart, and the plants 12" to 15" apart in the rows. As soon as the plants appear above ground, say 6 or 7 inches, we give them a top dressing of ashes and lime or superphosphate,* heaping a little earth round each plant, and converting as it were the surface of the field into so many small hillocks. We then run a horse hoe between the rows keeping the land free from weeds, and the same time preventing the soil from caking or hardening. We do this about two or three times. In about 10 weeks the crop shows sign of maturing, and is generally off the ground in about 90 to 100 days from date of first sowing.

With regard to maize cultivation, Professor Symmonds gives the following hints :—

"After thorough preparation of the soil by deep and subsoil ploughing, and the addition of such amendments as analysis may prove to be necessary, the corn should be planted out at slight depths in *hills* 4 feet apart in every direction, which will admit of more thorough cultivation in both directions than if planted in rows. I cannot but suggest that in the final preparation of the soil before planting, it could be better to run the subsoil plough at a full depth in sticking out the rows; this having been done in both directions, will leave the intersections visible for the planting of the corn. From the peculiarity of this plough the soil will be left in a more divided condition than if turned over by the surface plough alone. In these intersections the corn may be planted. When 3 inches high, the lifting subsoil plough which will affect the soil at the surface for two feet on each side of this line of travel, should be run in one direction half way between the rows of hills, thus disintegrating the soil in the centre to the full depth, disturbing it at the surface to the very plants, gradually lossening as it approaches them, so

* NOTE.—In the last report on *rabi* operations, Cawnpore Farm, full information is given as to cost and mode of preparation of superphosphate.

that none of the young roots are abraded by its action. It will now be seen that immediately under the corn is a deep disintegration readily accessible to the roots, while the space between the hills is thoroughly pulverised and deepened as it recedes from the hills, so that the roots will not be inclined to travel surface-ways. At the proper time for a second ploughing, the lifting subsoil plough may be run in the opposite direction half way between the rows, thus rendering the soil pulverulent to a great depth at a later stage of the growth. The after cultivation may be conducted by the universal cultivator set the whole width of 4 feet, or so near it, as not to disturb the plants, and to such depth as will keep the entire surface free from weeds and open for the admission of the atmosphere. The running of this cultivator once in each direction will be found to be more efficient than the ordinary use of the hoe, and at the same time securing flat cultivation.

"At the first application of the cultivator, or lifting plough, stimulating manures may be applied to each hill with safety, and we have known many instances where 100 bushels of shelled corn per acre have been produced by the application of two ounces of improved superphosphate of lime to each hill, at the first hoeing or first cultivation. The result seems to be larger when stimulants are thus applied, than when placed in the soil before planting. Indeed when guano or any other stimulating manure is used, it should be at the first disturbance of the soil after the corn is above ground, rather than before the planting of the seed. Some growers prefer to plant the corn in hills as already named running a *Universal Cultivator*, with the two rear share-teeth reversed, between the rows, when the corn is three inches high. This throws a light furrow from each row, in which special manure may be applied; a small subsoil plough should then be run with the flat side towards the corn, the wings of the plough removed, so that the lifting action of the nose will only be applied to the soil. This should be repeated on each side of the row so as to disturb the soil to a depth of ten inches before the roots are sufficiently grown to be abraded, and this loosening will thoroughly mix the manure with the soil. The rear teeth of the cultivator may then be reversed and run again between the rows so as to replace this narrow furrow, leaving the soil flat. In place of a second hoeing at the usual time, the horse-hoe may be run in the opposite direction, clearing the ground of weeds and leaving the soil clean and pulverulent."

The high yield and general excellence of American maize may be ascribed to :—

I. Careful selection of seed.
II. Judicious and complete preparation of the soil previous to planting the corn.
III. Deep ploughing and careful after cultivation, such as elimination of weeds, &c.
IV. Liberal manuring with organic manure followed by top dressings of mineral manure.

In Indian agriculture these conditions are conspicuous by their entire absence.

Selection of seed. Obviously the best method is to select the best and healthiest plants in each field, and from these plants take the largest and best filled cobs, two or three years' careful seclection with even the most *degenerate* country-seed would result in a quality (provided all other conditions be maintained) bearing four, five, and six cobs to each plant.

Preservation of seed. The natives of this country do not attempt to keep their maize seed in store more than one year, and during this time it is kept *on* the cobs, and the cobs covered with ashes in earthen air-tight vessels—to prevent insects and ants attacking the grain, the mouths and covers of the vessels should be smeared over with carbolic acid.

Mr. Robertson, Madras Agricultural Department, suggests that "to prevent crows and squirrels, &c., destroying the seed, tar it before sowing. Take 1½ pint of water, 1/12 pint of tar mix together and when cool, pour the solution over the seed. After dusting sand, ashes, or sawdust, to prevent the seed adhering together, the grain is ready for sowing."

Ploughing and cultivation. The best plough for India is the Kaisar, and the changes which have been rung on it by different patentees in various parts of the country. The Kaisar, the Ryot, the Kashtkar, &c., are all modifications of M. M. Ransomes Sims and Head, primitive and Egyptian ploughs costing in England about £1-10. The patentees have, however, modified their inventions to suit the requirements of the ryot and his cattle, they give a deep tilth with a light draught and are very effective, tearing out weeds, roots, &c., with great ease. This form of plough varies in cost from Rs. 5-5 to Rs. 9. Five or six ploughings with this implement is equal in effect to twenty grubbings with the best native plough.

Constant and repeated weeding is required for maize. Maize should get at least 20 tons of farm-yard manure per acre supplemented by about 2½ to 3 cwt of mineral manure applied as a top dressing after the first hoeing and previous to ridging up with a ridging plough. A ridging plough with double mould board on the principle of the "Kaisar" can be made up for Rs. 9.

Good bone dust manure costs about Rs. 7-5 per maund, varying of course with the price of sulphuric acid, which in Upper India is seldom less than 8 annas a pint. A mixture which has been found to answer remarkably well consisting of wood ashes, bone dust (calcined bones) and common salt in the ratios of 6-3-1 respectively, is much cheaper (about Rs. 4 per maund) though not so powerful a fertilizer as if composed solely of bone dust. The bones are calcined then pounded, and afterwards treated with sulphuric acid and hot water; wood ashes and salt are then added and the substance fit for use. About two ounces of the manure to each plant will produce excellent results, four, five, and even six cobs to each shoot.

With careful cultivation and judicious treatment, the Indian species would soon exhibit the excellence of the American maize or South African mealy.

The cost of cultivation and produce per acre, would, in the hands of an intelligent cultivator, approximate close to the following figures :—

Cost of Cultivation.

	Rs.	As.	P.
Government Revenue	1	0	0
Seed 20lbs.	0	8	0
Manure 20 tons	12	4	0
Ploughing, ridging, weeding, and after cultivation ...	10	0	0
Harvesting crop	10	0	0
Mineral manure 3 maunds @ Rs. 4 per maund ...	12	0	0
	45	12	0

Value of produce.

	Rs.	As.	P.
Grains 60 maunds at Re. 1-5	90	0	0
Straw fodder 120 maunds at Re. 0·25 per maund ...	40	0	0
	130	0	0
Balance in favor of cultivator 130 minus 46= ...	84	0	0

Attempts have been made to introduce the American varieties into this country, and not without success: though it could be as well to bear in mind that one or two years of rational cultivation would soon bring the native maize in point of excellence up to the finest imported species. One of the greatest mistakes made and *the* rock on which most agricultural experiments in this country have split, has been the attempt to introduce and force upon the natives, foreign species at the expense of the indigenous staple.

Mr. Fuller's experiments with fodder crops at Cawnpore have shown that the sorghum only requires careful cultivation to equal, if not surpass the once far-famed *Teosinte* or *Reana Luxurians* according to Mr. Fuller, reana can not hold its own with "sorghum."

When these foreign species are introduced and distributed to intelligent natives, it is seldom that precise and accurate directions are given as to the method of cultivation, or if instructions are given no native would for one instant dream of carrying them out, the consequence being that with shallow cultivation and deficient manuring the highly organised species degenerates at once, and the much talked of *Valaiti Tukhm* is found on developing into a full grown plant to yield a produce little superior to, if as good as the ordinary country staple, and the native never dreaming or caring to admit even that the fault was *his*, for the future, discredits the imported seed, and "will have none of it." Every Indian staple, maize, rice, wheat, sorghum, sugar, and cotton, one and all under a system of rational cultivation, can be rendered capable of the highest development, and that in a relatively short space of time. Let the new Department of Agriculture bear this in mind, using its best endeavours to attain this end, and an agricultural reform of great importance will then have been effected.

25th July 1881.

WHEAT IN THE CENTRAL PROVINCES.

THE Central Provinces Government more liberal than that of the Berars, offer land free for three years, and after that term at a nominal rental on the sole condition that the holding is brought under cultivation and villages established. Cotton would flourish in all these parts, but if we turn to the item of wheat, the result would be very satisfactory indeed. Samples from Hârda (a subdivision of the great Hoshungabad district) examined by experts in London, proved among the best qualities in six hundred samples sent from all parts of the world.

There is no very heavy jungle except at the foot of the hills, so the land picked out would be in scrub and grass near a station of the G.I.P. Railway, and the cultivation of 400 acres would stand in something like the following expenditure and results :—

	Rs.	A.	P.
Clearance of whatever jungle exists, scrub ...	600	0	0
Purchase of 10-pair bulls @ Rs. 40 per pair ...	400	0	0
Ploughing, gear, &c.	100	0	0
Feed and keep of 10-pair bulls, while 4 months at work	450	0	0
Keep of cattle 8 months, 2 men @ Rs. 5 per month each	80	0	0
Purchase of 300 maunds seed wheat @ 2 per maund	[illegible]00	0	0
Expenses, sowing, harvesting, &c.	500	0	0
Management @ Rs 50 per month	600	0	0
Contingent and incidental expenses, chowkidars, &c.	270	0	0
Total expenditure, Rs. ...	3,600	0	0
Outturn of wheat at the rate of 12 maunds per acre from 400 acres 4,800 maunds sold at factory @ Rs. 2 per maund	9,600	0	0
Balance Profit, Rs. ...	6,000	0	0

Here we have a profit of Rs. 6,000 on an outlay of Rs. 3,600. We have left quite out of consideration the wheat straw greedily devoured by cattle and sold at a most remunerative rate. Now since the vital, &c., &c., (as per MS. sent formerly).

Now since the vital question of finding employment for Baboos on this side of India, and Brahmins on the other has been settled by placing at their disposal all posts in the gift of the Government of India and their subordinates; and encouraging them to aspire to most of the pet emoluments however lofty, perhaps this Government will be gracious enough to condescend to inquire how the ever-increasing Anglo-Indian and Eurasian races are to earn a bare subsistence, especially as the ground has been cut away from under their feet both by the State and Railway Companies. Sooner or later this burning question must be attended to, and it behoves the authorities to brace themselves up and face the matter before it assumes more threatening and complex proportions. And since the training ships about to be established, and the regiments that must be organised, cannot absorb all the material available, it would be just as well for Government to inquire whether a grand scheme of colonisation is not feasible in these and other suitable parts of India for these races, with State help, and this is not too much to expect seeing the Central Provinces Government are every day assisting new native settlers with money for stocking purposes and their own support.

With such a chief as Mr. Buck in the resuscitated Department of Agriculture, the scientific as well as practical fosterer of every branch of husbandry, is it too much to expect that some such scheme will be organised, and so solve a great difficulty, held a patient and most deserving people as well as aggrandize the State.

REH.

"AGRICULTURIST" wrote asking for information about *reh*. We have pleasure in placing before him and our readers the gist of the result obtained by a committee appointed to investigate the subject, and which has been courteously placed at our disposal by a correspondent.

AGRICULTURIST is informed that the committee met at Aligarh in 1878 for investigating questions connected with the deterioration of land under the influence of *reh*, recommended Government to place the scientific investigation of *reh* phenomena, under a special officer, on which Mr. Wilson, C.E., of the Irrigation Department, was specially selected by Colonel Brownlow, the Chief Engineer, P. W. D., and he joined the Agricultural Department in the month of August 1878.

Last year Mr. Wilson lost no opportunity of adopting systematic measures to purify the land now sterilized by *reh* in the *usar* plains in the Awa Estate, district Agra. He planted out 64 acres with trees at the cost of Rs. 2,092, on five different systems, which are as follows :—

"(I.) Holes were dug 3' deep, 3' wide at top, and 2' wide at bottom, and then refilled with the soil that had been taken out of them. Good soil was added to some of the beds.

"(II.) Holes were dug of the same size as in (I.), and the soil was inverted, the earth excavated from one hole being thrown into the next. Good soil was added to some of the beds.

"(III.) Holes were dug 2' wide and 2' deep, and the soil inverted.

"(IV.) Channels were dug 1' deep, by 1' 6" broad at the top and 9" broad at the bottom, and the soil made into a ridge on one side. Part of the ground was ploughed before the channels were dug. Seeds were sown on the ridge.

"(V.) The ground was first ploughed with one of Ransome and Sims' B. F. O. ploughs, and then prepared in a series of ridges 6" high and furrows 6" deep. The ridges were 10 apart."

* * * * * * * * * * * * * * * * * *

"Of the plans described above, the last three have completely failed; no seeds having germinated, except in a few patches * * * * *. Of the beds prepared on the first plan about 5 per cent., and of those made on the second plan about 15 per cent., now contain plants. The latter is the system recommended by Mr. Greig in his note on the Purdilnagar *usar* plantation in the Aligarh district. * *

* * * * * * * * * * * * * * * * * *

"In February 185 shisham trees were planted 40' apart in the Awagarh plantation. The trees were one year old and 5' to 7' in height. About 80 per cent. of them appear to be doing well. They are watered by means of pipes 3" in diameter and 18" long, fixed vertically about 6" from the trees. * * * * * * * * * * * * *

"The failure of the *kikar* sowing last July should, I think, be attributed entirely to the scanty rainfall. Owing to the accumulation of saline matter in it *usar* soil is very impervious to water, and the light rain of July to September did not penetrate to any depth below the surface; the plants, consequently got very little moisture. Some of the plants which came up from the seed first sown in June, and had the full benefit of the rains have done well, but they are generally in the lower parts of the ground where the water remained longest. I feel certain that had the average quantity of rain fallen, the plantations would have proved a success.

* * * * * * * * * * * * * * * * * *

"A number of plots of *usar* were prepared and treated with artificial manures in the manner suggested by M. Ville. Wheat was sown in six, and peas in the remaining five. Owing to the scanty rainfall and the hardness of the soil, it was necessary to irrigate the ground with canal water before it could be properly prepared. The canal was closed till late in the season, so that the plots were not sown till near the end of November. The ground was ploughed with Ransome and Sims' B. F. O. plough, and once with a country plough before sowing. The seed germinated poorly, but about equally, in all the plots, but the plants made no progress; their leaves turned yellow and most of them died. A few plants scattered over the plots are still living, but are less than 6" high. Half of each plot was irrigated once in January. Other plots prepared in the same way treated with stable manure and indigo refuse and sown with wheat and peas have also failed to produce a crop.

"In order to find the best manure for *kikar (Acacia Arabica)*, a piece of cultivated ground on the borders of an *usar* plain was taken up. Stable manure and indigo refuse have proved decidedly more effective than M. Ville's artificial manures.

"I may mention that I did not anticipate much benefit from the application of mineral manure to *reh* soil, which already contains an excess of saline matter, but tried it to make the experiment more complete.

"Various experiments have been and are being tried in order to remove the *reh*.

"(I.) *Surface drainage.*—A plot of land previously ploughed with Ransome and Sims' B. F. O. plough was prepared in a series of ridges and furrows * *, the ridges being 10' apart, and the height from bottom of furrow to top of ridge 1'. In another place of land small channels were dug * * * * * * *, the earth excavated being used to raise the ground between the channels.

"It was hoped that the rain would wash the salt out of the ridges into the furrows and channels. There certainly appears to be more *reh* in the furrows than in the ridges, but the latter are not yet clean enough for [illegible]. Indigo and [illegible] were sown on the ridges during the rains; a few seeds germinated, but the plants died before they were 6" high. The ridges were then manured with mineral

manures, farmyard manure (10 and 21 tons to the acre), and indigo refuse (10 tons to the acre); wheat and barley were sown, but the plants that appeared very soon died.

"(II.) *Scraping the reh off the surface.*—A piece of ground that was treated in this way before the rains, had decidedly less efflorescence in January than the surrounding land. * * * * * * * * *

"(III.) *Sub-soil drainage.*—Under this head two experiments are in progress:—

(a.) By means of pipes, on the system so largely adopted in clay lands in England. For this purpose 4,000 two-inch pipes with collars have recently been given to the department by Mr. MacDonald of Aligarh.

(b.) By opening up the surface soil, so as to allow the rain-water that falls on it, or the canal water that is used to flood it, to penetrate to the more porous subsoil."

* * * * * * * * * * * * *

"A provincial *reh* map is being prepared, showing the area of *usar* in each village, whether efflorescent or not, which should be very useful in dealing with the general question of *reh* and its causes."

The effects, which the subsoil drainage systems have on the physical properties of the soil, have been fully treated by Mr. Hume in his "Agricultural Reform" (pages from 85 to 88) of which it is believed AGRICULTURIST has a copy.

We offer no apology for making such a lengthy extract from Mr. Wilson's Report on *reh* experiments, because we believe it contains the fullest and the most valuable information available regarding the experiments which are now in progress, with *reh*, and it will give a clear idea of the experiments to AGRICULTURIST and the public who are misinformed with him. It will also shew that the Department of Agriculture is aware of its duty and is working in the right direction, without the pointing out of AGRICULTURIST. Although the result of the trials have had but little success, yet the patience and thoroughness with which Mr. Wilson is carrying out his investigations, are sufficient guarantee that success will surely crown his efforts to find some means for removing *reh* from the *usar* plains of the N.-W. P. AGRICULTURIST is also informed that the Assistant Superintendent of the Cawnpore Experimental Farm, instituted some experiments to reclaim *reh* infected lands in the village of Shahpur on the banks of the Ganges Canal in the Rawalpur Estates.

EDITORIAL NOTES.

IT the year 1788 there were only 29 sheep in Australia; at the present time there are no fewer than 62,000,000.

THE amount realized by the City Municipality (Poona) by the sale of night-soil manure, for the past month (June) was Rs. 1,019-2-4.

THE estimated number of cows in the United States is 12,000,000. The product in butter, cheese, and milk, including what is used on the farms, is estimated at $400,300,000.

THE toad destroys from twenty to thirty insects in an hour, and the mole is continually destroying grubs, larvæ, palmer worms, and insects injurious to agriculture; no trace of vegetation is ever found in its stomach.

IF, as is often the case, it is desired to apply a fertilizer that will enrich the land for a number of years, it is necessary to select one that is not all immediately available for plant-food. In this case barn manure would be better than quick acting commercial fertilizers.

AN American farmer says that a gill of gas tar mixed in a pail of whitewash, and applied with a brush to the houses and roosts of poultry will destroy or drive away any lice that may infest them. This is easily tried and has the merit of doing good, whether in the direction intended or not.

INDIANA reports of the bee industry for 1879 (the latest given) show 145,827 colonies, yielding 1,107,627 pounds of honey, or 8·18 pounds per colony. The season was regarded as yielding only half the average annual produce. Lake stands at the head of all the counties, with 59,984 pounds of honey.

THE new Agricultural Department should take notice that a certain bee-fly, belonging to the family of the *bombyliidæ*, is, in its larval state, exceedingly partial to locust eggs, and this useful appetite, according to researches made in America by Professor Riley, may turn out to be a certain remedy against the perpetuation of a plague of locusts.

THE Macoupin county (Ill.) *Enquirer* of April 1, contains a report of the wheat crop in every township in the county. The acreage is reported at ten per cent. increase over the preceding crop, but the severe weather of the past week is supposed to have caused a damage equal to 15 to 25 per cent. The outlook is not regarded so favorable to farmers as was the case at the same time last year.

THE past year will be memorable for the enormous efforts of America, which sent to the United Kingdom 10,400,000 qrs. of what and 3,930,500 sacks of flour, besides a large supply of Indian corn. The cost to the United Kingdom of its wheat and flour imports from all quarters was about £40,000,000 sterling, for which sum rather over 12,000,000 qrs. of wheat and 4,000,000 sacks of flour were obtained.

WE learn from several agricultural journals that by watering plants with water in which sulphate of iron has been dissolved, most extraordinary results may be obtained; beans for instance will grow to double their size, and acquire a much better taste; the same is the case with pears and other fruit. Water kept in a tub with a quantity of old nails in it may also be used for watering with good effect.

PEOPLE whose efforts to maintain the "balance of vice" lead them, like Charles Lamb and Mr. Labouchere, to smoke, will notice with interest that the Spanish Government has decided to abolish the State monopoly of tobacco in Manilla and the whole Philippine Archipelago. The Madrid statesmen expect that this reform will attract foreign capital; and if it improves the Manilla cheroot up to the old standard, smokers will rejoice. The prospects of the Indian industry, however, may possibly suffer.

THE *Madras Standard* tells us that it is proposed to start a fourth cotton mill in Madras, and offers an opinion that there is room for two or three more. There can be no doubt of this. Besides the quantity of twist which Madras exports, there are no fewer than 247,877 private looms for cotton cloth in the presidency, the owners of which will never use hand-made twist, when the machine-made article is placed within their reach, the latter article being much more regular as to count—an important matter in the manufacture of cloth.

WHILE cordially approving of the appointment of Mr. Buck to the new Agricultural Department, we must be permitted to hope that he will not be confined to his desk. Too much office work is required in India and for Mr. Buck to be tied to his desk would be a fatal mistake. His talents would be quite thrown away at such work, and we trust arrangements may be made, whereby he may be able to move about the country as much as possible. The appointment of a thoroughly competent Registrar to the office ought to relieve Mr. Buck from office details, and give him time for work which would be of much greater service to the department.

WE believe that the Maharajah, in consultation with his Minister has had in consideration a scheme for the introduction of an Agricultural Department in connection with the Government of Mysore. Such a scheme cannot but recommend itself to all well-wishers of the country, and there should be no delay in carrying it into effect. Mysore is pre-eminently an *agricultural* country, and all the resources of the province in this direction should be carefully developed. The country has suffered fearfully from famine, and we are now threatened with a scarcity again, and it is high time measures were taken in hand to check the ravages of the giant monster by looking after the agriculture and irrigation of the province, which we take to be the only effectual remedies.

THE subject of ostrich farming is causing some interest in the Mauritius, this industry having been introduced by a wealthy landed proprietor, Mr. Chery Lienard, who imported several pairs of birds from Arabia and the Cape. These ostriches have already hatched breeds; and as there is plenty of barren land on the coast of the island, it is probable that, before many years pass ostrich farming will be an established industry in Mauritius. The Cape papers are eagerly searched

by the Creole and French colonists for items in regard to the rearing and sale of ostriches, &c., and a translation in French, from a Natal paper, has just been published in the *Cernéen*, the leading French journal of the colony, reporting the sale of some pairs of these birds at from 50 to 87½ guineas per pair.

GOLD and cinchona are so completely engrossing the attention of planters on the Nilgiris, and in the Wynaad, that coffee is lost sight of. The fall in price in the home market of this commodity has not helped to raise the hopes of coffee planters. New ventures are not heard of now, and extensions are few and far between. Indeed estates are being offered for sale at prices which, a few years back, would have been reckoned less than half their value, without finding purchasers. A similar depression following a fall in price that has not been since reached, occurred in 1867-68. Some of the best coffee on the hills then sold for Rs. 540 a ton. We have therefore no reason yet to despair as prices have not got so low. It is noticeable that some fine coffee properties have not *yet* blossomed, and those that have blossomed, carry a very poor crop. Our remarks apply to the Southern district particularly.

THE best results are anticipated from a small parcel of seeds of a new East African India-rubber plant which Dr. Kirk, of Zanzibar has collected during a journey from Dar-es-Salaam and sent to India. So successful has been the cultivation of South American rubber-bearing plants in India, that any efforts to increase the variety of trees producing this valuable material deserves recognition. Dr. Kirk says that the particular plant of which he procured the seeds occurs in great abundance along the road towards Nyassa. An important observation made by him is that the supply seems to be but little affected, except in the immediate neighbourhood of villages, by the reckless mode of tapping employed by the natives when collecting the material. Dr. Kirk adds that in many parts a native many still collect three pounds of rubber in a day. With careful cultivation and proper modes of collecting the produce, this plant ought to prove an invaluable addition to Indian commercial products.

THERE is one thing about the Cotton Mills of India which we are surprised has not struck the minds of shareholders, and it is the comparatively small size of factories in India. At home 200,000 spindles is not an unusual number for one factory, whereas here we have a much small number. For instance the mills in and around Calcutta have the following spindles :—

Bowreah	**42,800**
Bengal	**30,276**
Goosery	**26,402**
Dunbar	**21,000**
Empross	**20,000**
Average spindles ...	**28,095**

This number is quite sufficient to pay; in fact a mill with 10,000 would return a dividend, but if these mills had 100,000 spindles each, their dividends would be much more satisfactory, as a production of a lb. of twist would cost rather less when the larger number were at work. Management would cost less comparatively, and many other items would be relatively cheaper.

IT has been determined to reduce the charges for water for dry crops, under the M. I. C. Co. Canal, owing to the failure of rain in the neighbourhood. The crops sown are in danger of perishing, but the ryots are so dilatory that without some strong incentive they will probably wait till the mischief is done, before they stir. In the famine years, it was found necessary to make great concessions to them, but too late. This year they are promised the water at eight annas an acre, or a quarter of the usual charge. This is perhaps a step in the right direction, but we do not anticipate much increase in the use of canal water until payment is made compulsory. We should ascertain carefully the limits of a district in which canal water is available, and then make the payment of a canal rate compulsory. A much lighten charge per acre that obtaining would suffice, when all had to pay. The idea of a compulsory charge is not harsh, as in a little consideration, it will be seen that where water was generally used, famines would be practically impossible. Where a district is visited with famine, imperial taxation has to be raised to meet the difficulty, and it would be a much more sensible plan to raise this tax for the purpose of preventing famine. We know how dilatory the ryot is, and how unwilling he is to spend a penny, but when this failing of his leads to a famine, and its attendant horrors, there can be no objection to exerting a little pressure by way of prevention.

THE novel proposal (the *Times* learns from the *Scientific American*) has been made by an enterprising Frenchman to the trustees of the Mammoth Cave to rent a portion of the cave for raising edible Fungi. He has been cultivating mushrooms in the neighbourhood of New York, but complains of want of cellar space, and of the conditions of temperature and moisture as not uniform enough for the best results. The portion of the cave which he has in view is that known as Audubon's Avenue, the first passage to the right after entering the cave. It is about half a mile long, and contains little of special interest, unless it be the swarms of bats in the Great Bat Room. The rich deposits of bat guano that have accumulated there for centuries would no doubt prove serviceable, when mixed with other fertilisers, in growing the Fungi. The soil is at present very dry, but might easily be moistened to any desired degree. The idea of thus utilising caverns has long been a familiar one, and practically realised in France. One cave at Montrouge is said to have six or seven miles run of mushroom beds; another, near Frepillon, sixteen miles; a third, at Mery, over twenty-one miles. The special advantage of subterranean culture lies in the uniformity of temperature, which in the Mammoth Cave hardly varies from 56° Fahr. all the year round. Mushroom culture is found highly remunerative. It is thought choice mushrooms would find a ready market in Louisville, Cincinnati, and other western and southern cities, not to speak of more distant markets. The project in question is thought to be regarded favourably by the trustees.

HEAVY rain has fallen lately in the Central Provinces. In Sumbulpore 4·42 inches fell in one week; in Raepore 4·27 inches; in Warda 4·83 inches; in Jubbulpore 4·4 inches, and in Bhundara 8·06 inches. The rice transplanting is making rapid progress, and other crops promise well. The weeding of the cotton crop goes on apace, although in some parts this crop has suffered through excessive moisture. In several districts the satisfactory prospect is having its effect on the prices of food-grains, which are now selling as follows in seers per rupee :—

	Rice.	*Wheat.*	*Jowar.*
Sumbulpore	47	...	...
Raepore	38	40	...
Chanda	14½	22½	32½
Mandla	20	31	30
Bhundara	16	23¾	27
Seoni	18	28	...
Khandwa	...	21	44
Hoshungabad	8	20	30
Jubbulpore	13	24	...

Public health continues good; and as might be expected from the general prosperity of the district, the material condition of the people is satisfactory.

THERE can now be but little doubt that within a few years not only will the Australasian Colonies be able to supply their own sugar, but a considerable export trade will spring up along the shores of the Pacific. Some time since we drew attention to the fact that Fijian sugar was bringing almost as high a price in Melbourne as the best Mauritian produce. Indeed, we have Mauritian testimony to the adaptability of Fiji to sugar-growing; for the Director of the Port Louis Botanical Gardens, when visiting the group, was struck with the conviction that Fiji might be the aboriginal home of the cane, which he found covering extensive areas with a luxuriant growth. We learn that 45 tons of cane, giving two tons of sugar, are an average yield; and, with these facts before us, we are not surprised to hear that the Colonial Sugar Company is commencing operations on a large scale, and has already despatched a steamer from Sydney laden with plant and carrying eighty mechanics and labourers engaged to erect a large mill on the banks of the Rewa River, some twelve miles from its mouth. A large area has already been planted with canes, and the machinery, manufactured in England, and weighing from 2,500 to 3,000 tons, is now being shipped out to the group. From 80,000*l.* to 100,000*l.* will be sunk in the company's works and floating stock, and when in full work the

mill will be capable of turning out some 350 tons of sugar per week. As far as sugar is concerned, Fiji should soon merit the title of the "Mauritius of the South Pacific;" but the Australian Colonies are fast increasing their area of land under cane. The Executive Council of South Australia has already allotted to applicants 100,000 acres of land in the Northern Territory, on the Adelaide and Daly Rivers, and between Port Darwin and Byron Harbour, and a number of enterprising young colonists are turning their attention in this direction.

A SINGULAR discovery has been made by accident in connection with some experiments upon cotton seed, which may have a widely extended influence upon agricultural operations. With a view to ascertain the situation of the oil-cells in the cotton seed, Professor Thomas Taylor, the microscopist was requested to make an investigation, and he found that one row of these cells constitutes a protection to the germinating point. The Professor resolved further to ascertain how far these defences protected the embryo from agents usually destructive of all organic life. In using sulphuric acid, he found that one result was completely to remove the adherent cotton, so leaving the brown shell of the seed clean, without being visibly affected. Some of the seed that had been thus treated was sown, and, to the surprise of every one, it came up at least five days earlier than the seed in its natural state. Several experiments were subsequently made, which confirmed the fact that the treatment with sulphuric acid stimulated the vitality of the seed. The gain of five or six days' start, in the avoidance of early frosts, or in the raising of early cotton, for which premiums are offered in some of the Southern States, cannot be over-estimated. Another advantage is that, owing to the cotton hitherto adherent to the seed, the sowing has had to be broadcast, which has been very wasteful. Now the clean seed can be sown by means of a drill, with the result of producing a regularity of growth which will tend greatly to facilitate the subsequent cultivation. The Americans are shrewd enough to apply this treatment with sulphuric acid to other seeds slow of germination. And we cannot but think that our English agriculturists will take advantage of this suggestion. If we have no seeds, like the palm, which take three years to sprout, at any rate there are frequently seasons when the power to hasten a natural operation will be an immense advantage.

THE seventh, part of Mr. Phillips Bevan's *Statistical Atlas*, just published by Messrs. Johnston, of Edinburgh and London, is devoted to the agriculture of the United Kingdom. It will probably surprise most persons to find that in England and Wales, where the *grande culture* is supposed to reign almost supreme, upwards of 346,000 out of the total of 473,638 holdings are of 50 acres each or under. The farms above 1,000 acres appear to number 506. In Scotland out of 80,101 holdings 55,280 are of 50 acres or under, and 79 only exceed 1,000.

THAT there is a decline in the production of wheat in England is only too apparent from the most recent returns. The following statements from the *Economist* show the outturn per acre to have fallen from 29·3 bushels in 1849-58 to 25·6 in 1869-78: "It is noticeable, in connection with this subject, that there has been of late years a decline in the yield of wheat in this country, which is the more remarkable, as during the same period there has been a contraction in the acreage under that crop. Presumably now, the better land is being retained for this purpose, and what is less fit for the growth of wheat is being employed in other ways. Hence an increase per acre, not a decline, might reasonably have been looked for. The figures as to the growth of wheat which we derive from the statement by Mr. Caird, and which are confirmed by other and equally unimpeachable testimony, are as follows:—

ESTIMATED PRODUCE OF WHEAT PER ACRE IN ENGLAND.

1849-58	29·3	bushels.
1859-68	29·1	"
1869-78	25·6	"

This may be compared with a similar estimate of the growth of wheat in France, which appeared a short time since in the *Journal des Economistes* of Paris:—

ESTIMATED PRODUCE OF WHEAT PER ACRE IN FRANCE.

1815-35	13 0	bushels.
1836-55	15·0	"
1856-76	16·4	"

The yield in France is still greatly below that of England, but it is remarkable that the movement should be upwards in the one case, and downwards in the other. A decline in the character of our agriculture is not a pleasant thing to contemplate, but we fear it is the probable explanation." Is this caused by the greater poverty of the farmers preventing them from cultivating their lands so thoroughly, or nourishing them so generously as they were wont to do? Whatever may be the cause, the result is clear, and while we are still a long way ahead of France and other European nations, it must not be forgotten that while our outturn is steadily decreasing, theirs is as steadily rising, and it may be only a question of time when we shall be absolutely behind other nations.

THE first administrators of the Punjab had the reputation of being the most able and interesting writers of reports in India; the works of their successors should be dedicated to the goddess of the Dunciad, "laborious, heavy, busy, bald, and blind." The revenue report of the Irrigation Department of that province for the year 1879-80 is no exception to this rule. Dulness is slow, and the report bears no date, the Chief Engineer possibly objecting to furnish evidence against himself, but the resolution upon it was written last March, almost a year after the period reviewed. The Chief Engineer attributes a decrease in the area irrigated to "the alteration in the land revenue settlement, which has induced people to try whether they can do without irrigation now that they only pay the owner's rates when they take the water." It was certainly a hardship when the owners had to pay for water whether they took it or not. And this is still the case to a great extent in the Punjab, where we see that eight lakhs of rupees were credited to canals as "increased land revenue," which will have to be paid as well by those who reject the water as by those who take it. As long as this is the case all irrigation accounts are deceptive. It cannot be said that the department *made* so much during the year, but that it realised so much in the way of taxation. We might as well talk of the profits of the Road Cess Department as of those of the Canal Department, where the rates are compulsory "Before the new settlement," says the Government resolution on the report, "the people were forced by the high rate of the land revenue assessment to take water, the land was over-cropped, swamping resulted from excessive irrigation, and the health of the people suffered." And yet the resolution expresses a hope that the irrigation of the abandoned area "will be renewed in due time." This suggests the question, what is the due time for over-cropping and swamping the land, and for injuring the health of the people. What is wanted in the Punjab irrigation system is the removal of the charge for irrigation in the land settlement, this amount being added to the rates, and the latter made really voluntary. The cultivators would not then have to pay for water whether they took it or not, and the temptation to saturate the country into a malaria bed would be diminished. We would also know, what we cannot know, whether irrigation in the Punjab really pays, apart from compulsory taxation.

OFFICIAL PAPERS.

TREATMENT OF FOOT AND MOUTH DISEASE IN HORNED CATTLE.

FROM A. MACKENZIE, ESQ., Secretary to the Government of Bengal, to all Commissioners of Divisions (except Bhagulpore),—Circular No. 1T, dated Darjeeling, the 15th July, 1881.

IN continuation of the Circular from the Revenue (Miscellaneous) Department of this Office, No. 4, dated the 15th May 1880, I am directed to forward, for your information, the accompanying copy of an endorsement* from the Commissioner of Bhagulpore, and of the enclosed report, giving particulars of the successful treatment, according to Mr. Stirling's method, by the Assistant Manager, Raj Durbhunga, of foot and mouth disease in horned cattle at Khurruckpore in the Monghyr district, and to request that the report may be circulated as widely as possible within your division.

*** No. 2279B, dated 28th June 1881.**

2. I am at the same time to ask whether you could not prevail upon some of the tea-planters or carrying companies in the Darjeeling district, where cattle-disease is always prevalent, to try Mr. Stirling's method of treatment. The Lieutenant-Governor is, I am to say, willing to sanction an expenditure of Rs. 200 if you could get some reliable persons to try the experiment. The Rev. Mr. Wilson might, I am to suggest, be asked to try it.

To Commissioner, Rajshahye and Cooch Behar Division only.

No. 2279R, dated Bhagulpore, the 28th June 1881. Memo. by G. N. BARLOW, ESQ., Commissioner of the Bhagulpore Division.

Copy forwarded to the Secretary to the Government of Bengal (Medical and Municipal Department), with reference to his No. 588 of the 29th ultimo.

From Baboo CHUNDER SIKHAR BOSE, Assistant Manager, Raj Durbhunga, to the Magistrate of Monghyr,—No. 685, dated Khurruckpore, the 16th June 1881.

With reference to your memorandum No. 268G, dated 14th instant, forwarding copies of correspondence noted on the margin, I have the honour to furnish as under, the information called for therein.

Officiating Secretary to Government of Bengal, to Commissioner, No. 588, dated 29th May 1881.

Commissioner's No. 2021R, dated 8th June 1881, to address of Collector of Monghyr.

(1) Thirty-one cows and bullocks were treated this year, from December 1880 to 18th February 1881, and all of them were cured with the medicines prescribed by Mr. Warren Stirling.

(2.) In all cases the sore between the claws was found to be sympathetic, as no instance was found in which the sore appeared in the feet unless there was the affection of the mouth.

(3) The disease appeared to be infectious. Immediately on the animal becoming affected, the affected beast appeared listless and disinclined to take food. Its head generally drooped, and frothy saliva flowed from the mouth.

(4) The sores on the feet in a few cases remained for about a week, even after the mouth had been healed.

(5.) The following medicines were used—

For the mouth—

Honey (brought from bazaar) ...	... 2	lbs.
Muriatic acid (supplied from the Durbhunga Raj dispensary at Khurruckpore	... 2½	oz.

mixed well in an earthen vessel (in want of a glass one) with a wooden rod, and applied with a jute brush about a dessert-spoonful to the tongue three or four times a day. For the feet—

Socotrine aloes (or raw musabbar brought from the bazaar)	... 4	oz.
Alum (bought from the bazaar) ...	... 1½	"
Mowah wine (rectified spirit not being available here) ...	... 12	"
Water (common) ...	... 24	"

The above medicine for the feet was prepared and administered as prescribed by Mr. W. Stirling.

(6) The diet allowed to the beast affected with the soreness of the mouth was rice boiled down to a thick *congee*, with a little sugarcane goor mixed with it.

(7) Whenever medicine was given, the nozzle and legs were washed with pure water only, carbolic acid not being procurable here nor in the Raj dispensary.

(8) The time taken for curing the mouth disease took from 10 to 12 days, and that of the foot about a week longer. With fresh and rectified European medicine, perhaps the disease would be cured within a shorter period.

Memo. by G. M. CURRIE, ESQ., Officiating Magistrate,—No. 281G, dated Monghyr, the 21st June 1881.

Copy forwarded to the Commissioner of Circuit, Bhagulpore, with reference to his No. 2021R—93RR of 8th instant.

Note by MR. WARREN STIRLING, Tea Planter, concerning the treatment of foot and mouth disease in horned cattle.

For the mouth—

Honey	... 1	lb.
Muriatic acid	... 1½	oz.

Mix well in an earthenware or glass vessel with a wooden or glass rod. Apply with a wooden spatula about a dessert-spoonful to the tongue, leaving the animal to distribute it over the inside of the mouth by the champing motion that is sure to follow its application.

In ordinary cases this should be administered twice a day, but in very severe cases, or should the beast have been affected some days before notice had been taken, three or four times daily will be requisite.

For the feet—

Socotrine aloes	... 1½	oz.
Rectified spirits of wine ...	... 4	"
Alum	... ½	"
Water	... 8	"
or		
Calvert's carbolic acid ...	... 4	"
Sweet oil	... 20	"

Dissolve the aloes in the spirit, and the alum (after powdering) in the water, and mix. Apply twice a day between the claws for mild cases, and three or four times for severe or neglected ones.

Suggestions as to the treatment, food, &c., &c.

Immediately upon a beast's becoming affected (which may be easily known by daily inspection when grazing or when fed in the stockyard, the affected beast appearing listless and disinclined to feed, head generally drooping, and a slightly frothy saliva flowing from the mouth it should be isolated from the herd, and treated at once.

The disease being very infectious, a close watch should be kept upon the remaining cattle for some days after the infected beasts have been detected.

A separate attendant should be deputed to attend upon the sick cattle, and must on no account be permitted to go near the remainder of the herd. As it would be impossible for him to administer the medicine without some of the beast's saliva (the virus of infection) falling about his clothes, he should be made to change them whenever he may have occasion to leave the hospital, and he should always wash his hands in some disinfecting fluid (a weak solution of *Calvert's* carbolic acid is the best). Care should also be taken to keep dogs away from the hospital as they moving amongst the litter, &c., would be likely to carry the infection to the stockyard.

From the soreness of its mouth the beast, however, much inclined will be unable to eat anything but the smoothest gruel or something of that nature. The best thing to give in India until the mouth become somewhat healed, is rice boiled down to a thick *congee* with a little goor mixed with it. No salt should be given on any account.

Water should be supplied freely as the beasts appear to suffer much from thirst.

Whenever medicine is given, the nozzle and legs should be washed with a weak solution of carbolic acid—one part of acid to twenty of water.

Should aloes and spirits of wine not be easily procurable, the sore on the feet should be treated with a mixture of one part of carbolic acid to five parts of sweet oil.

My experience leads me to believe that the sore between the claws is only sympathetic. Many cases occur, and some very severe ones, without any sores upon the feet; but in no instance does the sore appear on the feet unless accompanied with affection of the mouth. Moreover, the sores on the feet invariably disappear as the mouth heals.

After the disease has disappeared, all utensils, ropes, litter, &c., should be burnt on the site of the hospital, together with the materials of the shed or shut under which the cattle have been tethered, thus preventing infection, and also disinfecting the ground upon which the sick beasts have been stalled.

As everything used should be destroyed, only cheap vessels, such as common earthen pans, wooden buckets, &c., need be procured for hospital use.

RESOLUTION ON THE ANNUAL REPORT OF THE ROYAL BOTANICAL GARDEN, CALCUTTA, FOR 1880-81.

READ—The annual Report of the Royal Botanical Garden, Calcutta, for 1880 81.

Considerable progress was made during the year in the work of laying out the grounds, especially in the eastern part of the garden. An important improvement was also carried out by the excavation of a drainage channel along the northern boundary of the garden, which benefits not only the garden itself, but also the villages and fields outside, and has been adopted by the Public Works Department as part of a scheme for draining the grounds of the Sibpore Engineering College. The soil obtained in excavating this drain was utilized in raising the level of a large portion of the garden. Along part of the western boundary a similar drain, on a smaller scale, has been dug; but it requires to be extended, both for the protection of the garden, and in order to furnish material for raising the grounds where they are still swampy and unsightly. As it is very desirable that the improvements in the garden, which have been in progress for some years past, should be completed as quickly as possible, the Superintendent has since the close of the year, been allowed a supplementary grant to push on the work in the western part of the garden where much remains to be done.

2. Other improvements have been made during the year, such as the planting of new groups of trees, the re-laying of roads, and the erection of a glazed propagating-house, and and additional plan-shed. Dr. King further proposes to erect a steam-pump, similar to that in the Zoological Gardens, in order to keep the water in the garden tanks at a high level all the year round. To utilise the pump fully it will be necessary to connect the tanks by under ground pipes, and the Public Works Department are now preparing an estimate of the cost of the connections and of a suitable engine. As the boundary of the garden was in parts ill-defined. Dr. King has, in communication with the Magistrate of Howrah, caused a number of substantial stone pillars to be erected round the land boundary.

3. As noticed in previous reports, Dr. King does not think that the cultivation of *rhea* is likely to prove a commercial success in Bengal. The prizes offered for an efficient machine for cleaning the fibre, have hitherto failed to create much interest in the subject, and it is unlikely that zemindars and ryots will underake the cultivation of the plant, until there is a cheap and effective means of bringing it into a marketable condition.

4. During the year under review, Dr. King, in compliance with the wishes of Government, deputed the Curator of the garden to examine the grasses that grow on the banks of the Adjai and Damooda, as well as those on the Brahmaputra between Chilmari and Goalundo, with a view to test their capability of yielding a paper-fibre. On the banks of all the three rivers the prevailing grasses consists of the three species of *Saccharum*, known in the vernacular as *kashee*, *sara*, and *khurse*. Each of these grasses has a stout, hard stem, which is quite unsuitable for paper-making, and the cost of collection and freight of the leaves and the leaf sheaths, which are the only parts that can be utilised, would, it appears, be so high as to prevent their transport to Europe from being commercially successful. Further trials have been made with some of the wiry grasses from the Orissa coast as well as with the *Baobab* and *Malachra capitata*, but the result is not hopeful. Dr. King recommends that attention should be given to the utilisation of the plantain which so far as the manufacture of paper is concerned, promises to be the best of the fibre-producing plants in India. The

Lieutenant-Governor has already expressed his readiness to assist any mercantile firm or private persons wishing to try experiments with the plantain in the Chittagong Hill Tracts or elsewhere in Bengal, by supplying them with wild plantain stems free of cost at the outset of the experiment and afterwards at reasonable rates.

5. Of the economic plants, the *Ceara* rubber continues to grow vigorously and to give promise of success. *Para* rubber and the Madagascar rubber have entirely failed. The other exotic rubbers are very large trees or climbers, and though, as Dr. King states, the collection of rubber from them in their native forests when they have grown to maturity may be profitable, the cost of planting and protection for several years, until they come to maturity will probably prevent their cultivation in this country from becoming a success. Of the other economic plants, the mahogany and *guango* or rain-tree, appear to be the only exotic trees which grow well in Bengal, and for which there is a demand.

6. Very valuable contributions were received in the herbarium during the year from the Royal Garden at Kew, and from officers and gentlemen both in India and other countries. Among the chief contributors were Dr. Aitchison; Mr. C B. Clarke, of the Educational Service, Dr. Brandis, Inspector-General of Forests; Mr. Gamble, Conservator of Forests, Bengal; Dr. Wood, Superintendent of Vaccination, Darjeeling; Mr. Peppe of the Opium Department; Mr. Levinge, Secretary to Government in the Public Works Department; Colonel Beddome of the Madras Forest Department; Mr. Fisher, Professor in the School of Forestry at Dehra Doon; Mr. Lebeuf, a French Botanist, and Colonel Collet. The present herbarium is much too small for the collection to be properly arranged and exhibited, and is in other respects unsuited for the purpose for which it is used. Before the next rains set in the garden will, the Lieutenant-Governor hopes, be provided with a new herbarium on the general model of the one at Kew. Some modifications of the plan of the building at Kew will be necessary in order to adapt it to the Indian climate.

7. The interchange of plants and seeds went on actively during the year. Forty Wardian cases and 134 open boxes, containing altogether 8,305 plants, were received from different parts of the world. Sixty-five Wardian cases and 280 boxes of plants, besides many plants potted and packed in other ways, were issued, the aggregate of plants distributed being 17,270. One thousand two hundred and fifty-six packets of seeds were received, and 3,224 packets were issued. The chief donors of plants and seeds were Sir J. D. Hooker of the Royal Garden, Kew; Sir George McLeay; Dr. Treub, Director of the Botanic Garden, Java; Dr. Trimen, Director of the Botanic Garden, Ceylon; Mr. Duthie, Superintendent of the Botanic Garden, Saharunpore; Dr. Regel of the Imperial Garden, St. Petersburg; the Directors of the Botanic Gardens of Melbourne, George Town, Demerara, and Mauritius; the Secretaries of the Agricultural and Horticultural Societies of Calcutta and Madras; the Superintendents of the Public Gardens at Rangoon, Bangalore, and the Eden Gardens, Calcutta; Colonel Cadell, V.C., and Mr. E. H. Man, of the Andaman Islands.

8. The death of Mr. Scott, Curator of the Herbarium, referred to in the Government Resolution of the 21st August 1880, occurred during the year under review, and considerable difficulty was found in procuring a competent successor. Mr. Brace, the gentleman appointed by the Secretary of State to succeed Mr. Scott, took charge of his duties at the beginning of June last.

9. The chief improvement carried out in the Lloyd Botanical Garden at Darjeeling during the year was the erection of a handsome conservatory, which will afford accommodation for the growth of many plants hitherto unknown in the Eastern Himalayas. A house for the exhibition of plants for sale is also about to be erected. The nurseries are well stocked with plants, and a considerable number were distributed in the past year to the Forest Department, and both gratuitously and by sale to the public.

10. The thanks of Government are due to Dr. King and his staff for their efficient management of their charge.

SILK IN THE PUNJAB.

From W. M. Young, Esq., Secretary to Government, Punjab, to the Secretary to the Financial Commissioner, Punjab, No. 760, dated Lahore, 12th July 1881.

I am desired to acknowledge the receipt of your No. 653, of 28th June submitting, for the information of Government, a report on the exhibition of silk cocoons held at Madhopore on May 2nd.

2. This was the first joint exhibition held for the rearers of silkworms in the Kangra and Gurdaspur districts, and under the rules which were laid down on the subject last year. The Lieutenant-Governor observes with pleasure that the exhibition was a great success, but in comparing the numbers of exhibitors with those of last year it is necessary to take into account the two separate exhibitions held at Gurdaspur and Nurpur. The number of exhibitors in the two districts in 1880 was 343, and the number in the present year was 417, showing an increase of almost exactly one-third. But for the fact that all the intending exhibitors were not acquainted with the rule that it was necessary for them to register their names as *bonâ fide* breeders, the number would no doubt have been still larger, and it may be hoped that there will now be a steady increase from year to year until the industry, at present in its infancy, really attains considerable proportions.

3. The cocoons from imported seed are said by the manager of Messrs. Listers' filature to have been as fine as any in the world. This is an extremely satisfactory result, and one that the Lieutenant-Governor hopes will be maintained. It is to be regretted that the country seed should have become generally diseased, but his Honor does not think that it is necessary to take any special steps in this matter, as proposed by the Financial Commissioner and the Commissioner. From the facts stated by the Deputy Commissioner that very few country cocoons were exhibited this year, and that Messrs. Lister gratuitously distributed foreign seed to all breeders who agree to sell the produce to them, it appears certain that the foreign seed will supersede the country seed without any effort being made in this behalf. It is not likely that this moths and worms of the two classes are allowed to mix, but unless the is the case, the infection cannot spread.

4. The return attached to the Deputy Commissioner's report shows that the produce of 2 maunds 26½ seers of seed was 347 maunds, 2 seers of cocoons. The rough outturn of silk is put at 80¼ maunds, but at the rate used by the Deputy Commissioner, *viz.*, 10·41 seers of silk per maund of cocoons, the amount would appear to be 90 maunds 12 seers. This seems to be a satisfactory result, but it is not possible to compare the figures with those of previous years, as the former statistics of one or the other of the districts are always incomplete in some particular. The Lieutenant-Governor trusts that this information will be carefully recorded in the future, and an effort should be made to gauge roughly the proportion which the cocoons exhibited bear to the whole number produced in the two districts.

5. The development of mulberry plantations during the past year has been satisfactory The Irrigation Department has been addressed as suggested by the Financial Commissioner, and requested to plant mulberry trees as far as possible on the banks of the Bari Doab canal and its main distributaries in the Gurdaspur district.

6. With reference to the proposal made by the Deputy Commissioner that the prizes offered by Government should be limited to the same amount as those offered in cash by Messrs. Lister, the Lieutenant-Governor agrees with the view of Colonel MacMahon and the Financial Commissioner for the reason given. The contribution to prizes made by the Kangra district was almost exactly in the proportion of the number of Kangra exhibitors to the whole.

7. The success of the exhibition was due in a large degree to the efforts of the Deputy Commissioner and of the gentlemen associated with him in its management, and the Lieutenant-Governor desires that his acknowledgments for their services in connection with it may be conveyed to them.

EXHIBITION OF SILK COCOONS.

From Colonel C. A. McMahon, Commissioner and Superintendent, Amritsar division, to the Secretary to Financial Commissioner, Punjab,—No. 1717, dated Dalhousie, 7th June 1881.

Exhibition of silk cocoons.

I have the honor to submit in original report No. 172, of the 31st May, from the Deputy Commissioner, Gurdaspur, on the exhibition of cocoons, held at Madhopur on the 2nd of May.

2. The exhibition appears to have been a very successful one, and the steady rise in the number of exhibitors, from 98 in 1876, to 447 in 1881, indicates, I trust, "that the silk industry has taken firm root in the district."

3. It is a gratifying fact that 131 of the exhibitors were zemindars. The work of rearing silkworms seems so suited for women and children, and it occupies their attention for so short a portion of the year, that I trust it will become more and more attractive to the agricultural classes of the sub-mountain districts.

4. It will be interesting to learn the result of Messrs. Lister and Co's experiment of hatching the eggs of the silkworm during the rainy season; and the Deputy Commissioner will be asked to notice this point in his future reports. I should think there is every hope of the ultimate success of the experiment, if it is persevered in for a sufficient time, and is combined with the selection of autumn laid eggs from year to year.

5. The country cocoons exhibited, appear to have been scanty in number and poor in quality. The reason assigned is that the country worms have become diseased owing to the importation of diseased eggs by the late Mr. Halsey. If this be so, it seems to me a question whether what remains of the country stock should not be bought up and destroyed. If this is not done, I should fear that the newly imported foreign stock will sooner or later become infected.

6. I do not concur with the Deputy Commissioner's suggestion, that in future the liberal contributions towards prizes, made by the District Committee, should be withheld, unless Messrs. Lister and Co. agree to contribute a sum equal to that paid by the Committee.

7. An English private firm must have large demands on their resources on the first establishment of a new enterprize in India; and I observe that, in addition to their contribution of Rs. 300 to the Prize Fund, Messrs. Lister and Co. also "awarded four handsome silver medals" which were "highly appreciated by the recipients."

8. If Messrs. Lister and Co. agree to raise their annual contribution well and good, but if they do not agree to do so. the District Committee could hardly expend the money at their disposal in a better way than by continuing to give an impetus to the silk industry of their district. It seems to me a promising enterprize and capable of great development. it would be a pity to throw a damper on its extension.

From Colonel F. J. Miller, Deputy Commissioner, Gurdaspur, to the Commissioner and Superintendent, Amritsar division,—No. 172, dated Gurdaspur, 31st May 1881.

I have the honor to report on the exhibition of cocoons held this year under the orders of Government, at Madhopur on the 2nd May 1881. Due notice had been given throughout this and the Kangra district, and lists of *bonâ fide* rearers were obtained from tahsildars, and copy submitted to Messrs. Lister and Co.

2. The Gurdaspur district Fund contributed Rs. 1,000, the Kangra district Rs. 300, and Messrs. Lister & Co. Rs. 300 for prizes. Messrs. Lister and Co also awarded 4 handsome silver medals, 2 for Kangra and 2 for Gurdaspur, to the exhibitor of the best cocoons by agriculturist and

professionals, and these medals were highly appreciated by the recipients; a large number of persons from all parts of the country assembled to witness the exhibition.

The following Committee awarded prizes—Mr. Moore, of the firm of Messrs. Lister and Co., who is a first-rate judge of the quality of cocoons; Mr. Chapman, Manager, Punjab Sugarworks; Lala Sanjhi Mal, Extra Assistant Commissioner; and the Deputy Commissioner, as President.

The prizes were awarded on the same principles and in the same way as last year; professionals and zemindars being separately classed, and cocoons reared from foreign and country seed being distinguished. Due regard was also had to the fact that the Kangra district only contributed Rs. 800, while Gurdaspur gave Rs. 1,000. The exhibition was held in the old Madhopur workshops, the cocoons being arranged in baskets in a large shed, the floor of which was nearly covered. A number of persons brought in cocoons, whose names had not been entered as *bonâ fide* rearers; those to whom the tahsildars, who were present, could certify, were admitted to the competition, and the other excluded; the reason being that in former years a *bonâ fide* rearer made over a number of cocoons to other parties who had not reared them, on the understanding that the prizes, if obtained, should be divided, and it was to prevent this that lists were prepared.

3. The examination of the cocoons occupied the greater part of the day, and it was quite dark before the last prize was given.

The subjoined table shows the result as compared with the previous years, and the result, I think, shows that the silk industry has taken firm root in the district.

1876.	1877.	1878.	1879.	1880.	1881.
98 exhibitors.	56 zemindars.	Not stated.	No exhibitions	63 zemindars.	124 zemindars.
	108 mixed people.			166 other professions.	323 mixed professions.
	164 exhibitors.			229 exhibitors.	447 exhibitors.

The last exhibition at which I was present, was that of 1878; when almost all the cocoons were from country seed. This year there were few of this description, the majority being from seed imported from Japan, France, and Italy.

4. The cocoons raised from the climatized Japan and foreign eggs were very good, and declared by Mr. Moore, the only expert present, to be equal to any he had ever seen. The country cocoons exhibited were, however, not of a very superior description; they were at the same kind as shown last year. The quantity was certainly much smaller; this is owing to a disease having infected the country worms for the last three or four years, and consequently very little seed was left in the district. This year also in a few places the worms have died. From inquires made by the agent of Messrs. Lister and Co., it appears that the disease was brought into the district by eggs imported by the late Dr. Halsey: these were hybridised with the country cocoons, which naturally spread the disease over the whole district; no remedy has yet been discovered, but it is said that the worms recovered by removal to a clear place.

5. The Rev. Mr Bearing sent out some from France to the Mission School, and some of the Christians of that mission exhibited as *bonâ fide* rearers. Mr. Keighley, manager of Messrs. Lister and Co., imported in large quantity, which was freely distributed to all requiring it.

He placed a portion of the buildings at my disposal for the accommodation of visitors and exhibitors, and the tahsildars arranged for food, &c. All the natives appeared much pleased and took a general interest in all the proceedings: next year Messrs. Lister and Co. hope to have seed available for distribution by 15th January, so that the worms may commence spring early in the season, and they intend to extend their mulberry plantations, not only at Gulpur but wherever land can be procured. They are about to build sheds at Gulpur and to make them over with a portion of the mulberry plantation to any person who will commence operations on the spot; their object being, of course, to obtain as many cocoons as they can, so as to keep the filature at work. The majority of the exhibitors sell their cocoons to the firm, and all who do so, of course prefer Madhopur as the place of exhibition, as it saves them a double journey. Those who reel their own silk prefer Gurdaspur, but I think Madhopur is the most convenient place, as regards accommodation, &c.

6. Only dead or dried cocoons were exhibited, a few of the tasser-silk cocoons were exhibited; but Messrs. Lister and Co. say it does not pay them to reel this silk, as the operation is troublesome and unremunerative. Messrs. Lister and Co. are about to try the experiment of hatching eggs of silkworm during the rains; they are taking all the seed to Dalhousie for the summer, and will bring down a certain quantity in July for distribution, and will give 4 silver medals for the best cocoons then produced; they seem confident about their success but the native professionals are not of the same opinion.

* * * * * *

8. The information regarding the necessity for feeding silkworms by night as well as by day was properly made known to the people. Zemindars take this silk culture up because their wives and children can work at it while they are in the fields, but the professionals make it their principal business, and are able to devote more time and attention to the worms, both at the breeding and spinning stage than a zemindar who comes home wearied by his out-door work can possibly do, and this is why professionals are most successful in sericulture.

9. I think for the future, Messrs. Lister & Co. ought certainly to contribute a sum equal to that given by the District Committee of this and the Kangra district for prizes, and I would propose next year to withhold the sanctioned amount unless they agree to this.

10. I beg to submit a statement showing the operations of the years in planting and developing mulberry trees.

11. Messrs. Moore, Chapman, and Lala Sanjhi Mal, Extra Assistant Commissioner, are entitled to my best thanks for all the trouble they took in selecting the best cocoons for prizes, no easy task where so many had, to be inspected, I could give them but little assistance in this respect. Mr. Keighley, the manager of Messrs. Lister and Co's firm at Madhopur, was most kind and courteous to all natives and Europeans attending the exhibition, which was I consider a great success. Poor old Jafir, who was the first to introduce sericulture into this district, is dead, but his family continue the business, although owing to dispute it has fallen off.

REANA LUXURIANS.

From W. M. Young, Esq., Secretary to Government Punjab, to the Joint-Secretary to Government, Punjab, Public Works Department Irrigation Branch, No. 777, dated Lahore, 16th July 1881.

I am desired to acknowledge the receipt of your No. 2350, of 24th June last, submitting reports as to the cultivation of the *Reana luxurians* during the year 1880.

2. Although in some places the attempt to cultivate the crop proved a failure, and it cannot be said that it has yet been found to be a success in India, still in view of the results obtained at Gungatoli in the Delhi Division, and on the Upper Sutlej Canals, the Lieutenant-Governor is not willing that the experiment should be entirely abandoned. The yield per acre of the crop sown in the former case amounted to 691 maunds of fodder and 4½ maunds of seed, and in the latter to 737 maunds of fodder and 12½ maunds of seed. These results are much better than any reported at the Cawnpore Farm in the North-Western Provinces, and the Lieutenant-Governor would wish to see a systematic attempt made to grow the *Reana luxurians* for two or three years before the experiment is given up.

3. It does not appear certain that the officers conducting the experiments understand that the chief object of the crop is to obtain a plentiful supply of fodder, and it would seem that if the same procedure were followed in the case of each experiment, there would be reason to hope for good results in almost all cases. I am accordingly to request that the following instructions may be issued to the officers concerned, and that they may be directed to carry them out carefully. As it will be impossible for the orders to have effect from the present season, it will be necessary to postpone their adoption till 1882; from the results which may be obtained in that and the following year, it may be hoped that it will be possible for the Lieutenant-Governor to decide whether the experiment should be continued or not.

4. The *Reana luxurians* should be sown in the end of March or beginning of April, in ground which has been well prepared and manured, and which is capable of irrigation as may be required from time to time. The seed may either be planted in rows, each seed being placed at a distance of one yard from the others; or in a nursery, from which the young plants may be moved when 5 to 6 inches high, and planted out at intervals of one yard from each other. The crop should be watered as many times as may be necessary, and when the plants have attained a height of 4½ to 5½ feet, they should be cut down 2 or 3 times, as may seem best, to a height of 1 foot; after the 2nd or 3rd cutting they should be allowed to come to seed. An exact record should be kept of (1) the area sown; (2) the amount of, and quantity of seed used, and manure given to the land; (3) the number of times the land was ploughed and watered; and 4 the amount of fodder obtained at each cutting and the yield of grain. Neighbouring villagers and rural notables should be invited to come and see the crop, and the green fodder can be given to agriculturists to allow them to see if it is relished by their cattle. In reporting the results, the outturn of the actual area under the crop and the estimated outturn per acre should in all cases be stated.

5. It is true that the cultivation of the *Reana luxurians* is more costly and lengthy than that of *chari*, but under favorable conditions the yield is very much larger; and though it does not appear to be relished as a dry fodder, it would seem possible to provide a valuable store of green food. The Lieutenant-Governor would therefore wish to see the experiment as above indicated carried out for two years, in order that the real merits of the crop as a fodder one may be fairly tested.

AGRICULTURAL SHOW IN KATTIAWAR.

Letter from Major Henry Lowther Nutt, Assistant Political Agent in charge Jhalavad Praut, to Colonel L. C. Barton, Political Agent, Kattiawar, Political Department, No. 765, dated Wadhwan Civil Station, 4th February 1881.

I have the honor to state that an agricultural show and cattle fair were held in this place on the 10th, 11th, and 12th instant.

2. This is now the third time that a meeting of this description has taken place here, the two former ones having been held in 1872 and 1873.

* * * * * * * *

9. I attach an interesting report by Mr. Lamb, Inspecting Veterinary Surgeon of this presidency (who was specially deputed by

Government to attend the show) on the animals exhibited in Class I, *viz.* :—

Arab stallions	... 2 exhibited	... 2 prizes.

„ geldings	... 1 „	... 1 „	11 mixed breed, 2 prizes.
„ colts	... 18 „	... 4 „	
„ fillies	... 14 „	... 0 „	
„ ponies	... 0 „	... 0 „	
Ponies of any other breed and Savars' horses	... 10 „	... 5 „	

10. Upwards of 250 animals were shown in this class, and it was highly satisfactory to see that the famous old indigenous breed of Kattiawari horses is not "on the wane," but likely, if treated judiciously, to maintain its original high repute, and yield many a valuable remount for our Native Cavalry in addition to furnishing the ordinary requirements of the Chiefs and others.

11. The Katty stallions which took the 2nd prize, and is described by Mr. Lamb as in some points even superior to the well-known "Redo," was discovered by me about a month ago in a village in this neighbourhood. He is a son of Redo's, is 5 years old, and is quite sound. He stands 14-2, is a bright dun with a dark list along the spine with bars on the forearms (the old Katty colour), and is a truly grand looking animal, full of fire and life, with good bone and substance. He was for sale, and I immediately purchased him for one of the States under my supervision.

12. The show of cattle in Class II. was exceptionally fine. Some very valuable bulls, cows, oxen, and buffaloes being exhibited by many of the Darbars, first prizes being taken by his Highness the Thakore Saheb of Bhavnagar, the Thakore Saheb of Palitana, the Thakore Saheb of Wadhwan, his Highness the Raj Saheb of Dhrangadra, and the Thakore Saheb of Morvi.

13. Class III., which included sheep and goats, was well represented.

14. The camels in Class IV. were much admired.

15. In Class V., which was for asses and mules, there was not a single mule shown, and only a few small asses which were undeserving of prizes. It is strange but true that there exists a strong feeling amongst the people in this part of the world against breeding mules. It is looked upon by some as disgraceful, by others as laughable, &c., &c., and when Class V. was discussed in meetings of the Working Committee, all seemed to dislike talking about either asses or mules. Any native gentleman would have regarded it as insulting to have been appointed judge of the class.

16. The show of poultry was fair. It is the first time that fowls have been exhibited here, and it was not to be expected that there would be anything very wonderful. Next year I hope it will be different.

17. The fruits, vegetables, and grain were excellent. It is very encouraging to observe how greatly the practice of growing certain wholesome English vegetables, which appear well suited to this climate and liked by the people, has increased of late years. No Darbar of any pretensions is now without its gardens in which are found cabbages, cauliflowers, nolkohl, beetroot, lettuce, &c., &c., and some very good collections of such vegetables were sent in from all quarters those from Bhavnagar being particularly fine.

18. The remaining class which included oil-seeds, fibres, cotton, tobacco grown in India, dyes, forage plants, and grasses, miscellaneous articles and machinery and implements, were one and all very fairly represented. It would have been more satisfactory if there had been a greater display of machinery, as many of the Chiefs are becoming keenly alive to the advantages to be derived from machinery in simple form, which economises hand labour or reduces expenditure. A few good pumps, for instance, would have been bought up at once if of moderate cost; but sellers in Bombay are backward in sending what they have up-country at the risk of no sale. An elaborate astronomical clock made by Joshi Shankleshwar of Ahmedabad, by direction of the Dhrangadra Darbar, was much admired.

* * * * * * *

20. The ploughing matches, which took place in the early morning of the third day, were a great success, and were witnessed by thousands with much interest. A capital place was found for both workers and spectators. On the bank of a canal adjoining the show yard, the people gathered in vast crowds, seats being placed in a good position for Chiefs and English ladies. The plots to be ploughed—each plot measuring 8 guntas, or 1/5 of an acre—were marked out with small flags, and each plough was placed in position in right-hand corner of its particular plot. When the gong sounded, the bullocks were yoked and all stood ready for action. At the next sounding all started of simultaneously, and continued ploughing for 30 minutes, the judges being present throughout to see that all was done correctly. At the third sounding of the gong all stopped immediately, the bullocks were unyoked, and the judges then commenced their work of judging, giving points for—

1st, amount of land ploughed.
2nd, depth of furrow
3rd, direction of furrow.

These matches created much excitement amongst the Patels and experienced ryots who were present in great numbers, having been given special leave by their respective Chiefs to attend the show and watch the proceedings; and it was a most exhilarating sight to see the skill and energy displayed by the ploughmen, the land when ploughed, bearing testimony to the fact that good work can be done by the ordinary native ploughs, provided they are drawn by strong bullocks and guided by intelligent, vigorous men.

* * * * * * *

26. In conclusion I would beg leave to say that after many years' experience of these agricultural meetings and shows, I am convinced that, if carefully conducted, they are quite in accord with the feelings of the people, high and low. The interest shown was quite genuine; the exertions made were prompted by a healthy, natural liking for the cause generally; and no fear need be felt that agricultural progress in this part of Kattiawar will languish, if the subject is kept prominently forward in a popular form. By degrees these undertakings will assume a more practical shape, I most firmly believe; at the same time it is necessary to understand that the Indian people have vivid imaginations which would not be favourably impressed by the dull proceedings of an ordinary sale of cattle. The Chiefs would not care for such things, and at the present stage of affairs in Native States, we cannot afford to lose their assistance; for, as already stated, it has been principally owing to their hearty co-operation that the show, now reported on, has been enjoyed by so many.

Now that this Wadhwan agricultural meeting has been revived, it is to be hoped it will be continued annually. All who were present promised their future support; and as in due course of time intelligence spreads with reference to place and time of holding, it will become a recognised institution in this part of the country. Trusting that these proceedings may meet with approval.

SELECTIONS.

THE DEFECTS OF INDIAN AGRICULTURE.

NOW that the Government of India are devoting some attention to the subject of agriculture in India, and interest in the same is being also evinced by people at Home, it would not be out of place to call attention to some of the defects in our mode of agriculture. In a paper contributed by Mr. Gogendra Narayan of Kuch Behar to the National Indian Association Journal, he deals exhaustively with the subject, and offers suggestion for the remedy of the state of things now existing. Agriculture is the chief industry of India and that on which the Indians live. There is no other industry worth speaking of at present. A few miles have been established for the spinning of cotton, &c., but the number of operatives employed by them is but an infinitisimal portion of the population. Gold Mining is still in its infancy and may if it prove successfully, be one of our chief industries providing employment to a large number of people, but it is to be regretted that the movement at present interferes seriously with agricultural pursuits, and we hear complaints from Wynaad that the coffee industry is being neglected. Agriculture therefore being the sole industry, which is to maintain an average population of 212 persons to the square mile, the improvement of that industry ought to be prominent above all other considerations. In speaking of the people who form the agricultural community of India, the writer says, that they are poor in capital, generally uneducated, ignorant of the practice of other countries, and consequently without the knowledge of improvements which might well be adopted. It is next to impossible to advise them to do a thing in a different way to that which they have been accustomed to do. The ryot should be shown by experiments that a certain thing can be done in a certain way far superior in every respect to his own. The system of ploughing followed by the Indian ryot is far from perfect. The instrument itself, is very deficient in working, and the soil is merely stirred not ploughed. It is then left for a few days when the sun dries up the clods, after which they are broken with a wooden mallet. The weeds are collected, burnt, and the ash spread over the soil. In 98 cases out of 100, it is the sole manure applied to the land. When the land is ready the seeds are sown and left to Nature's care. The harvest time comes and the crop is cut down with a sickle, a very light instrument which does the work slowly. The sheaves are stacked round a tall tree, and when the weather is favorable they are taken out, laid on a firm circular piece of ground and trodden either by bullocks or men. There is always a great loss in this operation, as a considerable quantity of the grain sticks into the ground and it would not pay to dig it out. The winnowing process is also a very primitive one and the produce is at length ready for the market whither it is conveyed, whenever convenient and sold. The Indian ryot is quite oblivious of the evil result of the continuous growth of the same crop year after year. The idea never enters his head that the soil is apt to get exhausted, and requires to be nourished. Under the present exhausting system the land is being slowly deprived of the elements of plant food, and if it be not checked and some new system introduced, which will restore to the soil its exhausted fertility, the Indian soil must as a matter of course, become unfruitful. The exhaustion of the soil is one of the chief sources of Indian famines. This exhaustiveness of the Indian system of husbandry has been shown experimentally. In this presidency, in places where they used to grow fine tobacco some years ago, are quite barren now, and will not produce the crop. Tobacco is one of the most exhausting crops, and carbonate of potash is one of its chief elements of food; consequently when tobacco is grown year after year in the same land, of course, the land will lose this important element, some of the Madras tobacco soils have been analysed and found to be in want of carbonate of potash. In the North-West Provinces, it is said that wheat-land, which during Akbar's time yielded 1,140lbs. to the acre, now only gives 840lbs. and the same description of land in some of the Eastern countries of England is made to yield 1,800lbs. The chief crops grown in India are rice, potatoes, tobacco, maize, wheat, barley, &c., apple, grape, and other articles of luxury are also grown. In Southern India tobacco is grown extensively, and there are also coffee plantation

chiefly belonging to English cultivators. Various experiments have been tried by the Madras Government on the growth of exotic tobacco, but they have as yet not been successful. The suggestions made for improving the agriculture of the country is as follow, and they merit the attention of the new department just established.

1. The establishment of Agricultural Societies for the general improvement of agriculture and the agriculturist. These institutions, must be in various districts, because of the variations in climate, soil, and produce, and they must co-operate with one another. These societies ought to start with breeding of stock, trials, and introduction of seeds and improved implements, encouraging agricultural education, introduction of local rotation of crops and holding of annual shows for agricultural produce. The Indian Government ought to help the societies by providing them with seeds from other countries, giving full consideration to any suggestion which the societies may make as to land tax, or any other thing concerning the ryot, extensive irrigation works, and less irrigation rates on forage crops, which will enable the cultivator to keep a certain number of stock, and consequently to procure manure for his land, elements of agricultural education to be taught on the village schools. Landlords ought to take more lively interest in their land and ought to spend more money on its improvement than they have hitherto done. They ought to introduce new implements, seeds, and improved breeds of stock. Forest conservancy is also a matter to which attention should be given in connection with improved agriculture. The moisture of the land will be thus reserved and the underwood could be used as fuel, thus utilising the dung for manuring purposes. Madras Government has been trying several experiments for the last ten or twelve years at the experimental farm at Saidapet and is doing some very important work, little appreciated by the ryots, because of his inability to do so. If the Native States follow the good example set by the Madras Government, a vast deal of knowledge will be imparted to the agricultural population, the salutary effects of which will soon be perceptible. Too much importance can not be placed on the necessity for improving our cattle by the introduction of a better class of breeding stock, of course, attention should be paid to the description of food given to them. The custom in force, says a contemporary is to allow these unfortunate animals to eat what ever may not happen to be of any value, and they are generally supposed to pick up their living as they can. Crops are never grown with a view to provide cattle food. At home this is an important item of a farmer's duty "to see to the providing of a plentiful supply of nourishing food for his cattle." It will be seen from the foregoing remarks, that the Indian cultivator has much to learn in regard to his occupation of tilling the soil, and it will be as much for the interest of the Government as of the ryot to initiate measures whereby the needed instruction can be given.—*Madras Athenæum.*

COCOANUT CULTIVATION.

Of late years very little attention is given to cocoanut cultivation in this city and its suburbs, though at one time—and this was not many years ago—owners of land, natives especially, emulated each other in forming large and well-stocked cocoanut plantations. Cocoanut cultivation is by no means an unremunerative business. In the northern and southern parts of Madras, from Royapooram to the village of Trivattoor and between St. Thome and Adyar and further south, cocoanut trees may be seen planted in admired confusion. It was once considered a grand thing for at moderately well-to-do Hindu, official or non-official, to possess a well stocked garden of cocoanut trees either at Washermanpettah, on the Trivatoor High-road and other places, and those who had no desire to enter into trade or public employ were content to be owners of small gardens on the produce of which they subsisted. But these things have now changed. To own a small plantation is considered somewhat *infra dig.*: to pass the matriculation examination, to enter the Government service, to be a subordinate in a public office, to be a prominent member of a reading or debating society are considered worthy the ambition of the members of the rising Hindu generation, while a very lucrative business is being gradually neglected. The effect of this indifference will not be felt now. Ten or twenty years hence when the plantations now in full working shall be no more, the want of the cocoanut tree will be felt, and then we may look forward to the revival of a branch of industry that is just now neglected.

Many years ago, when people were anxious to do something, whereby their names may be perpetuated, or when they wished to endow a public institution—be it educational, ecclesiastical, or charitable—they generally made over lands for the support of the institutions, and such lands were invariably planted with cocoanut trees, the revenues from which went to the support of the institution or charity. We see this especially in connection with Roman Catholic and Hindu endowments. The revenue from these plantations during certain seasons is fairly good and well able to support small charities. Some years ago when Lord Napier was Governor of Madras, he hit upon the idea of planting the grounds attached to the Gordon Refuge in St. Thome with cocoanut trees in the hope that revenue will in time be derived from this source for the support of the institution. A fine cocoanut tope has been formed alongside that useful institution but, strange to say, that although ten or more years have passed since the trees were planted, they have neither produced cocoanuts nor toddy. Few products of the vegetable world are adapted for so many useful and divers purposes for the convenience of man as the cocoanut tree. It may be mentioned that the Laccadive islands produce a very large supply of cocoanuts, and that the islanders barter the valuable produce of their trees for blue cloth, old guns, knives, &c., which they very much prize. The revenues of the Government are to a certain extent, dependent on the extension of cocoanut planting. Every cocoanut tree that produces toddy for the time is the property of the Government. The Abkarry Department takes charge of and marks the tree and the Abkarry contractor of the district or village is bound to draw toddy from the tree and pay the owner a stipulated rate for the juice he extracts. The toddy contract of a large city like Madras brings in some thousands of rupees a year and in some of the mofussil districts the revenue is much larger. The contractor undertakes to draw and sell toddy in so many shops in a village or taluq of the district which he has purchased, and he has to carry out the terms of his contract very rigidly, failing which he lays himself upon to severe penalties.

We have alluded to some of the advantages to be derived from the cultivation of the cocoanut and of the condition of some of the plantations in northern and southern parts of the town. It is evident that interest in this valuable branch of agricultural industry is on the wane. While the Government are giving attention to other matters connected with the agriculture, it may not be undesirable to give some little consideration to cocoanut plantations from which the public revenues derive a not insignificant portion of their income. The Abkarry Department will not, ten or fifteen years hence, be able in Madras to show such a large income from the toddy contract as is now done owing to the fact that cocoanut plantations do not receive the same attention from private person as they used to do. The Government of Ceylon, we observe, is giving some attention to this matter, and European planters have entered a field which was hitherto left altogether to Hindu enterprise. In Jaffna cocoanut cultivation a few years ago was considered very unremunerative and few European planters cared to venture in a speculation which they all along thought would not turn out well. But they have found out their mistake. One or two experiments lately tried have proved so successful that they have been encouraged to farther efforts, and plantations which two or three years ago would have been willingly sold for the value of the land are at present held for much higher prices. What has been achieved in Ceylon may be easily attained in Madras, and it is left to those who have the will and the means to make an effort and with the countenance of the Government, a valuable agricultural industry may be successfully worked.—*Madras Standard.*

AGRICULTURAL SPECULATIONS IN INDIA.

There appears to be some difference of opinion regarding the capabilities of Tripasore as an agricultural arena for Eurasian enterprise. A correspondent writing to us from Tripasore a short time ago, spoke of the difficulties attendant upon agricultural enterprise in that direction, and said, what we believe to be the fact, that any stranger attempting to cultivate land there would meet with the most vexatious and even ruinous opposition from the ryots and zemindars around. Mr. White, however, is of a different opinion, for he said at the meeting of the Eurasian and Anglo-Indian Association, last Friday evening, that "it was intended to divide the land of the Association at Tripasore into plots and allow people of means to build cottages and open out farms, and by doing so they would become land-owners and *extirpate the zemindars.*" We rather think not. The zemindar is a person that will take a very great deal of extirpation indeed, and a good deal more than the Association can put upon him. It is, in fact, the zemindar who is the great obstructive of any kind of agricultural innovation in this country, and we have heard of two remarkable instances in which he conquered and routed English interlopers, though these were able to invest a considerable amount of capital in their adventures. In one case, a gentleman from Australia tried to start a stud on his own account. He took a lease of land, and he purchased mares and stallions and built all the necessary offices; but he could not carry out his speculation for the opposition of the natives around. They quarrelled, and he left India a sadder and a wiser man. In another case, an Englishman who had been much taken with Colonel Greenaway's little book on "Farming on the Indian Plains," invested some money in wet and dry land, bought bullocks, the best seeds, and farming implements, but only to lose all. From the very offset the zemindars, his neighbours, were opposed to the intrusion, and they quickly made it too hot for him to stay.

As the law stands, it would be simply waste of time and money to try to get the better of these obstructives by litigation. Before Englishmen, or Eurasians, can ever hope to enter into agricultural competition with the native on his own ground, the law would have to be changed, and in such a way as would upset all economies. Moreover, competition of the kind is on the face of it, impossible. The native will always undersell his more luxurious competitors. He is content to live on next to nothing—a handful of grain,—and to dwell in a hut of mud and leaves. He will work from sunrise to sunset to screw a few annas more out of the soil, and he is a member of a great family of rustics who are ten times more conservative in their opinions, and a hundred times more prejudiced in their views, than even is the English farmer himself. To fight such a man on his own ground, where he has the control of the local labor and of the tongues of the villagers, to say nothing of his caste influences to back him, is only to run one's head against a stone-wall. The only possible way of getting the better of zemindars and ryots would be for some one to farm upon an

immense scale, and with a vast amount of capital. But would the game be worth the candle even then? That is a question. The Anglo-Indian Association Colony, which is a colony on small scale, with insufficient capital, is, we fear, not likely to do much good at Tripasore or elsewhere. That is to say if the colony is to be self-supporting.

Of course, if a number of persons, each one with an assured income,—or "means," as Mr. White puts it,—associate together to live in a square, or a row, or a street, there is no reason why their adventure should not be as successful at Tripasore as it would be in Madras. But *cui bono*? Unless it is the very problematical extirpation of the zemindar. To make such a colony pay out of wet or dry cultivation while there were natives about, would, we think, be quite impracticable. And by this is meant rice and the ordinary crops of this part of India, but not market gardening, which is another thing altogether. It is very possible that if a small number of Eurasians were to take up a suitable piece of land, not too large, and were to work it industriously with the spade, just as Chinamen work their market gardens in the Flowery Land, the thing would pay; for they have Madras as a market, and the natives are themselves slothful and careless in their market-gardening; but the labor would be hard, and the profits inconsiderable to a Eurasian or Anglo-Indian, though they might appear sufficient to the parsimonious Chinaman or to the native of India. This is, however, the only prospect that we see of the poorer Eurasians being ever able to make anything out of the land as cultivators of it. Fruits and vegetables grown on the Chinese economical system is small terraced plots, and with plenty of manure and water, is the Eurasian cultivator's best chance, and if he were to add to this industry, with his wife's and children's assistance, the breeding of a decent kind of poultry,—something better than is commonly sold,—and the production of cleanly-fed pork, he might very probably earn something better than a mere livelihood. It is very doubtful, however, whether Eurasians will ever take kindly to a country life, and to rural occupations. They are for the most part born and bred in cities, and their ways are the ways of the city, not of the country.

Mr. White says that "our late Governor believed in the land scheme" but that was, we fancy, because our late Governor knew nothing of the opposition which the natives can always enter against European or Eurasian intruders. In the little book on Indian farming above referred to, nothing seems simpler than to rent so many hundredsof acres of good land from Government or a Rajah and at once begin to make two rupees from its produce where the native only makes one. But it is all theory, It pre-supposes that everything runs smoothly, that labor is cheerful and abundant, one's agricultural neighbours willing to open their arms to the stranger, the murrain a myth, and the seasons to be depended upon. We are reminded, by works of that kind, of those admirable prospectuses, the triumphs of the Promoter's Art, in which it is clearly shown that if so many tons of some metal or other are only raised from the mine, the profits to the shareholders will be just seventy-three per cent., but the raising of the metal is the one important thing that is taken for granted. If native human nature were what it was when Adam delved and Eve span, and if farming were, on the whole, as pleasant and profitable an occupation as it must have been before the ground was cursed and man ordained to till it in the sweat of his brow, the we should have a high opinion of speculative agriculture in this country, but, as it is, we can only recommend our Eurasian friends to have nothing to say to it whatever.—*Madras Times.*

TOO MANY IRONS IN THE FIRE.

THE mail which arrived from England yesterday, brought out the prospectus of the Bombay Agricultural and Manufacturing Company. The proposed capital is £250,000. This is a considerable sum, but the public just now take more kindly to companies with large, than to those with comparatively small capitals. A curious feature of this "Bombay" Company is that no Bombay man is on the direction. The Board consists of Alderman Hadley, of London; Mr. G. Clerihew of Mauritius; Mr Frost, of London; Mr. Lewinger, of London; Mr. Maccall, late of Shanghai; Mr. Pemberton of London; and Mr. Walker, of Oldham. Of these seven gentlemen, Mr. Alberman Hadley, the Chairman, is also Chairman of the Standard Bank of London, and Mr. Pemberton is a Director of that Bank. It might be worth while knowing whether the Bank has any immediate interest in the new Company. The Directors have "power to add" to their number, but at peresent they have not induced any Bombay man to join them. If Bombay were a mere village with no trade worth naming, and if she had never been the training school in commerce of some men who are now among the most enterprising merchants of the city of London, the establishment of a Bombay Agricultural and Manufacturing Company without the material and moral support of some good Bombay names, might pass unobserved; but as now constituted, the Board has no special claim on the confidence of people in India. Yet the programme is an ambitious one, and a vast amount of local experience will be needed to carry it through. The Company propose to buy an estate of 7,000 acres in the Kunnah Valley, eighteen miles from Challisgaum, on the Great Indian Peninsula Railway, and 2/3 miles from the city of Bombay. Beyond the fact that the estate "consists of about 7,000 acres of excellent land intersected by two rivers, affording facilities for irrigation," little is said about it. The vendor is the promoter of the Company. He has "fixed the price to be paid, and undertakes to pay all the preliminary expenses attending the establishment of the Company up to date of allotment, receiving from the Company a Commission equal to 1½ per cent. on the amount of the capital subscribed." Moreover he "has covenanted" to "pay the shareholders' interest quartely at the rate of 6 per cent. per annum on the amount paid on their shares for one year from the date of allotment thus giving time for the erection and completion of the dam and the cotton mill." The Directors claim to have acquired on "very favourable terms" the sole right and licence to use and sell the Automatic Jacquard Circular and Straight Bar Knitting Looms throughout the Presidency of Bombay except Scinde. For the vendor agrees to sell the estate, together with the right to use the said looms for £92,000, of which he wishes to take half in cash and the remainder in shares. The Directors propose to direct "special attention to the production of superior cotton, and the selection of seed for distribution among the growers." They intend to build, fit, and set to work a mill for £40,000, or 40s. per spindle, and to turn out 7, 8½, and 9lbs. shirtings. They contemplate cultivating about 1,500 acres with Liberian coffee, and they calculate upon getting 5,000 cwt of coffee from the 400 trees that they will plant per acre. They mention that "tobacco of very superior quality, which flourishes on the estate under native culture can be grown at a large profit." Oilseeds, too, are extensively grown, and the Directors have determined "to erect oil-crushing machinery on the most modern principles, and, besides pressing linseed, castorseed, rapeseed, ground-nut, gingelly, moringa, rape, mustard, and sunflower, to extract the oil from the cottonseeds resulting from the cotton mill. There is an enormous demand by the railways and the numerous mills of Bombay for lubricating oils. The tea and coffee plantations take all the cake, not exported, for manure at very remunerative prices." But this is not all for "wheat, maize, rice, millet, and other cereals thrive well on the estate, and can be extensively cultivated as "the estate being intersected by two rivers has especial ad vanta ges in this respect." Then "dams built across the rivers will not only irrigate the property largely increasing its value, but will also yield a considerable revenue by sales of surplus water to the owners of neighbouring estates and farms. During the rains the waters of these rivers are charged with a rich alluvial deposit, forming an invaluable fertilizer. The Cauvery Irrigation Works, after writing off 4½ per cent. for working expenses and interest on capital, yield an excess revenue of over 81 per cent per annum. They then give a list of seven Agricultural (chiefly Australasian) Land Companies that are realizing large profits, but they of course say nothing about the kindered undertakings that have been less successful every way. They wish to be more than a mere agricultural company, for they will not only grow, but they will also spin, and weave their own cotton, they will cultivate coffee, tobacco, and cereals, they will go largely into the oil-seed crushing business, and they will sell water. And these many and diverse branches of business each of which needs special training and experience, are to be directed from London by gentlemen, none of whom may have been in India. Seven thousand acres form a large estate in the "tight little island" of England, Wales, and Scotland, but it is a small affair in the Empire of India. If gold had been discovered, and the estate had been proved to be intersected not by two rivers, but by two reefs of very promising quartz, then it might be worth a Company's while to give £92,000 for it. But the estate is innocent of reefs, and its capabilities in other directions are conjectural. Altogether, the scheme looks too vast and vague, and if the vendor of the estate gets the hard cash that he has asked for it, he should deem himself an uncommonly lucky fellow.—*Madras Mail.*

THE LAND QUESTION IN THE DECCAN.

MR. WILLIAM WEDDDRBURN, of the Bombay Civil Service discusses the important question in an able and thoughtful article contributed to the June number of the London *Statesman*. He begins by pointing out that in solving the Agrarian Problem in the Deccan, there are three chief interests to be considered—the cultivator, the money-lender, and the State; and he rightly says that no settlement can be regarded as satisfactory unless it recognises and satisfies the just claims of all three. As things now stand, each of these interests in the Deccan is in distress and demand relief. Mr. Hope's Agriculturists' Relief Act has not solved the question as we have over and over again shewn in these columns, for the simple reason that the measure does not go to the root of the evil. The Act is nothing better than a paliative, and it does not recognize the real position of the Deccan ryot. It sanctions the confiscation of the property of the money-lender, without whom the cultivator cannot even live. The supporters of Mr. Hope's Act feel a secret satisfaction in seeing the village sowcar ruined as they look upon him as a veritable Shylock. But these men shut their eyes to the hard and incontestible fact that the money-lender is an inevitability. Sir John Strachey in the debate on the Deccan Agriculturists' Relief Bill observed:—"It would be a great misfortune and mistake to suppose that Government approved the idea of a crusade against the money-lenders. Money-lenders are obviously as necessary to the Indian Agriculturist as the seed which he sows, or as the rain which falls from heaven to water his fields. Agriculture without them would probably be impossible." Yet Mr. Hope's Act practically sanctioned a crusade agains the money-lenders. Mr. Wedderburn thus describes the miserable position of the village sowcar "At present his condition is a very deplorable one for when debtors are ruined, creditors must suffer, and during these recent

famine years his hard-earned savings have gone out in advances which will never be recovered. It must also be borne in mind that the small village money-lender has seldom capital of his own, he trades on capital borrowed from the big sowcars who have their banking firms in the large towns. He is now in a miserable position, the law giving him no protection against the latter, while it has created great difficulties in his way when he tries to recover his dues from the ryot. It thus happens that for the last two years [that is to say since the passing of Mr. Hope's Agriculturists' Relief Bill into law] Marwari money-lenders have been the principal inmates of our civil gaols." This state of affairs cannot be regarded as a satisfactory settlement of the Agrarian problem in the Deccan when it is borne in mind that the ryot cannot cultivate his lands without the money-lenders' help. On the other hand the ryot finds it difficult to meet the Government demand, and the holdings of many cultivators have been sold up for arrears of land revenue. Some remedy for this condition of things must be devised, and the question is what measures of administrative reform should be adopted?

This important question Mr. William Wedderburn seeks to answer in the article under notice. He goes to the very root of the matter when he says that the revenue system must be materially modified to suit the peculiar circumstances of the Deccan districts. This has been our opinion from the very beginning. Mr. Hope himself admits that "to our revenue system must in candour be ascribed some share in the indebtedness of the ryot," Sir Robert Egerton in the debate on Mr. Hope's Bill boldly said, "Too little attention had been paid to this cause which must, in a great degree have contributed to, if it did not entirely originate the difficulties of the Deccan ryot." Sir Roberts's views did not as might be expected find favour with the "Executive Legislature." Mr. Wedderburn states that when he first came to India twenty years ago, he was a great admirer of the Bombay Revenue system, and his opinion was strengthened by his being stationed in the Southern Mahratta country where a rich black soil and a sturdy class of yeoman proprietors supplied conditions very favourable to the success of the scheme. But when he saw the working of the system in Sind, he was convinced that it was not adapted to the circumstances of all parts of the presidency. Mr. Wedderburn continues. Again an unvarying cash assessment on each plot of ground is an arrangement unsuited to the conditions of the Indus Valley. The river is constantly changing its course, so that though in one year the alluvial mud may produce a crop of grain that would do credit to the Nile, the same tract may the next year and for all time to come be nothing but a sandy waste. Similar anomalies affecting both the value and the tenures of the land developed themselves when the system was applied to the forest gardens of Kanara and the reclaimed land on the stony ridges of Ratnagiri. A powerful centralised department is intolerant of local peculiarities, and the Survey Rules rigid and unyielding have proved a very bed of Procrustes on which with many groanings, the zemindar of Sind, the mulgar of Kanara, and the Khot of Ratnagiri have been stretched, each in his turn. It is this same vice of rigidity, this refusal to recognise local peculiarites which has marred the success of the system in dealing with the Deccan ryot. The special and unfortunate characteristic of the Deccan districts is the extreme uncertainty of any harvest. It has been stated on authority that the cultivator "hardly gets a full crop once in three years, for the land is mostly unirrigated, and the rainfall very precarious; while to secure a harvest the rain must not only be sufficient in quantity, but must fall at the right intervals, and be distributed in a particular way say, a minimum of one inch during each fortnight of the rainy season. In these unfavorable circumstances the ryot who has no accumulated capital, is unable to stand alone. Living from hand to mouth he cannot, without the help of the money-lender tide over the constantly recurring years of famine and scarcity. The land can be kept under cultivation only by the combined action of the ryot and the sowcar, a partnership between labour and capital. The cardinal error of the Survey as regards the Deccan districts is that it refuses to recognise these facts. It refuses to see the ryot as he really is. It places upon him the responsibility of punctual cash payments, a liability which he is quite unable to meet, while it refuses to the sowcar his just position in the rural economy, and forces him against his wish into an attitude of hostility. It is easy to trace the error from the very commencement. In the yearly survey reports we find sketched out a pleasing picture of rural prosperity. Government, the universal landlord content with a trifling quit rent securing to the ryot all the benefit of his improvement and enterprise. But in this Arcadian vision no place was assigned to the capitalist. From this paradise the sowcar was to be excluded and thrust into the background and regarded as the wily tempter seeking to betray innocence to its ruin. Such being the sentiment, it is easy to understand the indignation which was felt when, in the course of years the real state of the case forced itself on attention. The ryot was found too feeble to grasp the advantages offered to him, and the sowcar an unbidden guest alone seemed to profit by the bounty of Government." Hence the crusade against the money-lenders. The conclusion which Mr. Wedderburn draws from a careful study of the operations of the Bombay Revenue survey, is that in the case of the Deccan districts it has erred in two ways: (1) the cultivator has been burdened with a rigid liability of punctual cash payments, while (2), the money-lender has been ignored and allowed to drift into a false position. In this view every intelligent and unprejudiced person who has carefully studied the subject will concur. To remedy the evil arising from the rigidity of the revenue demand, Mr. Wedderburn recommends a cautious return to the old system of collection of the Government demand in kind. He says "I propose to offer to the ryot a *a permanent settlement in kind*—say one-sixteenth (one anna in the rupee) of the gross produce. But to encourage him to convert his dry land into wet, I would fix for each field a quit-rent in kind, say three-sixteenths of an average dry crop, which he might at any time elect to pay instead of the share of the actual gross produce. An arrangement of this kind will suit all classes. The ignorant and apathetic man would hand over his one anna share of the ordinary dry crop of bajri or jowari at harvest time, and would not be driven to the sowcar for cash to pay the assessment; while the enterprising man would dig a well, and elect to pay the quit-rent as soon as he found that the increased value of his sugar-cane or other garden crop made that alternative profitable to him." Under Mr. Wedderburn's scheme the Government share of the produce would be collected through zemindars or farmers of the land revenue such as existed under native rule. The zemindars would realise the share of the produce due to the State from the villages handed over to their charge, and pay a lump sum into the Government treasury.

This is Mr. Wedderburn's scheme for a Permanent Settlement for the Deccan. We have all along held that the inexorable tax-gatherer who makes no allowance for the variations of the seasons, and exacts his pound of flesh without caring whether the fields have yielded anything or nothing is the veritable Shylock, and not the money-lender, but for whose aid the land could not be cultivated at all. While strongly supporting Mr. Wedderburn's recommendation to adopt "the assessment of the land revenue to the variations of the seasons, we regret we cannot approve of his proposal to collect the Government demand in kind, and to entrust its collection to a class of middlemen to be created for the purpose. The suggestion that Government should take a fixed portion of the gross produce of the land, looks quite exceptionable on paper. But in judging as the merits of any scheme, we should not merely look at its theoretic excellence. Experience has amply shewn that the practical working of the system of collecting the assessment of this kind inflicts no end of hardship and oppression on the cultivators.

The collection of the assessment in kind affords opportunities of extortion of which it is difficult to form an adequate conception. If the system of administration could be made perfect, we would strongly support Mr. Wedderburn's proposal to collect the Government demand in kind. But the fulfilment of the condition we have laid down is impossible in a country like India, where the people are utterly powerless to protect themselves against persons dressed in brief authority. Mr. Wedderburn tells us that opportunities for oppression would not exist under the system proposed by him "as the demand from the ryot would be strictly limited and defined while the zemindar would exercise no official functions, though he could under the Regulation obtain aid from the revenue authorities in realising his just dues." Now who is to determine the outturn of the standing crop? This work would we think devolve upon the zemindars or farmers of the land revenue; and here immense opportunities for oppression and extortion would exist. Again under Mr. Wedderburn's scheme it would be necessary to arm the zemindars with power to recover their dues by a summary process. If such a power is given, it is sure to be abused. *A permanent settlement in kind is no permanent settlement at all.* The benefits of such a permanent settlement as Bengal enjoys should be extended to the Deccan, otherwise the introduction of a class of middlemen would be a curse instead of a blessing. The most important thing is to adapt the assessment of the land revenue to the variations of the season. If this were done, the ryots would not object to pay the Government demand in coin. Indeed he would we believe strongly oppose the proposal to revert to the old Maharatta practice of collecting the assessment in kind. The people would appreciate the moderation of the Government demand if it should be adapted to the variations of the season. We quite agree with Mr. Wedderburn that before any new system could be brought into working order in the Deccan, the ryot's existing debts should be settled. He must be made a freeman before he could make a fresh start in life with any hope of success.—*Hindoo Patriot.*

THE PLANTING INDUSTRY OF CEYLON.

AN inquiry into the causes that have produced the present depression in the coffee enterprise in Ceylon, would not be of much value, if it omitted to take account of leaf-disease. At the same time there is room for difference of opinion as to the degree in which the blight has contributed to the downward tendency. Leaf-disease, we may be quite sure, is charged with much that should with more justice be attributed to bad management. There cannot, however, be a doubt that, had this pest not made its appearance, fewer estates would have fallen into liquidation. The disease first showed itself in 1869 in Madulsima, in the extreme eastern division of the coffee districts. Next year it had spread to the western or Kandy side, but did not become very general till the following year. It is worthy of remark as bearing upon the connexion between short crops and leaf-disease, that 1870 was the year in which there was the largest export of plantation coffee and the greatest average outturn per acre; the export being nearly 960,000 cwts, and the average per acre 5·50 cwts. Owing to the larger area brought under cultivation, the export in several succeeding years, to wit, in 1874, 1875, 1876, 1877, was above 9 ,000

cwts., but the average per acre has never again reached 5 cwts, which in four years it has fallen below three. During the seven years previous to 1870, the outturn ranged from 4·10 cwts. per acre, in 1864, to 5·22 in 1869. These figures point to the injurious effect of leaf-disease on productiveness, a conclusion which will appear all the more certain when it is remembered that this diminution in outturn since the appearance of leaf-disease has taken place in spite of liberal manuring and a higher style of cultivation than was carried on previously. The planter has therefore good reason to conclude that his diminished returns are to a considerable extent due to the ravages of disease. Meanwhile, as Dr. Thwaites, late of the Botanical Gardens, Peradeniya, says in his report for 1874, it seems to be conclusively established "that judicious cultivation enables the coffee tree to produce a succession of profitable crops, notwithstanding it may suffer from periodical attacks of leaf-disease." This is well exemplified by the obvious fact that no where has the disease committed such havoc as in native plantations, where cultivation is almost entirely neglected. Previously to 1870 planters were divided into two opposite camps—the party that advocated manuring, and the party that opposed it. How long it might have been in the then state of things before a satisfactory solution should have been arrived at, it is not easy to say. The inroads of leaf-disease have led to the matter being speedily and practically settled in favour of high cultivation.

The effects of short crops and low prices might have been mitigated had planters been less exclusively dependent on the one product coffee. Having their eggs all in one basket, a mishap to it could not fail to be followed by serious consequences. Coffee must for many years to come prove the staple product, but had they been as fully alive ten years ago as they are now to the importance of cultivating other products, their losses on coffee would have been more than made up. But here again they had to pass through the school of adversity before they could be taught the potential wealth of resources that surrounded them. First to be mentioned among these new products, though not the most important, is Liberian coffee, which grows at elevations unsuitable to the Arabian species. At the end of 1877, there were, according to Ferguson's *Handbook* (from which the following figures are mainly derived), about 500 acres planted with Liberian coffee. There seems to be some difficulty in determining the area under cultivation at the end of 1880, the estimates varying from 4,000 acres to 7,000 or even 10,000 acres. Though not enjoying complete immunity from the attacks of leaf-disease, the growth and productiveness of the trees have not, so far, been affected by it. It remains to be seen whether this coffee will command a ready sale in the home market. London dealers are said not to appreciate it very highly, but it has been favourably received in America.

The cultivation of tea, though still in its infancy, is likely to become one of the most important industries in the island. Begun about the year 1867, at which time about 10 acres were planted, it made small progress till 1875 when the acreage was estimated at 1,080. Since then the increase has been more rapid, the area under tea at the close of last year being estimated at close upon 9,300 acres. As is the case with Liberian coffee, the increase of tea cultivation does not imply a reduction of the area under coffee, the soil and climate best suited for the one being more or less unsuited for the other. The rapid rise of this industry is seen from the exports for the past five years, as given in the Customs accounts :—

Year	lbs.	Value. Rs.
1876	757	1,907
1877	2,105	3,457
1878	19,607½	20,990
1879	95,969	85,229
1880	189,752	——

This does not represent the whole annual outturn, there being a large local consumption. The crop for the current season is estimated at about 500,000 lbs. The Ceylon planters are sanguine that they will be able to produce a finer tea than that of Northern India, and at a cheaper rate. In support of the latter consideration they adduce their superiority in the matter of cheap transport and labour, as well as in being nearer the commercial centre. As to quality, they appeal to their long list of awards at the Melbourne Exhibition, and to the comparative results of the analyses of Ceylon and Indian teas made by the Victorian Government analyst. Indian tea-planters need not grudge their southern brethren this consolation, considering the cold reception accorded to Ceylon teas in Mincing-lane. The colonists are more indignant than discouraged at their failure to conciliate the vested interests of the London brokers, upon whom they are at present inclined to turn their backs altogether, looking to Australia as the market for their teas.

A still younger industry than tea is cacoa, which gives promise of being a valuable addition to the vegetable products of Ceylon. Demanding a lower elevation and more sunshine, it can be grown in situations where the Arabian coffee cannot. It is grown successfully in districts as widely apart as the Central Province, Galle on the South-West, and Trincomalie on the North-East; a fact which indicates the suitability of Ceylon for the plant. On many estates where climate and soil are suitable, cacoas are planted between the rows of coffee trees. This makes it difficult to judge precisely what progress has been made in extending their cultivation. At the end of 1877 only 500 acres were planted. At the end of last year this had increased to about 5,400 acres. Little has yet been exported, the demand for seed having nearly exhausted the indigenous supply. Ten cwts. were exported in 1878, 42 in 1879, and 191 in 1880. In the matter of spices, with which Bishop Heber's hymn has associated the name of Ceylon in the minds of the Sunday school-going youth at home, the island scarcely keeps up its reputation. It is estimated that about 30,000 acres are cultivated with cinnamon, but the area is hardly at all extending. It shows the fluctuations that occur within a short period in certain articles of produce, that though there are at the present moment prosperous coffee planters in the island who made their first step on the road to fortune through remunerative investments in cinnamon, its cultivation does not at present yield a profit sufficient to attract capital. Cardamoms have of late been profitably cultivated, but the area covered by them is not great, though increasing. In 1877 there were less than 200 acres: at the end of last year there were over 1,000 acres.

But of all the newer products now being cultivated in Ceylon, it is to cinchona that the planter most looks for the re-adjustment of the financial equilibrium so grievously disturbed of late years. It is hardly possible to obtain anything like accurate information as to the extent of this cultivation. There are considerable patches in different parts of the country devoted to cinchona alone; but almost all estates, especially the older ones, have trees planted along road-sides or in the midst of the coffee. In some instances, cinchonas are planted only in places where the coffee trees have died out but in other estates, almost the whole acreage has been planted with them in regular rows between the lines of coffee. Some of the species are grown at lower elevations than have usually been considered suitable. Thus they are said to grow in the Yatiyantota district on the western slope, at 500 feet; and at Kalutura, about 30 miles south of Colombo, nearly at the sea level. The number of cinchona plants growing in Ceylon at the beginning of this year is estimated in Ferguson's *Handbook* at from 50,000,000 to 100,000,000. *C. succuirubra* is the most numerous, being reckoned at more than one-half. The remainder consists of *C. officinalis*, and *C. calisaya*, with such varieties as *C. ledgeriana* and *C. pubescens*. Of course, the majority of these are very young, say, not more than three years of age, the cultivation not having increased at a very rapid rate till about 1 77, when the depression in coffee forced planters to look about them for something to take its place. It will consequently take some five or six years before there will be any marked increase in the export of bark. By that time a serious fall in price may happen; and in any case, it can hardly be expected that prices will continue to maintain their present level after Ceylon, in common with other parts of the world, has begun to pour a largely increased supply into the home markets. But the Ceylon planters do not despair of a profit on the cultivation even, should prices fall to one-half or one-fourth of their present rates. The following is the official Custom's returns of the export of the cinchona bark for the past eleven years :—

			Value Rs.
1869	...	28 oz. ...	50
1871	...	80 packages ...	818
1872	...	11,547 lbs. & 694 pkgs.	61,102
1873	...	44,836 ,, ...	32,667
1874	...	40,854 ,, ...	25,277
1875	...	19,152 ,, ...	17,963
1876	...	14,932 ,, & 1 pkg. ...	14,720
1877	...	72,127 ,, & 1 ,, ...	88,783
1878	...	186,797 ,, ...	1,71,292
1879	...	507,368 ,, ...	5,19,986
1880	...	1,161,989 ,, (say) ..	12,00,000

It is not expected that the rate of progress indicated by the figures of the past two years, will be kept up during the next three or four years there being reason to suspect that the hard time recently experienced led many planters to cut or bark their trees prematurely.—*Madras Mail.*

AN AGRICULTURIST'S TOUR IN BELLARY.

THE Government have published a valuable report by Mr. C. Benson, late Acting Superintendent of Government Farms, on tour that he made on the Bellary district last autumn. He says :—"The tour was a short one, but afforded me an opportunity of extending my experience of South Indian farming to a set of conditions of which I had previously but little knowledge. This is, however only the third district in the presidency which I have as yet been allowed to visit, although I have been in the service of Government for nearly seven years. My first opportunity of personally gaining an insight into native farming was, not afforded me until I had been nearly five years in India, and thus my knowledge of the country was until recently very small. This tour is further only the fourth that any officer of the department has up to the present time been allowed to make in the plains and yet blame is often cast on them for not appreciating the good points of native farming, although their opportunities of becoming acquainted with these points have been few. Hearing and reading chiefly of the defects of the native system; and working out the conclusion to which official statistics point agriculturally my opinion of South Indian husbandry was not a flattering one, as I showed in a paper I laid before the Famine Commission. Further experience does not lead me to modify in any important particulars m previously expressed opinions, although I can now better appreciate the difficulties with which the ryot has to contend, and also the good point of

his practices as far as I have become acquainted with them. With e very extension of my experience, the conviction also grows upon me of the great difficulties of bringing home to the ryot information regarding the manner in which his practices can and should be altered. The two most important points on which reform is urgently required—the use of a better plough and the manufacture and use of manure,—are of such a nature as to render demonstration of the necessity for change of the greatest difficulty. Everything, as far as I can see, points to the advisability of energetic action on the lines mentioned in my Cuddapah tour report; but even with the greatest possible effort progress can only be slow. Unless Government are prepared to act energetically, and on a far reaching system in the matter, the hope of doing any good to the country at large must be very small, and it is scarcely worth while to carry on our work in a 'half-hearted and experimental' manner."

The Board of Revenue observe that "Mr. Benson's tour was confined to the month of August, when crops were on the ground, and it is therefore difficult to understand how he arrived at the conclusion that the agricultural operations of the district are carried on in a 'lazy and perfunctory manner,' or on what ground he basis his assertion that the system in Bellary 'is the most inefficient cultivation he has ever come across.' Subsequently, however, when describing the mode of cultivation more particularly, he practically retracts discharge, and shows that the operations are conducted in an intelligent and skilful manner. Mr. Benson appears to be puzzled to account for cholam and korra being the staple crops, and says; 'I am unable to suggest any reason why they should so exclusively occupy this position.' The Board says that the "reason why these cereals are more largely cultivated than other grains is that, being the staple food of the people, there is a large demand for them and it pays the ryot to grow them just as in England, it pays the farmer to grow wheat and barley. In regard to deep ploughing and the alleged prejudices of the ryots against this and other approved modes of farming, it is observed by the Board that the only way to overcome prejudice is to demonstrate practically that scientific farming pays; and a few model (not experimental) farms conducted on commercial principles established in the midst of the ryots' holdings would produce a greater effect than a long series of lectures at the School of Agriculture. The Board consider that this practical test is what must be insisted upon as the first and most important step towards the improvement of agricultural in India." The Government say that they have perused the report with interest, and that it is a valuable contribution to the literature on the subject. They concur wit the Board in desiring that tours be undertaken as frequently as possible, and would be glad of any suggestions the Board may offer to that end.—*Madras Mail.*

SINGULAR EXPERIMENTS WITH SHEEP.

THE *Times'* Paris correspondent writing on Thursday says:—An invitation having been sent to me, I went to-day to Pouilly-le-Fort to see some very important experiments on the farm of M. Rossignol, a veterinary surgeon. Pouilly-le-Fort, which is a few miles from Melun, in the Department of Seine-et-Marne, is a large farm reached by one of the splendid roads, lined with limes and acacias, which intersect that flourishing department. Just now a harvest is expected there which is called "electoral," the peasants often being influenced in their votes by a good or bad harvest, voting, according as it turns out, for or against the Government. M. Pasteur, one of the scientific glories of France, made to-day experiments in connection with his latest researches on that malady dreaded by agriculturists, called "charbon," a sickness which rages more especially among sheep, the mortality of which produced by it is estimated in France at several million francs a year. Without entering into the details of M. Pasteur's theory, I must give a few wods of explanation, in order that the bearing of to-day's results may be understood. According to M. Pasteur's theory, then, this malady is communicated to animals, and more especially sheep, by infected grass. The grass, however, is only infected where animals that have died of the disease have been buried. In these spots worms, after having fed on the diseased carcases, rise through the pores and fissures of the soil to the surface, collect round the roots of plants, are swallowed by the animals, and thus communicate to them the deadly virus. M. Pasteur has collected these worms. He separated the virus they contain, subjected it to chemical action, and gave it a graduated virulence extending from the most harmless to the virulent state. He then set up the theory that by inoculating the virus at different progressive degrees, he might eventually inoculate the severest virus without the animals suffering any effect from it; in other words, that by inoculation the animals might be protected from "charbon." These theories, conceived in the laboratory, discussed before the Academy of Medicine, and being warmly combated, required to be tested by practical experiments, and the Agricultural Society of Melun requested M. Pasteur to make them in the Department of Seine-et-Marne. On the 5th of May M. Rossignol's farm and 60 sheep were placed at M. Pasteur's disposal. Ten of these sheep were left untouched in order that they might later on serve for comparison. Of the remaining 50, 25 were marked with a hole in their ears, and were inoculated, the first time on the 5th of May, and the second on the 17th. On the 31st of May none of the inoculated sheep had lost fat, or gaiety, or appetite. On the 31st of May the 50 sheep were taken without distinction and inoculated with the strongest virus. M. Pasteur predicted that to-day the 25 sheep not inoculated would be dead, and that the inoculated animals would show no symptoms of sickness. To-day, at half-past one, a number of spectators, among whom were M. de la Rochette, President of the Agricultural Society of Melun; M. Patinot, Prefect of the Department; M. Tisserand, Director of Agricultural Matters at the Ministry of Agriculture and Commerce; and several cavalry officers and veterinary surgeons came together to witness the results. Things turned out as M. Pasteur had foretold. At two o'clock twenty-three of the sheep which had not been inoculated were dead. At three o'clock died the 24th, and the 25th an hour later. The twenty-five inoculated animals were sound, and frolicked and gave signs of perfect health. Only one of the twenty-five inoculated animals was yesterday feverish, and the fever disappeared to-day. It was caused by the animal having designedly been inoculated with too strong a dose of the virus. At three it had gone, and the sheep was eating again. The twenty-five carcasses have been buried in a fixed spot, and on the infected grass which will grow over it, experiments are to be made with the inoculated and non-inoculated sheep. But the result is already certain, and the agricultural public now knew that an infallible preventative exists against the disease in question. This preventative is neither costly nor difficult, for a single man can inoculate 1,000 sheep in a day.—*Times*, 3rd June 1881.

THE PAPER MANUFACTURING INDUSTRY.

IT is stated by one of our contemporaries that the Government have suggested to the Madras Railway Company the desirability of charging special rates to merchants transmitting fibre for the manufacture of paper, so that facilities may be afforded for the growth of an industry that ought to receive every encouragement. The object with this order has been issued is a commendable one and may have the effect of encouraging the manufacture of paper. But the question is whether in the manufacture of paper in the mofussil or in the outskirts of the presidency town, the manufacturers use fibres, or whether they utilise waste paper and rags which have for years been the chief materials used in this country for making paper. There are two or three small factories, beyond the municipal limits, where paper of inferior quality used in making boards is manufactured. The quantity turned out is not very large, but is sufficient to meet the demands of the local trade. Paper know as country cartridge is also made and used in many of the public offices and private establishments for wrapping purposes, and at one time the masters of the petty pial schools in the town were pretty large consumers of country paper since they insisted on their pupils having "copy books" made of it. This was when the system of writing on cadjan was getting into disuse. But now that paper of English manufacture is so largely available and at such cheap rates, it can hardly be expected that the manufacturers of country paper will be induced to take a greater interest than they now do in an industry that, though it has a bright future before it, cannot be expected to make head way unless some enterprising European capitalists, with the necessary appliances, enter heart and soul into an undertaking that might prove remunerative.

About two years ago, the Government of India called upon the local Government to ascertain if paper was made from aloe fibre in the districts, and at what cost. The collectors of some of the southern districts were asked to supply the necessary information as it was known that aloes were largely available in parts of South Arcot, Tanjore, and Madura. It was ascertained from the tahsildars that the system adopted by the manufacturers was such that each quire of paper cost between Rs. 1-8 and Rs. 2, and that unless a very large quantity is made up, the cost could not be very much less. If a quire of country paper is to cost as much as a ream of paper imported from France, it is not likely to be in demand, and it will never pay the manufacturer. Some time ago a European gentleman, Mr. Routledge, applied to the Government for information on the growth of certain descriptions of fibres which he said could be largely utilised in the making of paper, but whether that gentleman is likely to push his investigations further, or whether he has abandoned all intention of starting a paper mill in India, we are not in a position to state. That a well-managed paper mill in Southern India will obtain large support from the Government and private persons there can be no doubt. In Calcutta the Bally Paper Mills Company is a very successful undertaking, and the orders sent to the mills, we believe, are as much as can be supplied. The demand for paper in Bengal and the North-West Provinces is sufficient to keep the mills going, so that the company is unable to supply small orders sent from Southern India. A short time ago an attempt was made to establish a paper mill at Allahabad under the joint stock system. An influential Board of Directors was constituted to work the company which looked forward to substantial support in the north-west. The Bengal papers have not recently afforded information in connection with the enterprise, but if it has been started, it must be doing business by stealth, and will perhaps some day find it remunerative. A few months ago we recorded the fact that a paper mill was started by some of the Maharajahs in Central India. We believe Maharajah Scindiah has set up a paper mill, and like Maharajah Holkar who had started cotton mills and finds them paying schemes, hopes to make a good thing of it. In Southern India sufficient capital has lately been forthcoming to start gold mining, beer-brewing, stable-keeping, and other companies. These will, it is hoped, flourish and give their shareholders handsome returns. But we think that a paper mill, if set up and properly worked in a part of the presidency best adapted for it, will turn out a successful venture, and its projectors may take full advantage of the concession which the Government has decided that the Railway Company should afford in the conveyance of fibres for the manufacture of paper.—*Madras Standard.*

THE CULTIVATION OF LAND IN KAZEROON (WESTERN PERSIA).

ALL land in Kazeroon is private property. If the cultivation be undertaken by the landowner himself, he has to provide seed for an acre of one *gao* of cultivation (the *gao* representing the extent cultivable with one ox), *viz.*, 1,000 lbs. of wheat and 1,000 lbs. barley, and pay about 14 krans (the kran being equal to 11*d.*) for the labour of ploughing and sowing. He pays in kind 11 per cent. of the yield of his harvest to Government, and 20 per cent. to the reapers, who have to undertake all the duties appertaining to the collection of the harvest and the carriage into the stores of the landlord. The landowner also pays 2 to 4 per cent. for threshing or treading the corn. Other than a landowner undertaking a cultivation has to pay to the land-owner 9 per cent. in kind from the outturn of his harvest as rent for one *gao* of land, and 14 per cent. to the Government as tax; his other expenses are the same as those incurred by a landowner. Consul-General Ross states that the agriculturist of Kazeroon are of two classes, *viz.*, the "ryot-i-padishah" and the non-ryot, the former being always looked down upon by all classes, and subjected by Government to more oppression than the others. The ryot cultivator thus not only pays more taxes to Government, but has to pay his taxes in cash instead of in kind, and at 30 per cent. above market value. He is also obliged to give a certain quantity of straw to Government officials whenever required. A ryot, when a landowner, and cultivating his own grounds, has to pay 15½ per cent. on his harvest in cash, and at the above enhanced valuation. A poor ryot pays about 60 krans annually in cash to Government; and there is another class of ryots who are obliged to buy at 30 per cent. above market value, a certain portion of the produce received by Government as taxes. A wealthy ryot is entirely at the mercy of the authorities, a sum of about 1,000 krans being annually levied from him. The value of one *gao* of land is from 100 to 600 krans, according to the locality. To commence cultivation an outlay of about 15 tomains (the tomain being equivalent to 9*s.* 3*d.*) is necessary, and is distributed as follows:—One ox, 50 krans; seed, 60 krans; labour, about 14 krans; straw and cotton seeds, 16 krans; and sundries, 10 krans. It is also necessary for a ryot when undertaking four or more *gao* of cultivation, to maintain at least one donkey. The quantity of grain required for cultivating one *gao* of ground is about 2,000 lbs. In the case of "saifee" or summer cultivation, no distinction is made by Government between a ryot and a non-ryot; "saifee" sowings are always undertaken by proprietors of water and agriculturists conjointly, the proprietor providing the water and ground, and the agriculturist finding the seed, labour, implements, &c. Should the water owner, however, not be at landowner as well, any other landowner would be but too glad to permit his lands to be used for "saifee" cultivation gratis, inasmuch as the soil becomes enriched by manuring, which the "saifee" cultivation necessitates. The time taken for "saifee" sowing is about seven months, the following being cultivated—tobacco, water melon, marsh melon, vegetables, cotton, sesame seeds, lentils, rice, gram, &c. A tax of 20 per cent. *ad valorem*, on the outturn, is levied by Government, three-fifths of which is payable by the proprietor of the water, and two-fifths by the cultivator, and the balance is equally divided between the propritor and the cultivator. Rice and grain, however, form an exception, and are cultivated under the following conditions:—The agriculturist recoups himself for the quantity of seed supplied by him after harvest. He then has equal shares with the water owner, who alone pays Government taxes as follows:—If a ryot, he pays three-fifths of his share to Government; if a non-ryot, he pays only half, the agriculturist paying no tax on his share. In all cases it is thoroughly understood that the Government share of the produce is to be carried to Government store at the cultivator's expense. The approximate value of the produce on the spot is for wheat from 40 to 60 cents. per maund (the maund being equivalent to 30 lbs. avoirdupois); barley, from 25 to 30; gram, from 50 to 80; sesame, from 70 to 100; maithee, from 15 to 20; dhall, from 15 to 20; cotton, from 2½ to 3 krans; and rice, from 50 to 80 cents. The annual expenses of a ryot cultivator in Kazeroon, with a wife and two children, are 10 tomains per annum. The yield of wheat and barley is from ten fold to twelve fold in a good year, and three fold to four fold in a bad one; rice in a bad year, yields twenty fold, and in a very good year, sixty fold; cotton five fold in a bad year, and ten fold in a good year. Irrigation is generally conducted by means of kanats, and the water in all cases is allowed free passage across grounds, even though not belonging to the proprietor of the kanat; should the proprietor of a kanat not wish to undertake any "saifee" cultivation, he could still be made liable by Government to such taxes as may be due by the cultivator; no taxes whatever are levied on gardens in Kazeroon. In the cultivation of the poppy, which is largely grown, the proprietor provides the land seed, and the expenses of sowing the cultivation is then made over to the ryot, who undertakes all the labour necessary for the tending of the crop till the season of cultivation, when the proprietor pays for the labour of incision, about one kran per man per day, the outturn is then equally divided between the landowner and the ryots. The cultivation of opium is also untaxed. A good deal of water is wasted in Persia owing to the long distances it has very often to travel before reaching a land eligible for its security against raids, &c., and to damages constantly sustained by watercourses, which, owing to the social conditions of the country, it is very often beyond the reach of the ryot to travel out of the jurisdiction of his village to repair. There are also large tracts of fertile land which remain waste owing to their proximity to the main roads, as no village having cultivators on such spots can possibly prosper or enjoy the least immunity from the exacting demands of Government officials, and the thefts and robberies committed by the "Illiyat" tribes on their passage along the country thoroughfares.

AMERICAN CULTIVATION OF JUTE.

ATTENTION is being directed in America to the advantages of cultivating jute instead of importing it from India, whence 32,471 tons was taken to the United States in the year ending June 30th, 1880, the value being above five million dollars. The demand is, of course, not so much for paper manufacture as for textile fabrics and cordage. The South requires eighty million pounds of butts for bagging to cover her five million bales of cotton, as much more to sack her cotton seed, cake, meal, rice, and grain, while the great West and North, and California will probably require two hundred million pounds of the fibre for sacking grain and vegetables.

The *Paper World*, our contemporary published in Holyoke, says that California has been raising enough jute for several years, to furnish bagging for her other crops, and Louisiana and many other Southern States contain lands which are unquestionably admirably adapted for jute growing. In Louisiana the crop is considered a sure one, and can be raised as easily as corn. The yield of jute is estimated at from 2,000 to 4,000 pounds of fibre per acre, and the price of jute butts is from three to six cents. The plants are not molested by insects and worms, and, indeed, are said to be less subject to disaster and bad weather than any other crop raised in the South.

Professor Waterhouse, of Washington University, St. Louis, says:—"All that is now necessary to the certain success of the undertaking is the invention of a cheap and rapid means of disintegrating the fibre. In the preparation of the fibre, nothing but chemical or mechinal agencies can successfully compete with the cheap manual labor of India; and convert the culture of jute in the United States into a great and prosperous industry."

Our contemporary tells us that "the few jute factories which have been established in the United States are doing a profitable business. They import the raw material from India. The import duties on jute and its manufacture are as follows:—Jute tow \$20·00 per ton; gunny cloth 3 cents. per lb.; bags, composed wholly or in part of jute, 30 per cent. *ad valorem*; bagging, valued at 7 cents. or less per yard, 1½ cent. per lb.—over 7 cents. per yard, 2½ cents. per lb.; jute yarns 20 per cent. *ad valorem*; butts \$6 per ton. On all other manufactures, in whole or in part of jute, 30 per cent. *ad valorem*. With such a premium on the domestic culture, of jute and with the certainty that it will yet be in enormous demand, there can be little doubt that American ingenuity will devise some process which will effect the cheap and rapid disintegration of the fibre mentioned by Professor Waterhouse.

ARTESIAN WELLS IN AUSTRALIA.

LATE correspondence in *The Australasian* on the subject of artesian wells shows how strong is the interest felt by all classes in this branch of water-supply. It is an interest that is increasing as time goes onwards, and it is natural that it should be so, for the future prosperity of Australia depends much upon the success which may attend attempts to improve by artificial means the water-supply, more especially in the less favoured districts. The occupation, for instance, of the Murray Valley, of the wide plains of Riverina, by settlers and farmers has brought our population face to face with this question. It may be said with some truth that even so early in our history it has been forced upon us by pressure of population, and, as this pressure increases, so will increase also the importance to be attached to the question of water-supply itself. Why the subjects of conservation of water, of artesian wells, of irrigation, should have lain so long dormant in a country where their successful development would evidently prove so highly beneficial is, perhaps, due to the fact that our population is mainly derived from stocks inhabiting countries where there is, indeed, perhaps too much water rather than too little. It may be said that we have to unlearn our instincts, and to acquire new ones. We have to acquire painfully and by degrees, through hard necessity the required experience and knowledge to enable us to make the most of our somewhat limited rainfall. We may learn much from the practice of other people, but we must ourselves study the conditions under which it will be necessary for us to apply that borrowed knowledge. If the agricultural and pastoral resources of the southern half of the Australian continent are to be fully utilised, and if our wide territories are to be made to support our growing population, it must be by fully utilising every drop of water that can be caught and saved of the somewhat scanty rainfall that comes to the share of this land. I propose now to discuss the question of water-supply only so far as it relates to artesian wells. In order to have something like a safe foundation to start from, it will be

necessary to clear the ground by inquiring what are the principles upon which the action of an artesian well depends. These principles seem to be very generally misunderstood, and it is essential to a proper understanding of the subject that they should be stated.

The action of an artesian well depends upon hydrostatic principle of a simple nature. Water is a body whose molecules are displaced by the slightest force. Acting under the influence of terrestrial gravitation, it has a tendency to find its level, that is to proceed from any given level to a lower level. Thus it not only flows from higher to lower positions along channels, water-courses, and rivers; but also through porous rock beds which crop out at the surface and extend to great depths into the earth's crust. These porous rock-beds may be imagined as an infinity of minute parallel tubes. The principle which has especial relation to artesian wells is that of the equilibrium of the same liquid in communicating vessels. Take, for instance, the case of a tube of the form of the letter U. If water is poured into one arm, it will rise in the other until its height is the same in each, or until it flows over the orifices. If now we were to insert a third tube between the two arms, the water would rise in it and sink in the other two until equilibrium was restored, and if this tube were shorter than the height at which the water stood in the other two, there would be an outflow from it, either continuously, if the supply were maintained, or until the equilibrium were restored.

We have here a statement of the laws on which the action of an artesian well depends. The strata penetrated by a artesian bore must, therefore, fulfil the following conditions:—(1). The water bearing stratum must crop out at the surface at a higher elevation than the orifice of the bore; (2), it must be contained between two impervious strata; (3) the strata must be either curved so as to form a basin, or the outflow must be so far impeded as to keep the water at an elevation higher than the orifice of the bore.

These are the simple principles upon which the action of artesian wells depend. Before speaking of those existing or possible in this country, it is further necessary to see broadly, but with some mental clearness, the physical features of the Australian continent, both superficial and subterraneous, as well of the past as of the present. The Australia which we see to-day is the result of unceasing operations of natural agents, carried on during the vast ages which lie behind the present. In inquiring how these operations have been carried out, it is necessary to commence with that which is, and to endeavour therefrom to reconstruct ideally that which was.

The Australian continent may be described as a great basin, having an opening southwards. The rim of the basin is indicated by the encircling coast range, which commences, say, in the western part of this colony, extends through New South Wales, Queensland, Northern and Western Australia, and terminates somewhere near the western end of the great Australian Bight. As compared with the area of the continent, this coast range is close to the margin. Between the points of commencement and ending there is no coast range, but merely isolated elevations of the older formations standing above the general surface. The most noteworthy feature is that this coast range represents the margin of an enormous basin of Palæozoic and Mesozoic rocks. The interior of this basin is so far filled in by Kainozoic and later formations, that it is only the higher inequalities of the older formations that now appear as isolated ranges, or even mere peaks, protruding through them.

That which has been called by Professor Dana the continental structure is well marked in Australia; that is, the higher coast range faces the larger ocean, and the lower coast range the lesser ocean. We can see this on the east and west coasts. Between the eastern and western coast ranges extends a wide and comparatively level expanse, which is but little raised above the level of the sea. The folded and compressed Palæozoic rocks of the eastern coast ranges, and the denuded granitic areas of Western Australia, which are now the surface, not only suggest enormous denudation, but also the "crumpling up" of the borders of a rigid continent between two sinking areas of the earth's crust. The folding of the lower Palæozoic rocks has been at right angles to the forces at work, and the folding being nearly meridional, those forces have acted from the area of the Pacific on the one hand, and the area of the Indian Ocean on the other. The "sketching out" of the Australian continent took place mainly during the Palæozoic ages. Immeasurably later, and probably towards the close of the Kainozoic time, when the Australian continent, as we now see it, began to come into existence, there were wide corrugations of the crust of the earth nearly at right angles to the earlier ones. These had the effect of tilting up the whole southern part of the continent on an east and west axis, of depressing the northern half, and they tended to, if not caused, the separation of New Guinea to the north, and Tasmania to the south.

In order to bring out prominently the features to which I desire to draw attention, as bearing upon the subject of artesian waters, I must refers to the geological evidence.

This evidence will be drawn partly from observations as to the present condition of Australia in its physical geography and geology, and partly from those records which have been placed upon the pages of the great stone book of Nature. The pages of this record are the strata of the earth's crust. The whole record itself may be likened to a history in three volumes, the Palæozoic, the Mesozoic, and the Kainozoic ages of geologic time. This record is very imperfect. Long chapters are lost, or only remain to us in fragments. The language in which it is written becomes more ancient and difficult to interpret as we search backward in the earlier records. The signs in which the language it written are only decipherable by the trained eye of the geologist; but the narrative, so far as it has been expounded, is on the whole, clear and consistent. I shall quote from the pages of this record, and I shall commence to do so at that part which may be likened to the middle chapter of the third volume, the Miocene period of Kainozoic time.

At the present time we observe that mountainous masses or ridges, or mere peaks, protrude through the Kainozoic, and more recent formations that level off the great extent enclosed by the circling coast range. It is certain that these elevated tracts of the older formations have not been ever wholly submerged since the Mesozoic age, and it is highly probable that the land surface has, indeed, been continuous—that is, it has existed as dry land—during part of that time itself. Without going so far back, it is sufficient to point out that the water-shed of the Murray basin has existed as land during the Kainozoic age, and I propose to take as my illustration the general course of geological events since the Miocene period.

At this time the land in the southern half of Australia stood much lower—was, in fact, depressed several hundred feet in reference to the sea level—than it now is. The line along which the sea beat round the then land is at the present time far—several hundred feet; in fact—above the present coast-line. A somewhat coarse limestone, filled with remains of a marine fauna, indicating a warmer climate than that we now have, gives us the approximate limits of land and sea then. It skirts the feet of the Gipps Land mountains; it appears at Mordialloc, Corio Bay, and Hamilton; and it fills in the lower part of the Murray Valley. Australia was, probably, at that time a continental island, but of slightly less extent to the south than now. The mountainous regions of the south-east were higher. A vast table-land extended round from Victoria to to the eastward, at an elevation of, perhaps, 2,000ft. to 3 000ft. above the sea level, dominated by still higher chains of mountains. At that far distant time not only was the temperature of the sea warmer than it now is along our southern coasts, but the climate of the land was warmer. The remains of the marine creatures tell us this as to the sea and the remains of plants which are preserved in the Miocene deposit tell us this of the land. If we desire to picture to ourselves the physical aspect of Australia in its southern portion—we must, in imagination restore back to the high grounds, to the hills and mountains, all the materials which now fill in the central basin and which overlie the beds of Miocene age, not only of the central basin, but also on the coast side of the Dividing Range. We may do this as regards the Riverina basin, taking it as an example. Riverina, taking that term in its widest sense, is that tract from which the drainage falls towards the Murray River, or which would do so were all the streams permanent. Its boundaries to, the westward must be taken as being the Palæozoic hill-country commencing at Cape Jervis and extending to the Barrier Ranges, west of the Darling River. Further to the northward, or rather to the north-east the Palæozoic formations do not, so far as I am aware, appear as surface rocks, the water-shed being of later Mesozoic or even Kainozoic age. To the east and south the rim of the basin is formed almost wholly of the older Palæozoic rocks.

The mental picture I arrive at of the Riverina basin in the Miocene age, is that of a more or less hilly country, draining through its valleys to the southward by a great river. The sea at that time extended far within the Murray Valley. How far is not at present determinable, but sufficient is known to indicate that it may have been as far as about a line drawn from Mount Arapiles towards and beyond Wentworth. Into this sea the then representative of the present Murray would discharge its waters. Where were the sources of this river is uncertain, perhaps within the tropics.

To the south were islands, of which the Grampian Mountains were certainly one. To the south-east and east, as I have said, there was a mountainous tract, having a central plateau, with still higher chains of mountains. Numerous volcanoes poured out sheets of basaltic lava, and levelled off its upland valleys. The remains of the table land still exist in the high plains of Wonnangatta, Omeo, Maneroo, and probably New England. To the westward was also a hilly and, perhaps, insular country, now represented by the mountains of South Australia.

Following the depression of the continent, during which the Miocene beds were formed, there appears to have been a re-elevation of the land of wide extent. It spread out most probably to Tasmania, to New Guinea, and its eastern limits may have been marked by the Great Barrier Reef. Thence onwards until now there is evidence of continual oscillations of the land, but the maximum depression or re-elevations probably never much exceeded 1,000ft. above or below the present levels.

During the enormously long ages which have elapsed since that Miocene land existed, the streams flowing from the Coast Range and from the secondary ranges of the Australian interior have been unceasingly removing the denuded surface, excavating valleys, and transporting the resulting materials to lower levels. Thus they have greatly filled in the central basin—that is, filled in the sea bottom during periods of depression. During periods of re-elevation, materials were spread over the low-lying [illegible] whilst elsewhere channels were cut back into older deposit

Evidence of this may be seen everywhere in the Australian interior, in the mud plains, in the tortuous river channels, and in the isolated remains, of that widespread formation known to geo'ogists as the desert sandstone.

The results of these processes are that large tracts of still older formations have been denuded—in fact, planted off—down to the great granite masses that everywhere form, in fact, the foundation of the Australian continent. The surrounding water-sheds have been lowered and the central basin so far filled in, that wherever the streams can flow at all, they do so at a fall that can scarcely be more than, if even as much as, one foot to the mile.

My illustration is the Riverina basin, but my remarks will apply equally, with but slight local modifications, to the whole of the still greater basin of which it forms a part.—*Australasian.*

ARTESIAN WELLS.

It has come to be recognised on all sides that all that is necessary to render valuable a large part of Australia is a plentiful supply of water. And when the question is raised of the best method of supplying this all proposals come under one of two heads, the surface conservation of the rainfall, and artesian wells. The first of these methods is that which has hitherto chiefly been relied upon, but of late there has been a tendency to look more for the necessary supplies to the boring of artesian wells. The wells have this advantage over the dams, that they are less expensive to construct and cost nothing to keep in repair, while if the water rises to the surface, an abundant and permanent supply is secured independently of all conditions of rain or drought. It would have cost the town of Sale a very great outlay to obtain, and a continuous outlay to maintain, by means of a reservoir and pipes, a supply equal to that which it is now in possession of by merely sinking a well to a depth of 282ft.

When the question of sinking artesian wells is practically raised, the dependent question comes—in what positions can such wells be sunk with a reasonable prospect of obtaining water? A competent scientific authority has in two recent issues of *The Australasian* treated this question in an interesting and instructive paper. The question, fortunately, is one to the solution of which geological science can contribute important assistance. The conditions requisite for an artesian well in which a permanent supply of water will rise to the surface are uniform, and are easily stated. They are—first, an underlying impervious stratum in something like a basin-shapped depression, next a porous, absorbing stratum, charged with water taken in at the outcrop of the stratum at such an elevation as to be higher than the surface of the ground at the proposed well, and finally an impervious stratum superincumbent upon this, preventing the water from rising to the surface. Where such conditions exist, all that is necessary is to sink a bore through the upper impervious stratum so as to tap the saturated layer beneath and the imprisoned water, hitherto locked up under strong hydrostatic pressure, rushes freely to the surface. These are the general conditions; but to the special question whether they exist in any particular place it is often the case that geological science can only give an indefinite and uncertain answer. It can only do this because the whole of the conditions can hardly be perfectly known. All that science can generally affirm is that the known facts are favourable or unfavourable to the expectation of finding water, and that this or that place is presumably better situated than that other for a successful issue to an experiment.

In the meantime we have some general facts that are on the side of encouragement. It is now demonstrated that enormous quantities of the rain-waters of Australia are absorbed in the soil, and never find their way visibly to the sea. As the sea must, nevertheless, be their ultimate destination, we can only suppose that they are making their way by incessant subterranean filtration to our coast lines. There must be an immense number of points at which a deep bore would tap an overcharged stratum, from which the compressed water would read rise vertically to the surface rather than force its way against the resistance it has to encounter on its course to the sea. Every such a point represents a potential artesian well. For the discovery of those points we must look in a great measure to actual experiment. As we have said, our expectations that science can indicate these with accuracy are very limited. We must remember that science is seldom in possession of the required data for such an inference. Every bore that is put down for the purpose of discovering water is more than an individual experiment. It is also a source of valuable knowledge with regard to the geological formation of the country that may be useful for future guidance over large areas.

In some parts of Australia are to be found surface indications that give rise to a high degree of probability that deep springs might be found by boring, that would force the water to the surface. Take for instance, the remarkable mud springs on the Warrego and Paroo rivers, which evidently come from vast depths, quite uninfluenced by season changes, or fluctuations of rainfall, and which are also equally evidently forced up by great subterranean pressure. We can hardly avoid the belief that these prove the existence at a great depth of a stratum charged with water under great hydrostatic pressure, water which succeeds in making its way up to the surface through a few weak points in the overlying strata. What is wanted is an extensive testing of the country under proper scientific guidance. Many shafts will be sunk with no result, save the enlargement of our knowledge of the geological formation, which may be useful in other attempts. But some may be expected to pierce the enormous stores of water which the deep-lying soil of Australia must contain, slowly filtering to the sea. When these inexhaustible sources of supply have been largely tapped, the provision of Nature by which so vast a proportion of our rainfall is absorbed by the soil will be seen to be conducive to human convenience and utility instead of being as it has hitherto appeared, a cause of enormous and irremediable waste.—*Australasian.*

OPIUM CULTIVATION IN PERSIA.

OPIUM of the new crop is already coming into the market, and the yield, it is generally believed, will exceed by twenty-five per cent that of the largest known before. This increase is attributable to two causes, *viz.*, the healthy growth of the plant, and the greater extent of its cultivation. Some, however, firmly believe that the increase may be safely taken at 25 per cent. over that I have stated above. From the steadiness with which the production of Persian opium has increased during recent years, it would be no easy matter to mark the utmost limit of this dangerous rivalry with India, as the capabilities of Persia to grow the drug are unbounded; under existing conditions she may eventually increase her production to about twenty thousand chests. But this is not all. Above Ispahan there are hundreds of thousands of acres of land lying waste for want of water, and which is separated from the river Aboo-Koran by a range of hills, of which the base at some points is only about four miles across. The scheme being found feasible Mohtamed-i-Dowleh, the Armenian, during his Governorship of Ispahan, about forty years ago, undertook to cut a passage for the waters of the river, when required to flow in the direction of the waste lands alluded to. The work was pushed on to some distance—I believe about three-quarters of a mile in the slow rise of the hill—after which a tunnel was to have been made, but the Mohtamed-i-Dowleh died, and operations came to a stop. Now, if this project be revived and carried through, it would certainly strengthen Persia by at least an additional fifteen thousand chests of opium, which would interfere most prejudicially with the opium revenues of India. To remedy this prospective evil, the British Government ought to forego its theory of free trade with regard to Hong-Kong by levying a heavy duty on opium, the import of other than Indian. If they did this, the price of Persian opium would decline in proportion to the amount of duty leviable in Hong-Kong, and would have the effect of damping the energies of the growers. They would also be driven to devote their labours more to the cultivation of food grain, which is year by year being more and more neglected, with the dire effect of adding to the ever-increasing distress of the general population. The increasing exclusion of grain cultivation has caused much anxiety to the Persian Government, which at one time threatened to destroy the poppy of any of the ryots that had exceeded the prescribed limit. But it has never been strong enough to carry its threats into execution. Until about fifteen years ago the local produce of grain in Yezd was sufficient for its consumption for seven months in the year, where as now, in consequence of the supersession of the poppy, the local supply only lasts about four months, and for the rest of the year Yezd is dependent on Fars, Kurman, Kashan, and Soltoonabad in Koordistan, for its staple food, in former years supplied by Fars alone. The levy of a heavy duty on Persian opium in Hong-Kong will not only maintain the opium revenues of India, but will also save Persia from self-inflicted famines. Properly speaking, Indian opium goes to Hong-Kong sad dled with a heavy duty already levied in India though by a different mode of collection. Hence it cannot be said that Hong-Kong is a free port to the Indian opium. Where, then, is the justice of allowing Persian opium, only slightly weighted by comparatively paltry charges, to compete with the Indian in the China market? Having written so far, I am reliably informed that in the midst of the gathering operation, the poppy has, in most parts of Fars and in some of those of Ispahan, been damaged by a specie of insects called "Ro" in these parts, which either feed on the leaves of the plant or eat their way through the head. Owing to this the greater part of advances made to growers for delivery of the drug this season will necessarily be deferred to the next.

The weather here just now is pretty warm, and a good deal of fever and diarrhœa prevail in consequence of the people in general indulging in sour fruit and sleeping in the open air. When they get ill, they ignore the sources of their malady and explain "What would become of us if our dietary precautions were neglected?" I am sure with such a good climate, aided by proper food and proper medical treatment in sickness, the percentage of mortality might be minimized to almost *nil*. Dr. Odling, attached to the Telegraph station here, does a great deal of good to those who go to him for advice. What a blessing it would be to Shiraz if there were a dozen Dr. Odlings.—*Times of India.*

THE SUGAR INDUSTRY IN MANILA.

OVER the signature of VERITAS, a correspondent of the *Diario de Manila* writes, under date of 1st May, as follows, regarding the local sugar industry in the Philippines:—

The Luzon Sugar Refinery is working under a privilege obtained by its proprietors for cleansing and refining sugar, and it has resulted in a good

business for its owners; but another object has been attained, which is not to be overlooked, owing to its transcendency and is as follows:—Since its foundation the most earnest endeavour has been made to convince the planters of the sugar-cane, that it would cost them the same for producing a very bad article, and of little acceptance as to produce a sound one, which would be in constant demand that the system of mixing honey with the sugar of the new crop is in every way ruinous; first and chiefly, because it gives a name well deserved to the Philippine sugar which is qualified as adulterated in the worst manner, and because the honey placed in contact with sugar of recent manufacture has the property of diminishing ten times its volume, crystalized as it might otherwise be with great facility.

The planters succeed in augmenting its volume, but at the same time incur the risk of prejudicing the quality, and it has been most evidently shown that while nobody buys the mixed goods, the pure sugar is always saleable. The *farderos* are those who up to the present have been the principal buyers of the goods which are sold as sugar, paying to the planters a price less remunerative; and they in their turn, by means of manipulation, in which by adulteration all sorts of malpractices are carried on, which are only known by them, have given as a result an article sent to the markets for consumption which occupies nearly the last place amongst raw sugars; while the fact is that the Philippine sugar is beyond dispute the best without exception in the world. This is not only a saying proved by competent judges, both by analysation and other means; it is accepted, beyond all discussion that the juice extracted from the sugar-cane of these islands has for richness no rival.

It is more to be wondered at when it became known that the cultivation of these soils is of the most primitive style; what would it be if they were better cared for?

Recent circumstances have been the cause of certain determinations taken by merchants, which induced the belief that the exporters (*farderos*) cannot continue their abuses as hitherto; on the contrary, they have either to behave in good faith or close their factories altogether, and thus put an end to a trade which has resulted in nothing but discredit to one of our principal sources of wealth.

The refinery which we have allude to above has contributed much towards placing our sugar in the place where it should be; the country may be congratulated upon possessing the element which has given such a satisfactory result.

NOTES ON GUMS, RESINS, AND WAXES.

BY C. G. WARNFORD LOCK.

THE following economic notes, from the journals of recent travellers seem worthy of reproduction in a collective form:—

SENEGAL GUM.—The product of acacias which grow in the neighbourhood of the Sahara. During the harmattan winds, the gum exudes from the bark of the trees in tears, and solidifies in the open air, the amount of exudation depending upon the force and duration of the wind. The production in 1871, was 3,161,906 kilo. (of 2·2lb.)

MPAFU.—A large tree yielding a sweet-scented gum-resin, much valued by the natives on the Victoria Nyanza.

Gum Arabic is produced by *Acacia gummifera* (*Mimosa gummifera*, *Acacia coronillæfolia*, *Mimosa coronillæfolia Sassi gummifera*), a scarcely known plant of Morocco, occuring abundantly as a thorny bush in the lower region of south and west Morocco, according to the testimony of the natives who call the plant *alk tlah*. The gum does not seem to be collected in the western portion of its range in South Morocco, but in Demnet, whence it is carried to Mogador. Possibly it is only in the hotter and drier regions of the interior that the gum is produced in quantities to be worth gathering. At any rate, its gum is yielded only during the hot, parching months of July and August, and increases according to the hotness of the weather, and the sickly appearance of the tree being least after a wet winter and a mild summer.

Some accounts suppose the Moroccan Gum Arabic to be derived from *Acacia arabica*, which is found in Senegal, but all the inquiries made by Consul R. Drummond Hay, for Hooker and Ball, agree that this plant, the *alk awarwhal* of the Arabs, is not found in Sus, no such tree existing either north or south of the Atlas Mountains, its gum being brought from Soudan, and of inferior quality to that of *A. gummifera*. It is further stated that this latter species grows chiefly in the provinces of Blad Hamar, Rahamma, and Sus.

ELEMI.—This used to be brought in large cakes to Bembe (West Africa), and is said to be very abundant at not many days' journey.

JUTAHY-SECA.—A resin or gum which exudes from the bark of the jutahy tree of Brazil (*Hymenæa mirabilis*); universally employed for varnishing native pottery.

COPAL.—Red gum copal is almost entirely the product of the Mossulo country (Angola), though it exists farther north, as at Mangue Grande. Until 1858, it was a principal export from Ambriz to America, but the war stopped it. According to native accounts, it is found below the surface of a highly ferruginous hard clay, at a depth of a few inches to two feet. It probably extends much deeper, but the natives are too lazy to look for it. It occurs in irregular flat masses up to several lbs. The natives only dig for it during and after the last and heaviest rains in March—May, and restrict the export to maintain the price. No trees and but little grass grows over the spots. The tree is said to be abundant in the woods adjoining the inner side of the wilderness in Usambara (East Africa), but does not extend farther inland.

A great staple of the district traversed by the newly-made road from Dar-es-Salaam, through the Wasamaro country, is gum copal, which is found in many parts. This fossil resin seems to exist, even in the richest diggings, only in patches, as though it were produced by isolated trees. The natives appear to work the country nowhere systematically; they sink test-holes, and, on finding traces of the resin, work that part thoroughly. In many places, test-holes have been made and the place abandoned as useless, although not far off a patch has been well worked. The fossil resin, now found underground usually in red sandy soil, is undoubtedly the produce of the same species of tree as still exists in these jungles, and which now yields an inferior sort of resin. The difference between the two products seems to arise from chemical or molecular change effected by time. The copal tree grows throughout the Uzamaro country, and is by no means confined to the sea coast, but is even more abundant inland beyond the first coast ridge. It is not seen, however, where the old limestone formation of the interior makes its appearance.

CHIAN MASTIC.—The mastic country of Chois is usually flat and stony, with little hills intervening, and with rare streams. Rain is destructive of the harvest; frost is rare, but much to be feared. The resin is a product of *Pistachia lentiscus*. The principal villages engaged in the industry are Calimassia, Saint Georges (south of Anabato), Nenita, Mesta, and Kalamoti, besides which there are about a dozen of minor importance. The mastic occurs in white grains, varying in size from a pin's head to a pea. The shrubs yielding it are about the height of a man. It occurs also in Africa and Arabia, but always of inferior quality, though no satisfactory reason has yet been adduced for the fact. In July—August, a great number of incisions are made in the stems of the shrubs, and renewed three or four times. Repeated visits are then made to collect the resin which exudes. A shower of rain during this period produces disastrous results, by washing away the resin. There are four qualities of mastic:—(1.) Cake mastic is composed of large pieces, and is considered the best by connoisseurs; it is sold chiefly for use in the seraglios, all Turkish women chewing mastic; its price is 120 to 180 piastres, and even more, per oke of 1,300 grm. (2.) Mastic in large tears is worth 90 to 100 piastres ordinarily. (3.) Mastic in small tears or pearl is worth 70 to 85 piasters and is used industrially. (4.) Mastic mixed with fragments of leaves and sand is used to make so-called "mastic brandy," the well-known Turkish liqueur, called *raki*. It is made by digesting mastic in the brandy obtained from dry grapes re-distilling the product, and flavouring with aniseed and sugar. The best qualities of mastic are used in the Levant; Europe imports the inferior grades for making varnish.

CHIAN TURPENTINE.—Afforded by *Pistachia terebinthus*. That which exudes from the shrub is very white and aromatic, but the quantity is very limited.

INDIA-RUBBER (from *Ficus elastica*).—The collection of the rubber in Assam is conducted under rigid restrictions in the case of all trees growing; in the timber reserves, but cannot be enforced on scattered trees. The Chardwar rubber plantation has an area of 80 square miles. The exports from Lakhimpur in 1871 were 260 2/3 tons, value £8,310. Immense forests of these trees existed on both banks of the Subansiri river, and on other streams, but the reckless treat ment they received from native lessees of the forests caused their ruin. In 1870, the leasing of these forests ceased, but there is now little or no rubber left in the plains of the Lakimpur district. The trees grows to heights of 15 to 85 feet, and its girth, when fit to be tapped, is 18 inches to 6 feet. A high yield for the first tapping of a tree is 35 to 40 lbs. of rubber. It is then allowed to remain untouched for three or four years, when another collection is made, but the yield is then much less. It is estimated that the forests of Cachar could yield upwards of 2,000 cwt of rubber annually. It is stated that the trees yield most during the rains.

Of the India-rubber, 20,000,000 lbs. are annually exported from Para (Brazil), chiefly derived from *Siphonia elastica*, but a few other species are admitted. The utmost yield from each tree is one gill. In the wet season, from February to July, the gum is weak and the tapping is stopped. The trees will grow on the *terra firma* when planted, but their seeds naturally lodge in lowland swamps. Trees properly planted and cared-for yield well in fifteen years. Brazil is being gradually cleared of its rubber, gatherers now go to the Tocantins, Madeira, Purus, and Rio Negro, and will soon clear there also. Strauss's method of preparing rubber, instead of smoking, is to drop the milk into alum solution; it is stated to be superior, but is not adopted.

India-rubber plants grow on the slopes of the Cameroons mountains (West Africa), but the people do not yet know their value. India-rubber trees abound on the River Djour, in the province of Bahr-el-Ghazal. The natives of the Marutse-Mabunda empire, on the Upper Zambesi, trade in India-rubber with the tribes to the west.

The *Landolphia* vine is known from Pangani inland all the way to Handei (in Usambara, East Africa), and at Magila the rubber is made into balls for export.

The giant creeper, *Landolphia*, grows chiefly on trees near rivers and streams in Angola, and the Congo. Every part exudes a milky juice when cut or wounded, but this will not run into a vessel placed to catch it, as it dries so quickly as to form a ridge on the wound which stops its further flow. The blacks collect it by making long cuts in the bark with a knife, and as the milky juice gushes out, it is wipped off continually with the fingers, and smeared on their arms, shoulders, and breast, till a thick covering

is formed. This is peeled off their bodies and cut into small squares which are then said to be boiled in water. From Ambriz the trade in this rubber quickly spread south to the River Quanza, where considerable quantities are exported.

Within 20 miles of the coast from Liawa and the Lindi estuary (Masasi Rovuma, East Africa) the forest becomes almost entirely formed of India-rubber vines, affording an abundant supply of fine India-rubber, at present gathered only in a very desultory manner by the natives, who gash the plants, and collect the rubber as it issues in a liquid form, and dries hard after short exposure to the air. Rolled into orange-like balls, it is taken to Lindi, where what is worth 7 to 8 dols. fetches 2 dols. The width of the belt is 15 to 20 miles. On the Victoria Lake (Central Africa) are one or two kinds of trees which produce caoutchouc of good quality.

Dr. Kirk has just determined, with accuracy, the plant which yields the best East African India-rubber, and has obtained seeds of the species for introduction into India. It occurs in great abundance along the newly-made road from Dar-es-Salaam, in a west-south-westerly direction, for about 100 miles towards the interior of East Africa, through the Wazamaro country; it is apparently but little affected, except in the immediate neighbourhood of the villages, by the reckless mode of tapping employed. In many parts, a native can still collect 8lbs. of rubber daily. There are five species, but only one is considered worth tapping.

Rubbers and Guttas of Borneo and Sulu.—The Kadyans and their Murut neighbours collect a quantity of gutta-percha and India-rubber in the surrounding forests. The gums are afterwards manufactured into lumps or balls, and conveyed to Labuan for sale. The gutta is obtained from four or five species of the genus *Isonandra*, all large forest trees. The trees are felled and their bark is girdled or ringed at intervals of two feet, the milky juice or sap being caught in vessels formed of leaves or cocoanut shells. The crude juice is hardened into slabs or bricks by boiling, and is generally adulterated with 20 per cent. of scraped bark. Indeed, it is said that the Chinese traders, who buy up the gutta from the gatherers, would refuse the pure article in preference for that containing bark, to which the red colour is mainly due.

India-rubber in the north-west districts of Borneo is the produce of three species of climbers, known to the natives as *manoongan*, *manoongan putih*, and *manoongan manga*. Their stems have a length of from 52 to 100 feet, and a diameter rarely exceeding 6 in.; the bark is corrugated, and coloured grey or reddish-brown. The leaves are oblong, geen, and glossy; the flowers are borne in axillary clusters, and are succeeded by yellow fruits, of the size of oranges, and containing seeds as large as beans, each enclosed in a section of apricot-coloured fruit. These fruits have a delicious flavour, and are much prized by the natives. The stems of the India-rubber creepers are also cut down to facilitate the collection of the creamy sap, which is afterwards coagulated into rough balls by the addition of nipa salt.

The fallen gutta trees lie about in all directions in the forest, and the rubber-yielding *Wilughbeias* are also gradually, but none the less surely, being exterminated by the collectors in Borneo, as throughout the other islands, and on the Peninsula, where they likewise abound.*

It was formerly thought that gutta-percha was the produce of only one species of (*Isonandra gutta*), but that obtained from the Lawas district is formed of the mingled saps of at least five species, the juices of a *Ficus*, and of one or two species of *Artocarpeæ*, being not unfrequently added as adulterants. The Bornean *gutta soosoo*, or India-rubber, again, is the mixed saps of three species of *Willughbeia*, with the milks of two or three other plants surreptitously introduced to increase the quantity.

The gutta trees are slow to attain maturity, and are difficult to propagate, except from seed. The *Wilughbeias*, on the other hand, grow rapidly and readily lend themselves to both vegetative and seminal methods of propagation; hence these are epecially deserving of the attention of the Government of India, where they may reasonably be expected to thrive.

There are, doubtless, yet many thousand tons of rubber and gutta in the Bornean woods, but as the trees are killed by the collectors without any thought of replacing them, the source of supply must recede constantly farther from the markets, and prices will rise in consequence. The demand for India-rubber from Borneo is of quite recent growth, yet in many districts the supply is already practically exhausted.

In Assam, Java, and Australia, rubber is afforded by *Ficus elastica*, which is cultivated for the purpose. There are many milk-yielding species of *Ficus* in the Bornean forests which, with careful experiment, may possibly be made to contribute remunerative quantities. The Malayan representatives of the bred-fruit family also deserve examination, as an excellent India-rubber is derived from *Castilloa elastica*, a South American plant of this order.

LAC.—Secreted by an insect (*Coccus lacca*), on the branches and twigs of certain jungle trees, principally *Khusum* (*Schleichera trijuga*), *plas* (*Butea frondosa*), and *bier* (*Zizyphus jujuba*). The lac from the first is more esteemed than that from the others. To some extent, the lac is found occurring, so to speak, spontaneously, and is collected by forest tribes, and brought by them to the fairs and bazaars for sale. Where, however, there is a regular trade in stick-lac, propagation of the insect is steadily carried on by those who wish for a certain and abundant crop. This propagation is effected by trying small twigs, on which are crowded the eggs or larvæ of the insect, to the branches of the above-named species of trees. These larvæ are technically called seed. The larvæ, shortly after sowing, spread themselves over the branches, and, taking up position, secrete around themselves a hard crust of lac, which gradually spreads till it nearly completes the circle round the twig. At the proper season, the twigs are broken off, and on arrival at the factory, are passed between rollers, which admit of any degree of approximation. The lac is thus crushed off, and is separated from the woody portion by screening. It is next placed in large tubs, half full of water, and is washed by coolies, who, standing in the tubs, and holding on to a bar above by their hands, stamp and pivot about on the heels and toes, until, after a succession of changes, the resulting liquor comes off clear. The lac having been dried, is placed in long cylindrical bags of cotton cloth of medium texture, and about 10ft. long and 2 in. in diameter. These bags when filled, are taken to an apratment where there are a number of open charcoal furnaces. An operator grasps one end of the bag in his left hand, and slowly revolves it in front of the fire; at the same time, an assistant, seated at the other end of the bag, twists it in the opposite direction. The roasting soon melts the lac in the bag, and the twisting causes it to exude, and drop into troughs placed below which are often only the leaves of *Agave americana*. When a sufficient quantity in a molten condition is ready in the trough, the operator takes it up in a wooden spoon, and places it on a wooden cylinder, some 8 to 10 inches in diameter, the upper-half of which is covered with brass—in some places the freshly-cut, smooth, cylindrical stem of the plantain is used for this purpose. The stand which supports the cylinder, gives it a sloping direction away from the operator. Another assistant generally a woman, now steps forward with a strip of *Agave* in her hands, and with a rapid and dexterous draw of this, the lac is spread at once into a sheet of uniform thickness, which covers the upper portion of the cylinder. The operator now cuts off the upper edge with a pair of scissors, and the sheet is lifted up by the assistant, who waves it about for a moment or two in the air till it becomes quite crisp. It is then held up to the light, and any impurities, technically "grit," are simply punched out of the brittle sheet by the finger. The sheets are laid one upon another, and, at the end of the day, the tale is taken, and the chief operator is paid accordingly, the assistants receiving fixed wages. The sheets are placed in packing-cases and when subjected to pressure, break into numerous fragments. In the fresh state, the finest quality has a rich golden lustre.

The dark-red liquor before referred to, as resulting from the washing is strained, in order to remove all portions of woody fibre and other foreign materials. It is then passed into large vats, where it is allowed to settle; the sediment is subjected to various washings and at last allowed to settle finally, the supernatan liquor being drawn off. The sediment, when of the proper consistency, is placed in presses, from which it is taken out in the form of hard, dark-purple cakes with the manufacturer's trade-mark impressed upon them. This constitutes what is known as lac-dye. The dye which is thus separated from the lac by washing is said to be the body of the insect—not a separate secretion.

It might appear that some mechanical arrangement would be more efficacious and economical for washing and separating the lac from the eye, but human labour is so cheap, that this is not the case. The daily pay of the women is 1d. to 1½d.; of the men, 1½d. to 2d. No evil effect on the feet of the stampers is to be observed. The great and sudden oscillations of price in the London market render this trade very risky, and the aniline dyes have well-nigh rung the knell of lac-dye in European industry.

In Assam, a small quantity is produced in the district of Darrang. In some districts, the insect is artificially reared on the *jhuri* tree (*Ficus cordifolia*).

INDIAN WHITE WAX.—This is produced by the female of the *Ceroplastes ceriferus*, an insect allied to the *Pela* of the Chinese, whose product is so largely used for making candles for the Buddhist temples. The Indian insect deposits its wax in small masses upon the twig and branches of several trees, but more particularly on the *arjun* [*Terminalia Arjuna*]; it does not appear to have ever been propagated, nor has the wild product been collected in quantity. Though an article of undoubted value, it would perhaps scarcely repay expenditure of European time and capital; but the natives might surely render its cultivation a very profitable undertaking. The wax is soluble, or nearly so in boiling alcohol, also in benzine and ether, but only very slightly in turpentine and carbonic disulphide (CS_2). Its composition is $C_{r3}H_{26}O$. It is found at many widely distant points throughout Sirguja, and is abundant, and suitably situated for experimental cultivation, on the *arjun* trees growing upon the embankment of the Purulia lake.

THE GUM TRADE OF SOMALI LAND (EAST AFRICA).—The gum, or *habak* always sold in grades, bears the name of *ankobib*. On sifting, it is always found mixed with a small quantity of other sorts which make weight in the balance; these are the *habak eudde* and the *habak follala*. The incense, or *luban*; sold in grades, takes the name of *beiho*. The *saphi*, or "triage," is divided into three qualities. The 1st, *fasous*; the 2nd, *nagoua*: the 3rd, *medgigel*. The *saphi*, or "triage," is made into *doukans*, when the arrivals are not too great, by women and children, who are paid about 6d. a day.

The myrrh has but one quality, but it is necessary to be on the guard against the admixture of false myrrh, of the same colour, but

more powerful odour, which the Arabs call *addi*. It is easy to recognise this latter, which always appears oily.

The *maidi*, called in Europe *gum elemi*, is a kind of incense in large bleached tears. It presents the same grades as incense, and buyers aim especially at preserving the tears unbroken to heighten the value.

The *aleti*, or *mourcoud*, is a grey gum, with an exquisite odour recalling that of ambergris.

The *addi*, or false myrrh, whose odoriferous wool is mixed with the wood of *djirmeh*, has an odour when burnt closely resembling that of "seraglio pastilles."

The *fallah-fallah* is a resinous bark, which is burnt to give off a peculiar odour, under the name of *habat droun*.

Statistics of the annual receipts of gums and incenses at the ports of the Medjourtine coast :—

	Bohars.
Bender Ziyada	250
Bender Gasem	1,200
Abou Regabe / Bender Saad	900
Borah	300
Gandala	500
Bender Khor	1,000
Ras Orbe	250
Meraya	1,500
Guersa	200
Guesli	400
Bender Felik	700
Atlouia	1,004
Total ...	8,200

The bohar is equal to 136 kilo., or, say 8,200 bohars are about 1,200 tons; this increases to 2,000 tons in a good year.

Myrrh reaches two places only—

Bender Gasem	30 Bohars.
Borah	8 „

Haffoun, in 1877, received 25 bohars.

Magnificent incense-trees, two to three feet in diameter, are found on the lofty mountains towards the north coast of Somali Land. Mareyeh, an important village, lying over 30 miles west of Cape Gardafui, has a large export of myrrh and incense.

Obeidh, the capital of Kordofan, is the centre of a large trade in gum, which is collected in the woods by the women and children, and taken to their villages, where it is disposed of to petty itinerant traders, for ultimate dispatch to Europe.

Moroccan Gum Ammoniacum (which must not be confounded with the Persian product of *Dorema Ammoniacum*, or *ushak*), is an object of commerce with Egypt and Arabia, where it is employed, as of old, in fumigating. The plant affording it is called *fashook* in Arabic, and has been hitherto referred to *Ferula orientalis*, or *F. tingitana*; but Ball and Hooker consider it decidedly an *Elæoselinum*, probably *E. humile*. Leared was told that this plant grows at a place two days from Mogador on the Morocco road; but Hooker and Ball were assured that it is found nowhere along that route, nor nearer to it than El Araiche, a place lying north of Morocco city, which is confirmed by information gathered, by R. Drummond Hay, to the effect that it occurs near Morocco, and chiefly around Tedla.

Gum Sandarch is a product of *Callitris quadrivalvis* (*Thuja articulata Frenela Fontanesii*) a tree indigenous to the mountains of North Africa, from the Atlantic to East Algeria, its eastern limit being undetermined. The resin, once a reputed medicine is collected by the Moors, and exported from Mogador to Europe, where it is used in varnish-making.

Euphorbium gum is produced by *Euphorbia resinifera*, a tree confined to the interior of Morocco. The juice flows from incisions made with a knife, and hardens and drops off in September, the produce being abundant only once in four years. The people who collect the gum tie cloths over their mouths and nostrils, to exclude the small dusty particles, which provoke intense sneezing. The gum once had a wide medicinal use, but the trade in it is now rapidly declining, and its consumption is restricted to veterinary practice, and as an ingredient in a marine paint?

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

THE usual Monthly General Meeting was held on Thursday, the 21st July.

W. H. Cogswell, Esq., President, in the Chair.

The Proceedings of the last Monthly Meeting were read and confirmed.

The following Gentlemen were elected Members :—

Messrs. A. W. Hurle, J. E. Weingartner, C. Hudson, the District Engineer of Jessore; the Manager of the Bungtint Tea Company; Baboos Bahal Dass Holdar and Amrita Naryan Acharjea Chowdry, and Captain W. H. M. Francklyn.

The names of the following Gentlemen were submitted for Membership :—

The Rev. Albert Williams, Serampore,—proposed by the Secretary, seconded by Mr. R. Blechynden.

Edward Dellus, Esq., Calcutta,—proposed by Mr. W. H. Cogswell seconded by Mr. J. G. Meugens.

W. MacNab, Esq., Tea Planter, Hatibanda, Nowgong,—proposed by Mr. G. L. Kemp, seconded by Mr. S. H. Robinson.

Augustus Bauermeister, Esq., Merchant, Saigon *viâ* Singapore,—proposed by the Secretary, seconded by Mr. H. A. Firth.

Manager of the Meleng Tea Estate, Assam,—proposed by Mr. A. B. Inglis, seconded by Mr. D. Cruickshank.

W. D. Pratt, Esq., District Superintendent of Police, Midnapore,—proposed by Mr. H. Cornell, seconded by Mr. W. A. C. Beadon.

Baboo Ramnarain Chatterjee, Calcutta,—proposed by Baboo P. C. Mittra, seconded by Baboo P. C. Ghose.

Rejoined.—Manager, New Gola Ghaut Company, Assam.

CONTRIBUTIONS.

1. Report on the Botanical Garden of South Australia for 1880. Presented by the Director, Dr. R. Schomburgh.
2. Memoirs of the Geological Survey of India, Vol. 18, Part 1. From the Director.
3. The Indian Forester, Vol. 7, No. 1. From the Editor.
4. Proceedings of the Asiatic Society of Bengal for May 1881. From the Society.
5. A seedling of *Amherstia nobilis*. From Major R. H. Fanshawe.
6. Seeds of *Musa Ensete*. From Dr. G. Schwenfurth.
7. Four kinds of Tobacco seeds. From the Director, Department of Agriculture, N.-W. P.

GARDEN.

The Superintendent's Monthly Report was read, of which the following are extracts :—

"Propagation work both ornamental and orchard is being pushed on vigorously. I would beg to suggest that for the clearance of stock that is accumulating a General reduction of 25 per cent. in price of all classes of plants be made to Members. I feel certain that it is practicable to reduce the same 50 and in some instances 75 per cent. after the rains; but to enable the Garden to do so, I would point out to Members that their co-operation is necessary in applying for their allowance of plants promptly. Plants propagated during the rains have to be kept confined in pots to meet indents from Members who in many instances fail to send for their allowance when due. The plants thus imprisoned for a long time in pots when they should be in the earth making growth and gathering strength naturally suffer and when deferred till after the following rainy season they must suffer from rot, earth-worms and the thousand other vicissitude of plant life. The delay in claiming allowance of plants also increases the work of the garden hands when they would under the conditions suggested be engaged in other work tending to the interests of Members.

If this suggestion is acted upon, and an increase in the number of Members thereby obtained, it will be possible, I have no doubt, to make further reductions in prices, and enable the Society to import plants under special arrangements, and supplied to Members at such easy terms that will do away with any monopoly that there may be.

I have known as much as one hundred rupees paid for a plant, which, under such circumstances as the Society could arrange, should not have cost more than ten rupees at the outside.

As the specimen coffee plants in the garden are now fruiting, parties, interested in their cultivation will have an opportunity of satisfying themselves by personal observation, that the Arabian is *the* plant for Bengal. The Arabian is bending with its load of berries. The Liberian is almost bare. This latter plant may be of good foliage and that is all that can be said of it, as respects Lower Bengal."

The suggestions in the above report were favorably received by the Meeting. It was also thought desirable to notify to Members, not desirous of receiving their annual supplies of vegetable and flower seeds, that they could obtain a double share of ornamental plants in place thereof.

In reference to the above notice about Coffee from Arabian stock, the Secretary alluded to a remark in a recent issue of the *Englishman*, that the crop is said to be a fair average one in the Chittagong Hill Tracts. He further drew attention to the opinion given by a Committee of the Society, so long ago as 1843, on coffee raised in that district. An attempt was made about that time to form a Joint Stock Company for the cultivation of the plant to that locality, but it was not carried out. In respect to coffee cultivation in Ceylon, a correspondent, in a recent issue of the *Gardener's Chronicle*, adds the following remarks in an account of that island and its capabilities :—

"Of Liberian Coffee, I need say but little. It is now being largely planted in the hotter parts of the island, and is a strong and rapid grower, suffering but little from leaf-disease. It ripens its fruit at irregular seasons, and requires less care in pruning and cultivation, it does not seem to be thought much of in the London market, though in America it sells well. From what I heard I doubt its ever taking the place of ordinary coffee, which, notwithstanding all losses, is still one of the most valuable crops that can be grown."

DEVELOPMENT AND IMPROVEMENT OF THE FUTURE WOOL TRADE OF INDIA BY THE INTRODUCTION OF LONG WOOLED SHEEP FROM SOUTH AMERICA.

The following communication from Captain J. F. Pogson on the above subject was next submitted :—

The people of Beeloochistan and adjacent parts of Afghanistan, derive a very handsome and annual income from the sale of wool to British merchants resident at Kurrachee, the natural sea port of the Punjab and through it, of all Afghanistan.

The wool at present produced in the Punjab is of inferior quality, but if Rams and Ewes of superior breeds were to be introduced from a port of America, possessing a warm climate, improvement would at once take place and an opening and employment be secured for the rising generation of Europeans.

I will show presently that the Punjab is destined to be a great wool-producing country, that is if the Home authorities do not extinguish the production by placing obstructions in the way of the European proprietor or gentleman sheep farmer.

The salt range of the Punjab is remarkable for possessing a breed of wild sheep, and it follows that where the wild sheep thrives, the proper breed of domesticated sheep will do the same, and further that the cross breed between the two will produce a hardy long wooled sheep of very considerable value to the sheep farmer. In the rains the various breeds (seven in number) of sheep the produce of imported stock, would be driven up to graze in suitable part of the salt range, and I presume the localities would be selected as farm stations in the winter, or after the rains the sheep would be sent to graze in the plains where shearing operations would take place, and the pressed and packed wool be sent down the Indus and Jhelum rivers to Mooltan, whence water carriage by steamers and cargo flats to Kurrachee would be available or, if preferred, the Indus Valley Railway could be resorted to.

To carry out the project, I would suggest the formation of a Joint Stock Company with sufficient capital to import 20 rams and 100 ewes of each of the seven breeds described beneath.

The Government of India as well as that of the Punjab, would, I think, feel disposed to encourage such an undertaking, and the former might sanction grants of grasing land being allotted to the Company on the most favorable terms.

With this introduction, I beg to invite the attention of the Council of the Agricultural Society of India to the extracts which are subjoined, and have been taken from the columns of the *Delhi Gazette* of the 8th August 1879, in which part of the journal kept by Mr. Paul, Civil Engineer, employed by Bogota Government was published.

Bogota, is the capital of the United States of Colombia, South America, and the difficulties of transit alluded to having been removed since 1878, the importation of sheep could be very easily carried out by private enterprise, having the sanction and support of the Home and Indian Governments.

Extracts from Journal—

"Tuesday, April 8th, 1873.—*Javoncillo to San Vicento.*

About wool. Owing to the difficulties and expense of transport the price of wool is very high, and therefore does not figure in the list of exports; but with the opening of a line of railway bringing the coast into quicker and cheaper communication with the interior, it would become one of the chief exports of the country, and in such an event Sogamuso would become an important centre for wool.

The following are some of the principal breeds of sheep of the country, *viz.*:—

Oveja (sheep) *de chircate.* Is small, the meat is bad, wool coarse but strong, is not subject to disease. Its fecundity is great, the fibre of the wool is about thirteen inches in length. It is very hardy, thrives in poor and exposed situations. The wool is used in the manufacture of mattresses, coarse blankets, &c. The price ranges between £5 and £8 per 100lbs. without being washed. This species is used principally for its wool.

Common sheep *Oveja comun.* The ordinary Spanish species, but fed on good pastures and in a temperate climate. Is large, meat savory, wool short but very fine, it is used in the manufacture of cloths for trousers, fine blankets, baize, and woollen stuffs generally for out-door and in-door wear. Its price varies from £2-11-4 to £4 per 100lbs. This species is reared principally for its meat.

Oveja Cari-pintoda. Black or speckled-headed. Is larger, and the quality of the meat better than the previous one, but its wool is not so fine. It *is* reared in the State of Bozaka.

Oveja Merina (Merino)—Was introduced into the country in 1825. It flourishes in the States of Boyaca Candinamarsca, and at Conception in Salitander. Though the original stock has been so mixed with other kinds of sheep still the fineness of the wool has not degenerated but nearly retains its original characteristics.

Oveja Dishley. Notwithstanding several crossings with inferior breeds this species has lost none of its original qualities; on the contrary the wool has become slighty finer and longer. The best breed is to be found in the neighbourhood of Tunja, Estate of Boyaca, which produces very beautiful, soft and fine wool, about a foot in length.

Oveja Nankin. Introduced into the country about the year 1869 from China. It is small, but is distinguished for its wonderful fecundity, the savouriness of its flesh; its wool resembling merino, colour bright yellow, soft, and quite equal to the indigenous species.

Oveja de Tierras Calientes. Very large, flesh delicious, fleece coarse and strong, staple from 6 to 8 inches in length. It abounds in the valley of the Magdalena, whence it can be easily and cheaply exported, and it can be raised on pastures quite unfitted for the rearing of cattle. Many millions of this discription of sheep could be raised on the Llanuras of Tobina, and on the banks of the Rivers Cesar and Magdalena. Some few Leicestershire sheep have been imported, and the result of their crossing with these indigenous to the country has been satisfactory.

Maise and sugarcane are now being weeded: the instrument wherewith the operation is performed is of the shape of an English hoe but larger, yet not quite so large as the *phaora* or *kodali* of India."

I have quoted the last paragraph to show that the soil and climate is somewhat akin to that of parts of India, and as the mangoe, guava, and plantain flourished, and ripen fruit, the imported breeds of sheep should thrive.

It would be easy to obtain seeds of the best description of grasses indigenous to Columbia, and their systematic cultivation and extension in the Punjab would very speedily convert large tracts of waste lands into valuable pasturages.

The natives of the Punjab perfectly understand sheep farming and goat breeding, hence trained men in numbers would be available as shepherds, and if Government annually imported 100 of the "*Bright yellow wooled*" breed of sheep for distribution, the "*Golden Fleece*" of the Punjab, when woven, would be highly prized by all classes and greatly enrich the native sheep farmers.

Letters were submitted—

1. From the Secretary, Government of Bengal, in continuation of former correspondence, on the subject of Manilla hemp, and intimating that some shoots thereof will be transferred for the Society's Garden on their receipt from the Andamans.
2. From Captain J. F. Pogson, suggestions as to the cultivation of *Sorghum saccharatum.*
3. From the Secretary, notice regarding cochineal.
4. From the same, remarks on sugarcane *quoad* its propagation from seed.
5. From the Secretary, Agricultural Society, Bijnour, a memorandum on the improvement of agriculture in the Bijnour district.

The above were transferred for the journal.

MINERALOGY.

Dr. Crown, who has just returned to Japan, reports that Corea is wonderfully rich in metals. He says that from Fusan to Genzanshin, or the Gold Mountain, a distance of 310 miles, the geological structure is not incompatible with the theory that the whole region is productive of the precious metal.

FORESTRY.

THE PROFIT OF CASUARIAN A CULTIVATION.

I SHALL suppose that five or six acres of ground are available in the neighbourhood of the reader—it matters not where he may be—perhaps in Tripasore perhaps in Madras, or it may be in Salem. The land need not be very good, common waste land will do very well. I shall also presume that the reader does not care of risk much. Then let ten negihbours club together. If you read this article through you will see how, for a very trifling outlay, a large return may be obtained in three or four years. To begin from the very beginning. Purchase 12lbs. of casuariana seed from Madras. The cost will be Rs. 6. Sow it in 24 small beds 10 feet long and 5 wide. Sow on the surface and cover slightly with the fine soil and well-rooted manure; some cut straw being spread over the beds to protect the seedlings from the sun. Each bed will produce about 1,000 plants. It is calculated that the 24,000 plants will cost at the outside Rs. 48. To save the trouble and uncertainty of raising them from seed they can be purchased for Rs. 5 a thousand, *i. e.*, Rs. 120 for 24,000. Having got the plants transplant them on cloudy days. The land should be prepared to receive them in the following manner. Plough twice, harrow and ridge. Let the ridges be 2 feet apart. Plant the seedlings on *alternate* ridges and let each be 3 feet in front of the other. Thus each plant will have 12 square feet. Water immediately after transplanting. The cost of transplanting will not be more than 12 annas per thousand plants. The ridges between the lines of casuarianas should be sown with castor oil beans. These will soon germinate, and as they grow up will afford shade for the young casuariana and the sale of beans ought to cover the expense of watering for the first year. Casuarianas should be planted from each other at the distance specified and then only will they grow upright, if too far apart the main stem is liable to fork and produce many side branches, thus considerably reducing the value of the tree. The trees will need to be watered only for the first year. It is estimated that under very unfavourable circumstances as much as Rs 100 per acre will be required for the first year. In preparing the following estimate, two rules have been observed, first to cultivate all outlay at the highest possible rate, and all income at the lowest. Land for casuariana cultivation may be had at Rs. 10 an acre. I shall put it down at Rs. 20 to be on the safe side.

A casuariana tree 4 years old will fetch as it stands not less than one rupee. I shall value it at 8 annas. The profit from the castor-oil beans are left out altogether. Here then is the cost of raising a plantation 6 acres in extent for four years.

	Rs.	A.	P.
24,000 plants at Rs. 5 per 1,000	120	0	0
Ploughing 6 acres at Rs. 3 per acre	18	0	0
Planting and first watering at as. 12 per 1,000 ...	18	0	0
400 cart loads of manure at 8 as. per cart	200	0	0
Watering for first year	600	0	0
Cost of watching and all sundries, say	444	0	0
Total ... Rs.	1,400	0	0

Each acre will contain 3 630 plants—allowing 12 square feet for each Supposing one-sixth dies away we have left 3 0 0 per acre.

	Rs.	A.	P.
Sale 3,000 x 6=18,000 plants at 8 as. each ...	9,000	0	0
Deduct gross expenditure	1,400	0	0
Net profit ...	7,600	0	0

or a return of 550 per cent. !

Now if ten persons shared expenses the risk of each would be Rs. 140 at the utmost, and the profit 760. If Rs. 140 be put by in a bank the most one will get in 4 years will be 20 or 25 Rs.—*The Kurasi n and Anglo-Indian Advocate.*

B.

THE CAMPHOR FORESTS OF SUMATRA.

THE Chinese here are doing a good business in benzoin, gutta, rattans, and camphor, which are brought down in great quantities by the independent Battaks from their forest-clad mountain, and which are to this day mostly exported to Singapore, without there being any bother about customs export duties; buffalo hides, in which, however, the transactions are few, being the only article

subject to an export duty. The Battaks bring the three first-named valuable articles in plaited rattan baskets, which they carry slung from the extremities of a bamboo laid on the shoulder. As return freight, they bring away from this much salt and other necessaries. The appearance of the Battaks I saw here was not particularly pleasant, and they excited my antipathy, especially from the circumstance that actually, though to a limited extent, they are cannibals. The camphor of Baros is renowned throughout all Netherlands India, and has given its name (*Kapur Baros*) to all sorts of this article of trade. It distinguishes itself by its peculiar strength and a relatively trifling amount of volatility. Under similar conditions a given quantity of Baros camphor loses by evaporation only a fourth part of its weight, in the same time that as large a piece of Japan camphor wholly evaporates. Hence the former is an article in great demand, and brings high prices. Not unfrequently Baros camphor is sold at Singapore for 10,000 guilders per picul. Especially amongst the wealthy Chinese there it is greatly in demand for embalming the bodies of their relations whom they intend to send to China for burial in their native land. It is found in small crystallised pieces and thin layers amongst the fibres of the camphor wood, and is usually offered for sale in that condition, after removing the coarser woody articles and other foreign matter. Trees containing a very considerable quantity of this costly product are comparatively rare. Most of the camphor trees contain it in such a thinly distributed condition that it can be only extracted by boiling as is the case with the Japan description. The Battaks are very skilful in finding out trees abounding in camphor, and dislike the slow boiling process. They, too, desire greatly to earn as much money as they can in the shortest possible time, in order afterwards to enjoy a longer rest. In Sumatra, camphor wood is not only used for making the boxes by which many persons who have returned to Europe are recognised there, when travelling, as being from the East Indies, and according to which are determined the prices they have to pay at lodging-houses, &c., but also as timber. That people are not sparing with it is apparent from the fact that the great bridge over the Batang Taro river, now under construction, is wholly made of this wood. Although not particularly hard, it is of great use for building purposes, because many species of insects—the white ant being the most dreaded, which in these districts manage to destroy all other kinds of wood with wonderful rapidity—leave the camphor wood untouched. The smell of camphor is plainly perceptible in the chips which fall off on preparing the wood, and even in the leaves, though not very strong, when rubbed small.

It is a pity, however, that the natives living in the midst of this bountiful gift of Nature are using it up so carelessly, that, if they are not in time brought under control, an end will soon come to this productiveness. At present the dense forests of Battak Land still contain hundreds of thousand of camphor trees, but the Battak cuts away recklessly, without a thought of the future, and without planting fresh camphor trees. In the same way an end will soon come to the present large stock of gutta in the Sumatran forests. What is found most abundantly in these districts to the east of Baros and Singkel is the valuable benzoin, that fragrant gum which is utilised for incense and other scents. I saw astonishing quantities of it in the Chinese warehouses at Baros. In hundreds of cases this article is shipped to Singapore—that centre of the trade of the Far East. The benzoin is bought unprepared, from the Battaks, usually at 1·40 guilders per catty. The scent of this gum is very agreeable, and it is a pleasure to stay in the storehouses, where it is sorted and then carefully packed, after being plentifully sprinkled with water. Remarkably enough, the Battaks take great care that other benzoin trees shall rise up to replace those cut down; for in fact, they have nothing else to do than to burn the stumps and scatter the seeds in the ground. The planting of gutta and camphor trees appears to require more trouble and care—more, at least, than is compatible with human labour and duty in the opinion of the Battaks.

THE GARDEN.

THE importance of fruit as a means of obtaining an income, is not properly appreciated. We grow fruit for pleasure and as a curiosity, whereas few crops pay so well. In various parts of America, this crop is securing more attention, and in California, especially, it has assumed vast proportions.

ROSES.

Roses in Pots; their Summer Treatment.—These are often sadly mismanaged by amateurs during the summer and autumn months. They are as a rule kept too long under glass, the circumstance of their being in pots appearing to suggest to their owners that they should have the protection of glass also. Instead, however, of keeping them in the greenhouse after they have done flowering, they should be placed out of doors in the full light of the sun, but in such a position as that they will be protected from cold winds. If the pots can be plunged to the rims in coal ashes, with a depth of an inch and-a-half or two inches of the same material between the bottoms of the pots and the soil below, it will be better for the plants, and save much trouble in watering. Liquid manure should be applied twice or thrice a week, always in a clear state and weak, and never when the plants are very dry.

They should have plenty of room, so that light and air may circulate all round them. Don't prune them to any extent, as is very frequently done mistakenly by amateurs when the plants are turned out of doors, but let them finish the growth that may have been commenced under glass. It will be time enough to prune when they are to be placed in heat in winter time with the view of starting them into growth for flowering. In the month of September, however, they should be drawn from the plunging material, and every plant turned out of its pot with the object of ascertaining the condition of the roots and the drainage. They should be treated as they appear to require on examination. Should they be pot-bound, either shift them into larger pots in good compost, or shake them out of the old soil, and re-pot in the same sized pots, if it is undesirable to increase their size. Whether they are potted or not, let the condition of the drainage have especial attention; nothing is so certain to lead to ill-health and failure. Stagnation at the roots is the worst condition in which a rose can be placed. After potting they may be placed in the same position as before, only they need not be plunged—indeed, had better not be plunged—because there would then be less control over the watering, which is apt to be overdone after the rains of autumn become frequent. Pruning should not be done till the plants are to be started into growth for flowering, which may be any time during the winter, according to the convenience at command. They should be protected in cold frames after frost is anticipated, up till the time they are to be brought into heat.

Roses Mildewed.—This disease on roses is more than usually prevalent this year, no doubt owing to the weakening effects of the long and severe winter on such plants as have survived it. The present will altogether be a very unsatisfactory year for rosarians, but they must make the best of it. Various remedies may be applied; the best decidedly is flowers of sulphur dusted on to the affected leaves carefully, while the dew is on them in the morning or after they have been moistened with the syringe. A more cleanly and less objectionable way to apply sulphur is first to mix with every pound of it one-half pound soft soap. Thoroughly stir them together, and leave them in a tub or basin during the night, or for a few hours, when boiling water should be applied in such quantity as to reduce the mass to a liquid condition, so that the plants may be syringed with it. Use this liquour frequently, and your roses will soon regain a healthy, clean appearance. There is a little more trouble entailed in the use of this compound than in the use of flowers of sulphur alone, but the result is as satisfactory, and the plants never present the appearance of having had the meal bags shaken over them; there is no sediment left worth speaking of by the syringing process.

Cuttings of Roses; how to treat them.—Those who have roses in pots, and who wish to increase them, may do so freely now. The facilities wanted are either a cold frame or a handlight placed in a somewhat shady place. The best cuttings are those with a heel to them, that is, such as are short joined, and of themselves also short, but taken off their full length along with the thickened connecting part in junction with the main branch from which they spring. The base when taken off should be carefully smoothed with a sharp knife, not so as to reduce it much, but merely to remove any portions on the surface and edges presenting rags or inequalities, the object being to obtain a thoroughly smooth surface, which is always most favourable to quick healing. The cutting need not be more than six inches long, and all the leaves may be cut off except the top one. The leading or growing point of the shoot should be cut away, leaving only firm wood. A bed of pure sand should be made in the frame, or handlight, four or five inches deep, overlaying a stratum of leaf mould and roughly broken loam of a fibrous, rich quality. Dibble the cuttings into the sand, leaving the upper bud and leaf only above the surface; make every cutting as firm as it can be made in sand as the work of dibbling proceeds, and place them rather thinly, that is, in rows about two inches apart and about an inch asunder, cutting from cutting in each row. Give a good soaking of water immediately after they are all dibbled in, to settle the sand about their collars; shut up the light close during the day, but leave a good chink of air on at night. Should the position in which the frame is placed be somewhat freely exposed to light, a little shade should be used during the bright hours of the day. If in a shady place, no shade will be required. If the cuttings are good strong ones, and the treatment carefully carried out, a fine batch may be ready for potting up about the middle or end of September; but they will require to be kept in a cold frame throughout the winter.—*N. B. Agriculturist.*

FERNS.

A HOBBY is a wholesome thing. It is probable that even crest, monogram, and postage-stamp collectors are happier than are their fellow-creatures who have no definite pursuit. The autograph hunter belongs to a higher order in the scale of humanity, for his accumulations are interesting to the biographer and the historian, and perhaps also to the student of character as well as to himself; but collecting autographs, unless all and sundry are welcomed and number be the object, cannot occupy any one's whole spare time. The antiquary of all collectors is generally considered to have the most absorbing pursuit, and his little weaknesses have been the theme of satirists. But the labours of a Grose and an Oldbuck are most useful, supplying as they do details for the ethnologist and the historian. The coin collector is another most useful species of hobby-rider for ancient history owes much to numismatology. But the study of antiquities of any sort is limited by the exhaustible nature of the field, and the fact that a discoverer often removes all he finds. But few can hope to make good collections and indeed the antiquary values the objects in his collection by their rarity, and were ancient implements and coins found in abundance they would cease to be prized. It is otherwise with the products of Nature. Their variety as well as their quantity is inexhaustible and although specimens of rare species are indeed cherished, a collection is valued greatly according to its completeness. Any one may take up the study of natural history, whether of the animate or inanimate creation, without fear of ever exhausting the subject, and sure of always finding something new to him. If he tires of one branch he can take up another; and indeed the study of one branch must often be incomplete without a good knowledge of others. Where would the practical geologist be if mineralogy were the only detail he had previously made himself acquainted with he; must have a certain knowledge also of zoology, conchology, and bot any. The students or even the amateur of any branch of natural science must be a happier man, or woman, than any mere crest or stamp collector.

To the resident in India, who either lives in a jungly district or can make trips to the hills, botany or even mere plant collecting, is—entomology perhaps excepted—probably the branch of natural history which offers the greatest facilities for study, and if he has already turned his attention to it at home, he must at all events look with interest at the new forms of plant life which present themselves to his view in this warmer climate. He will not indeed find his dreams of tropical luxuriance everywhere realised, but even in the most dreary tracts of the drier parts of India he will, in almost every ravine or patch of jungle, find something new and of interest. The present writer well remembers his delight at finding, before he had been a year in the country in a dry part of Bundelcund where few striking flowering plants were visible, the magnificent climbing lily, *Gloriosa superba*, luxuriating in the arms of the *Baer* (*Zizyphus*) bush and the interest with which he afterwards found the same plant growing on open "downs" near Almora in the Himalayas, and again at 5,000 or 6,000 feet lower level, near the seashore in Akyab.

But botany is a wide word, and no one can hope to be really a botanist without years of special study, not only in the garden and the field, but at the desk and with forceps and knife in hand, and lens and microscope at eye. A successful collector he may no doubt become; for a good eye, perseverance and physical endurance, are the chief qualities for that degree of attainment, and he may then soon qualify himself to the extent of being able to refer plants to their [illegible] natural [illegible] ... but [illegible] that is

quite a different thing! Not that we have the slightest wish to discourage anyone from the serious study of botany. All that we are now concerned to do is to point out one branch of the science which may be taken up almost quite by itself, and in which the amateur may do much as well for its advancement as for his own benefit; for it is one too often despised and neglected by the scientific labourer. Pterdology or the scientific knowledge of ferns, is perhaps the division of botany which at once requires the least preliminary knowledge and the least labour for its pursuit,it gives the most pleasure in the collection of specimens, and yileds the most lasting enjoyment. Full many a flower loses its beauty directly it is plucked or at least after it is transferred to the drying press but ferns are independent of floral attractions; and they always, if carefully treated, retain their beauty of form and not seldom of color in the herbarium. A fern is a thing of beauty and a joy for ever, while even the *Gloriosa superba*, above praised for its beauty in life, is good in the herbarium only for reference. A fern is not seldom beautiful as a whole plant; while each separate frond if intelligently gathered is perfect in itself and satisfies the eye. The want of a flower does not strikone in looking at a fern; its beauty is complete without it, and the proof of this is that specimens in ladies' albums generally want even the fructification which completes the plant, and is so often necessasy for the identification of the species. The beauty of form and cutting alone is sufficient for the fair collector, who is thus however very unfair to her collection.

If, as has been said above, the resident of a hill station in India is favorably situated for the general study of plants, he is most peculiarly favored if he makes ferns his speciality. In the whole of the British isles there are not (speaking without book) forty distinct species of ferns *Filicets*, and in the circuit of twenty miles round Edinburgh within which botanical students generally collect, there are only about twenty six species. But within twenty miles of a Himalayan station one hundred good species can easily be got, besides numerous well recognised varieties. In one walk from Mussoorie, when not collecting, the present writer has observed 32 distinct species of ferns, in about an hour's time. The latest authority on the ferns of Northern India—plains and hills together—Mr. C. B. Clarke admits 363 species and recognized varieties; while another writer, Colonel Beddome, makes the number in Northern India 405, and in all India 632. Sixteen new species are included in Mr. Clarke's list, and this fact together with the great difference in the totals admitted by the two authors, shows what a wide field for research and study still exists. Mr. Clarke admits 142 species, as being found in the Himalaya westward of Nepal 257 for Nepal and the Himalayas to the east of it, and 247 from Assam to Chittagong, besides 47 species in the plains north of the Peninsula, and 38 of the whole are peculiar to Northern India. If areas be taken, the 47 species of the plains of Northern India seem poverty itself when compared with the 40 or so of the British islands. But how few Europeans in Indian know that there is even one fern in the plains. They would be astonished to be told that the so-called real Maiden Hair grows in perfection in the Entally and doubtless other suburbs in Calcutta, and that it may possibly even be found in their garden wells in much drier parts of India.—*Civil and Military Gazette.*

FLOWERS AND THEIR SIGNIFICANCE.

THE language of flowers presents a poetical beauty which has tended to preserve their ceremonial use from the remotest ages of antiquity. These adornments of Nature have been conspicuously associated with the rites of marriage and burial, with the commemoration of the dead, the rewards of victory and the celebration of many national feasts and sacrifices of several nations. No people in modern times, if we except the aborigines of the Pacific islands, has evinced a more ardent passion for floral display than the natives of India, particularly the Buddhists, whose enthusiasm has led them to cultivate extensive gardens exclusively for the requirements of their temples. The Persian element, too, show striking instances of veneration to flowers, it having been recorded that the significance of these emblems is largely associated with their worship. It is, however, a remarkable fact that people of every creed and tongue are more or less thus devoted, and in the poetry of every country can be gleaned abundant traces of flowers supplying the most superb imagery. Such embellishments are to be found illustrating some of the finest conceptions that have been handed down and hallowed by tradition. England boasts of her emblematic rose, Ireland of her Shamrock, and Scotland of her Thistle, all meant to bear an expressive significance the sacred character of which still as prominently prevails. But it is throughout classical history and poetry that we find most enjoyment on this subject. The Greeks and Romans like the Astecs dedicated particular flowers to individual deities. We know that the Narcissus belonged to the mighty goddesses; the poppy was also sacred to Ceres; Venus had her anemone; Hera, the lily; Artemis, the myrtle, and Sappho crowns the Muses with Pierian roses. As rewards for victory, the Romans certainly surpassed every nation in the number and variety of their chaplets, as no triumph seems to have been complete without a plentiful use of flowers, the *florum foliorumque sparsio*, but though the Greeks were thus surpassed, they were not dead to the signifiance of flowers on such occasions, as we learn that Brasidas, when he was proclaimed the liberator of Greece, was publicly crowned with a crown of gold, but individually they decked him with *garlands*. It is hard to assign any year or period when the use of chaplets at meals or rather at the *symposia* was first introduced, but we learn that at Rome and Athens the flower-sellers and chaplet-makers had an extensive trade,—at the latter place a quarter of the market being devoted to them. At marriages the wreaths were composed of myrtle or verbena, and the flowers were plucked by the bride herself, as the purchase of flowers for the purpose was an ill omen. In modern times the myrtle for the bridal wreath has been displaced by Orange Blossom, the signifiance of which has puzzled some of our professed informants. The bridegroom's *coroner nuptialis* was generally formed of verbena while the doors of his house and the bridal couch were made gay with garlands. Customary as it is for us to place flowers on the graves of the departed, and bedeck their biers with wreaths, there is not that significance attached to the ceremony and its purpose that rested so vividly in the hearts of the ancients. From Anacreon, it would appear that the rose was thought to possess a peculiar virtue for the dead and the springing of this flower from the tomb of the dead was welcomed as an earnest of their happiness, and it was the universal wish that the tomb-stones of departed friends might be light to them, and that a perpetual [illegible] of all kinds of sweet flowers might encircle their graves. Superstitious as these notions may appear to us, they suggest a sublimity which throws a charm around the ceremonial use of flowers.—*Deccan Herald.*

TEA.

OF course not only would tea be welcomed, but cotton goods, the demand for which beyond our frontier has grown with the increase of our own means of connection in India with the frontier.

THE price of brick tea on the Kumaun-Thibet frontier is not known with accuracy; but its price on the Kumaun frontier must be very much in excess of what Kumaun planters could supply it for. What the Thibetans at present consume is the "merest refuse," consisting of little else than the twigs and brushwood of the tea plant, and vastly inferior to the very sweepings of Indian tea godowns. The tea-planting industry of Kumaun would benefit largely by the opening out of a trade which would enable it to dispose of its coarser produce easily and cheaply. So heavily is Kumaun tea handicapped by the expense of transport to Calcutta, that the most profitable portion of the trade even now is that transacted in green teas with merchants from Central Asia, who purchase the tea at the factory and carry it away themselves, saving the planter the expense and trouble of packing. Kumaun planters are well aware of the advantages which a trade with Thibet would give them, and a former manager of the Kousani Tea Company actually manufactured brick tea, and endeavoured, but unsuccessfully, to get it into Thibet. Lastly, the Bhotias, in whose hands to Thibet trade lies, would derive great benefit from the substitution of a new article of commerce for borax, the price of which has fallen under American competition too low to afford substantial profits on its import.

WE hear a good deal just now about removing the tariff barriers to English commerce with France and other countries. It would be a lucky thing for tea enterprise in Northern India if the engineer, with or without the help of the soldier, could push his way beyond the border. There is, remarks the Government of the North-West Province in its report on frontier trade, a fine market for Indian tea in Thibet; but, unfortunately, the markets of that country are closed by the united efforts of the Chinese Government and the Thibet Lamas, who, having the monopoly of the wholesale and retail tea supply of the country, are naturally averse to the competition of a traffic in Indian tea which might be more difficult to engross. This strict monoply is described in a recent report by Mr. Baber, H.B.M.'s Consul at Chung Ching; his remarks which specially relate to the prospects of a tea trade between Assam and Thibet, apply no less pertinently in the case of Kumaun, and the result of the system which he describes is that during the year under report not only was no tea exported to Thibet from the N.-W. P., but Chinese tea was actually imported into native Garhwal by the Nilang Pass. "Tea," Mr. Baber writes, "is to the Thibetan more than a luxury; it is an absolute necessity," yet the Thibetans on our frontier are compelled to purchase tea of atrocious quality, the price of which has been swelled by a long and difficult transport from the eastern extremity of the country; while immediately across the frontier there are tea gardens whence they could be supplied with a better article, at a cheaper price, and with profit to the Kumaun tea planters as well as to the itinerant traders (Bhotias) through whose hands it would pass.

FROM a return published by the London Tea Brokers' Association, we learn that the amount of Indian tea delivered last year was 43,807,000lbs. Though the total entered for home consumption is not separated from the whole importation, we presume that the above quantity represents it, as the imports were two million pounds in excess. Presuming that we are correct in this surmise, the sum contributed by the Indian tea planters to the revenue of the United Kingdom comes to £1,095,175, and we think that the Indian Tea Districts Association in London should press this upon the notice of the Secretary of State, with the view of some portion of it, if not the whole, being set aside for the guaranteed interest on those lines of railway in process of projection in and towards the tea districts. The appropriation of this money (yearly

increasing) need but be made for a short period, for the lines necessary could all be made in one decade, and the immense benefit all concerned would derive from their completion is self-evident. With facilities for free immigration to Assam, Cachar, and Sylhet, a development of the natural resources of those districts would lead to a large increase in the revenue. There would also be great military and political advantages, for it is manifest that sooner or later our relations with the Court of Mandalay and also with the border tribes that owe nominal allegiance to King Theebaw, must be placed on some more satisfactory footing than they are on at present; and we have had within the last twenty years numerous instances of the disastrous results of neglecting to place those outlying provinces of the Empire in rapid communication with our military base. We presume the cost of the numerous expeditions undertaken against the N.-E. frontier tribes is duly pigeon-holed in the Foreign Office, and now that money is to be had on favorable terms, it might be interesting to compare this ugly item of expenditure with what a line or lines of rails would amount to. We are assured from London that Indian tea has now taken its place in public favor, and may reasonably look for a large increase in the duty thereon; and it is surely not too much to ask that this money, contributed by an enterprise that has been established in the teeth of opposition both in this country and at home, should be temporarily devoted to fostering it. If guaranteed interest at 3½ per cent. were made from this fund, in eight years a network of railway communication would be carried throughout the Assam Commissionership, that would treble the present revenue, and throw open the iron, coal, lime, and vegetable productions that now remain practically locked up. Letters that appeared in our columns last year indicate pretty well the outlets for a trade in piece-goods and other manufactures that safe and rapid communication would engender, and we think the Chamber of Commerce might well discuss the matter with a view of inducing the local Government to duly represent it at Westminster.

THE CABUL TEA TRADE.

FROM a report on the Peshawur tea trade with Cabul and Central Asian countries, it appears that from October 1880 to January 1881, 2,144 maunds of Indian tea and 7,910 maunds of China tea were exported from Peshawur. These figures include the whole of the tea exported over the frontier in the direction of Cabul and Bokhara. It has been ascertained that by far the greater proportion of the tea exported from Peshawur is consumed in Bokhara. From October 1880 to January 1881, Peshawur merchants have sent to Bokhara—

3,288	maunds	of green China tea.
2,069	do.	of black China tea.
602	do.	of green Almora tea.
198	do.	chura Almora tea.
262	do.	of Putta Almora tea.
13½	do.	of black Almora tea.
524	do.	of green Dehra Doon tea.
118	do.	of Putta Dehra Doon tea.
30	do.	of green Kangra tea.

In Bokhara Proper, green China tea is in great demand. China Lonka is of three qualities—

No. 1 is bought in Peshawur	at Rs.	119	per md.
,, is sold in Bokhara	,,	147	,,
No. 2 is bought in Peshawur	,,	112	,,
,, is sold in Bokhara	,,	145	,,
No. 3 is bought in Peshawur	,,	108-8	,,
,, is sold in Bokhara	,,	136-8	,,

There is a class of China tea known as "kazaz" which has been from time to time imported to Bokhara from Russia. Persons who have long resided in Bokhara say that this tea is bought in Russia at Rs. 40 per maund, and is sold in Bokhara at Rs. 76 per maund. The road is now closed to this trade, but these figures show how far Russian merchants can compete with the Indian trade.

Black China tea is not drunk to any great extent in Bokhara, but finds a market in Khokand. It sells in Peshawur at 6 annas per lb. Bokhara is the central mart. The Indian teas are exported thither, but for the most part are at once bought up by merchants from Samarkhand, Tashkend, Khokand, and other outlying places, and are consumed in those countries.

Of Indian teas, Lonka from Almora, Dehra Doon, and Kangra sell at Rs. 77 per maund; from the trade returns it appears that the price per maund in Peshawur is Rs. 60.

The merchants in Peshawur are of opinion that there is an increasing demand for Indian green teas. Some Indian black tea was sent by one merchant as an experiment to Bokhara, but the tea did not meet with approval; this may be due to the fact that the Indian black tea was of the 2nd and 3rd quality, the heavy price of the first quality rendering its export unprofitable.

The average journey to Bokhara takes from three to four months. Merchants bound for Bokhara do not seek for a market on the road. It entails trouble to unpack their goods; they start with the fixed intention of bringing back Bokhara silks and gold, and are sure of a certain profit.

The route from Cabul runs by Bamian, Saighan, Doaba, Heibak, Hasrat, Sultan, Khulm, Balkh, Kileffort, Karshie to Bokhara.

The market in Bokhara is most uncertain, and there is a singular want of concert among the exporting merchants. The market is frequently over stocked, and the smaller men come back with heavy losses. At the present time, out of eleven merchants who have traded to Bokhara with teas, seven declare that they can no longer trade with profit; that it is all a matter of luck.

The daily consumption of teas in Bokhara, including the outlying countries, is said to be 80 maunds; in Cabul 6 maunds; in Jellalabad 2 maunds; in Peshawur 5 maunds.

From this it will be seen that the consumption of tea in Cabul is insignificant as compared to that of Bokhara, and all merchants connected with tea agree in saying that Cabul will never afford a large market for the sale of teas.

From the books of Peshawur merchants it appears that from October 1880 to January 1881, 82 maunds of green China tea, and 36 maunds of black China tea have been sent to Cabul; and 296 maunds green Almora tea, 151 maunds green Dehra Doon tea, 7 maunds putta Dehra Doon tea, and 30 maunds green Kangra tea.

The greater part of the tea consumed in Cabul is exported thither by Cabul merchants.

China Lonka of the first quality is by far the most popular of teas, as it is the most expensive, and all classes in Bokhara will stint themselves in many of the necessaries of life to indulge in this luxury. A saying has almost past into a proverb in Bokhara that "a man drinks tea or dies," and it is clear that Bokhara and the neighbouring countries will always be a great and increasing market for teas.

TEA PRODUCTION IN JAPAN.

THE industrial resources of Japan have received considerable attention of late, and trade generally in that country appears to have developed to a noteworthy extent. In a report on the products of the island of Kin-Shin, Southern Japan, it is stated that the soil produces, with little attention bestowed upon it, two crops of cereals, while rice, tea, and tobacco seem to be indigenous. The production of tea for export to foreign markets in the island of Kin-Shin amounted, some five years ago to about 25,000 piculs annually (a picul is 133⅓ pounds). The low prices ruling in 1876 and since then, to a certain extent, discouraged the cultivation of tea on a large scale, and many plantations were neglected for more profitable pursuits, so that now though its cultivation is in more favour, the total production for the year 1880 is only estimated at some 20,000 piculs. Out of this quantity about 7,000 or 8 000 piculs, reach Hiogo and Yokham directly, which are large local markets, and where it is used for mixing with the tea of those districts. The principal tea-producing districts of the island are Chikugo, Hio, Bingo, and Ourishima adjoining and in the neighbourhood of Nagasaki. From Chikugo some 6,000 are exported, of which about 4,000 piculs go direct to Osaka for the Hiogo market. The balance of 2,000 piculs is shipped from Nagasaki, the greater portion to North China. The Chikugo teas are in many respects the most suitable for export to the United States, being similar in quality, &c., to the teas of the northern or middle part of Japan, which are known there; for this reason, too, they are very desirable for mixing, and the consequence is that the greater portion of the production finds its way to the larger ports for this purpose. The teas from Chikugo are usually shipped from Hakata, an unopened port in native junks to Osaka or Nagasaki. Adjoining the Chikugo district is that of Bingo, which produces about 3,000 piculs, the most of which is shipped in junks from an unopened port to Osaka. The Hiogo district produces some 6,000 piculs, which nearly all goes to the Nagasaki market. Ourishima produces about 2,500 piculs. Some of this is exported to Tien-Tsin, in China; the better qualities are the finest teas grown in Kin-Shin, but being of a very curly appearance, not unlike the green teas of China, they do not find a ready sale in the United States. In Canada, however, this leaf is more popular, and is exported thither in large quantities. With regard to the preparation of teas the process is, generally speaking very simple. The native women commence picking, the young leaves from the plant, which is an ever green, about the beginning of May. The leaves are then placed on mats and rolled for some time by hand, until they assume a curled-up appearance, and are then either dried in the sun or gently fired in iron pans till dried sufficiently to prevent them from spoiling. The teas are then packed in straw bales of about sixty catties each, and sent to market for sale. When purchased by the tea merchants, who have large buildings and arrangements for the purpose, the tea is subject to a careful firing in iron pans, with charcoal fires, for a

period of from one to two hours, during the whole of which time it is incessantly stirred by hand. This process takes out all the moisture from the leaf, causes it to be more compact and improves the colour. Immediately after picking, the leaves are placed on linen or other cloths above a vessel of hot water, and steamed for a short time. They are then very carefully rolled, while still moist, by hand, till they are well twisted, and then placed on large sheets of paper in wooden trays over charcoal fires until they are thoroughly dried, then packed in boxes of about fifty catties to the picul and sent down for sale. The process after reaching the tea merchant is exactly the same as described for poorer teas.—*The Grocer.*

THE *GLAMIS CASTLE* TEAS.

OWING to the statements published as to the bad quality of some Chinese teas brought here recently by the Torres Straits mail steamer *Glamis Castle*; the Attorney-General requested the Central Board of Health to look into the matter, and ascertain whether such teas were fit for human consumption. The board consequently obtained some samples which Mr. R. W. E. MacIvor, analytical chemist, who is a member of the Board, spent some time in examining. He found that such samples did not contain any mineral substances absolutely noxious, but that many kinds of foreign leaves and stems—that is to say, leaves and stems not of the tea plant—were comprised therein, and he pronounced the stuff to be unwholesome.

At a meeting of the Central Board of Health held on Monday afternoon (Drs. Youl, Clarke, and Hardy, and Mr. MacIvor being present), Mr. MacIvor's report was received, and it was resolved to communicate its tenour to the Law Department, and to recommend that the spurious teas be destroyed.

We have been favoured by Mr. Frederic Dunn, senior assistant to Mr. J. Cosmo Newbery, of the laboratory attached to the Industrial and Technological Museum, with the result of analyses of two samples of the Chinese teas, ex *Glamis Castle*, recently sold at auction by Messrs. Fraser & Co. It may be mentioned here that genuine tea on analysis gives the following results :—Ash, from 4 to 6 per cent.; soluble salts, between 3 and 4 per cent; extract, from 32 to over 50 per cent.; and theine, from 1½ to 2½ per cent. Both of the samples analysed by Mr. Dunn were from bulk lots. The first was from a lot sold at 3½*d.* per lb. in bond, and yielded the following percentages :—Ash, 6·25; soluble salts, 2·45; extract, 27·00; theine, 0·56. The second sample, which was from a lot that realised 4*d.* per lb. in bond, gave the following results :—Ash, 6·60 per cent; soluble salts, 2·48; extract, 24·00; theine, 0·75. Mr. Dunn further informs us that it was very difficult to find a perfect and genuine tea leaf in the samples; and that the stuff consisted for the most part of decayed, exhausted, or foreign (other than tea) leaves, foreign stems, tea sweepings held together in little nodules by starch paste, and pieces of bark, husk, and nutshells. All this rubbish was faced with plumbago to give it a black appearance; and was totally unfit for dietary purposes. The preceding figures show that, except in the matter of ash, the *Glamis Castle* samples were very deficient in the constituents of which genuine tea is composed. Probably the high percentage of ash is attributable to the presence of the tea-sweepings or dust.

Messrs. Dalgety, Blackwood & Co., send us the following report :—

"6 Hanover-street, Fitzroy, June 13, 1881.

"Gentlemen,—I have the honor to submit to you the following report on the four samples of tea sent to me for analysis.

"The three samples of black tea Nos. 1, 2, and 3, yielded by incineration normal quantities of ashes, namely :—No. 1, 5·6; No. 2, 5·3, and No. 3, 5·5. Therefore, the common adulterants, such as alumina, chromate of lead, sulphate of copper, cyanide of potasium, gypsum, lime, and magnesia were not indicated. Neither could I detect any of them by the application of chemical tests or by the microscope.

"The sample No. 4, on the other hand, left 22 per cent. of ashes. From this result it is evident that 16·5 per cent. of spurious substances are present, which I found to consist of clay, tumeric, and Prussian blue.

"I am also determining the amount of theine in each sample, and shall hand in my report without delay,—I am gentleman, yours faithfully,

"JOHN KRUSE, Analytical Chemist.

"Messrs. Dalgety, Blackwood & Co., Melbourne."

Accompanying Mr. Kruses report was the following memorandum :—

"The Nos. 1 to 3 refer to the samples of teas mentioned in the press and in Parliament as being objectionable, but on being analysed they prove to be free from adulteration, and not at all injurious to health. The No. 4 is the sample of 180 quarter-chests tea purchased on the 20th ultimo by a gentleman who has made himself prominent in bringing this matter before the public, the analysis, on the other hand, showing that tea is not only adulterated, but deleterious to health."

Attention was called to the recent public sales of damaged teas by Mr. Anderson in the Legislative Assembly on Tuesday, and some further information was given by the Attorney-General as to the action of the Law Department. Mr. Vale hoped that members would not be over-sanguine as to the results of the steps he had already taken. Samples had been obtained both of the tea referred to last week by Mr. Bowman and of the shipment mentioned in the *Argus* of Monday, and if it was in the power of the department to cause the destruction of unwholesome teas that would be done. Mr. Bowman availed himself of the opportunity to answer the question put to him by a correspondent of the *Argus*, as to what he had done with 180 quarter chests tea he bought on May 26. The hon. member said that if it was the gunpowder tea that was alluded to, he did not complete the sale, but passed the purchase on to another buyer. The price was 8½*d.* a pound in bond. Gunpowder was artificially coloured with Prussian blue and gypsum, and allowed to be sold in London, where there was an adulteration act in force. The hon. member mentioned the name of the firm by whom the *Glamis Castle* tea was imported and also some of the buyers. Mr. Francis pointed that it was unfair to speak of any firm as importers of tea of this kind, because cargoes were oftener sent here to be sold on commission than imported by firms on their own account. As a matter of fact the teas received by the *Glamis Castle*, and the same may be said generally of shipments of tea, were not "imported" by any Melbourne firm, but were sent here as a speculation by shippers in China. In addition to the facts mentioned in the House, we learn that the Central Board of Health on Tuesday caused some samples of tea imported in the *Ocean*, in Cleves bond, to be examined. It was decided that the tea is unwholesome and ought to be destroyed. Steps have been taken to stop the sale of this compound, as well as that of the consignment ex *Glamis Castle*. With regard to the portion of the *Ocean's* cargo purchased by Mr. Bowman, we learn that an analysis made by Mr. MacIvor, for the Central Board of Health, shows that the tea is greatly adulterated. It is faced with Prussian blue, and is full of iron filings, earth and other foreign substances.—*Australasian.*

COFFEE.

INOCULATION PROCESS WITH CARBOLIC ACID.

(*Concluded from page 244.*)

DOTELOYA ESTATE.

Operations on a few trees only.

OBSERVATIONS on the fruiting of healthy pin-spots. On treated coffee trees, none fruited; most dried up and turned brown. Untreated coffee trees—83 per cent. fruited.

Results examined by Messrs. James Blackett and John Drummond and testified by James Blackett.

12th December 1880.

Bellongalla Estate.

Operations on one acre. Observations on the fruiting of healthy pin-spots specially marked for observation. On treated area—87 per cent. did not fruit, most dried up, 13 per cent. had thrown out a few isolated spores. On the adjoining untreated area—all the pin-spots had fruited, additional pin-spots and already developed spore patches had formed.

General Observations :—Progress of disease on treated area decidedly checked; progress of disease on untreated area at the end of ten days about 300 per cent.

Results examined and testified by Alex. Thom.

28th December 1880.

Extract from letter to myself :—"I certainly think the trees which have been inoculated are freer of leaf-disease, either in the pin-spot or red rust stage, than the adjoining untreated area, but so far I cannot say that the inoculation of carbolic acid has *eradicated* the disease."

W. D. GIBBON.

5th January 1881.

Moragalla Estate.

Observations on the fruiting of pin-spots :—No effect of treatment observed on old shuck trees, nearly all pin-spots fruiting. On the main area treated, not one of the pin-spots fruited, spots turning brown.

Results examined and testified by Mr. Geo. Sloan Paxton.

29th December 1880.

Fairieland Estate.

Observations on healthy, specially marked pin-spots. Treated area—In no *single* instance had any of the pin-spots thrown out any spores. The pin-spots themselves had turned brown and were pronounced (and in this all were guided by Dr. Thwaites' decision) to have been injuriously acted upon.

Untreated adjoining area—In *nearly every* instance had the pin-spots on this area thrown out spores, a few only had not done so.

Results examined by Dr. Thwaites (late Superintendent, Botanical Gardens), Messrs. Anderson, Dewar, and Pyper, and testified by

J. LEWTHWAITE DEWAR
and GORDON PYPER.

13th January 1881.

Roseneath Estate.

Observations on pin-spots; treated area—22 per cent. of pin-spots fruited the rest did not.

Untreated area—76 per cent. fruited.

Result examined by Messrs. Anderson, Dewar, and Pyper, and testified by

J. LEWTHWAITE DEWAR
and GORDON PYPER.

13th January 1881.

Sufficient evidence being now collected to establish that the checking of the progress of the disease as evidenced by the non-fruiting and the dying off of the pin-spots, in the treated area, was due to the treatment and not to accidental natural causes, comparative minute observation on adjoining untreated area, except broad comparison as to the prevalence and state of disease and general appearance of the coffee, was considered by me not further necessary.

Pallekelly Estate.

Observations on healthy, specially marked pin-spots out of 183 pin-spots, only 11 had thrown out a few isolated spores which looked pale and unhealthy. Nearly the whole of the pin-spots had been affected and had turned brown.

Results examined by Messrs. Vollar, von Kriegsheim, and Gibbs, and testified by Mr. H. J. Vollar.

14th January 1881.

Peradenia Estate.

Inoculation followed upon the 4th day by vaporization. Observation on healthy pin-spots and bright orange coloured rust patches. "No single pin-spot" on the marked leaves had thrown out spores, large majority showed a brown patch in centre, and were to all appearance dead. Bright spore patches had turned brown and most spores grey, a few only retained orange tinge.

Results examined and testified by Mr. G. Ross.

15th January 1881.

Following I give now in the first instance the history, almost up to date, of the area that had been treated early in January last, on Pallekelly and Peradenia estates, by the process I have finally recommended, *viz.*:—

THE VAPORIZATION PROCESS.

With carbolic acid temporarily absorbed and bound by a dry powder.

Pallekelly Estate.

As it was here for the first time, that I tried the above process, I selected for the operation as heavily a diseased field as I could find, paying particular attention to obtain for the experiment healthy and vigorous fungus, so as to eliminate all danger of wrong conclusions. The field was heavily diseased, The disease was at its height, and in the centre were about 20 shuck trees in a bare patch, the foliage of which was at the time simply one mass of fruiting fungus, and which would come under the classification of chronically diseased trees.

I.

Observations made on the 8th day after treatment. Out of 104 marked pin-spots that presented every appearance of health and vigour before treatment, only one spot had thrown out an unhealthy looking isolated spore. The rest in nearly every instance had turned brownish and appear to be dying off, Bright orange spores and spore patches: 30 per cent. of these have been injuriously affected, the spores having lost all colour and patches have blackened. 21 per cent. are fading; the rest of the spores still maintain a bright tinge but patches by blackening in most cases. From the general appearance of the field, a decided check of the progress of the disease is discernible. Results examined by Messrs. Vollar, von Kriegsheim, and Gibbs, and testified by Mr. H. J. Vollar.

14th January 1881.

II.

"At Mr. Schrottky's request, I have gone carefully over the field of coffee treated under his direction, a month ago, by vaporization and which had two applications. The last was three weeks ago.

"To what I reported at the time about the result of the treatment, I can now add that I see no bad results. The coffee is throwing out new wood, which looks perfectly healthy, not even the tenderest bud having been injured by the vaporisation. The field was heavily diseased at the time of application, and certainly looks much better now: though I cannot say that the disease has been eradicated.

"I can see no unusual fall of leaf, and comparing it now with the adjoining coffee untreated, its general appearance is decidedly better."

H. J. VOLLAR.

5th February 1881.

III.

"From what I have seen of the experiments, I fully agree with what has been said (the above) by Mr. Vollar." This addition authorized by Mr. R. B. Tytler.

IV.

"I have much pleasure in stating that on close examination of the field that was treated by your process of 'vaporization,' some three months ago, I find that it compares very favourably with the adjoining untreated coffee. On the latter, leaf-disease is again showing up, while on the treated area it was difficult to find a leaf diseased."

H. J. VOLLAR.

9th April 1881.

N. B.—This part of the estate was suffering to some extent from a fresh attack in March, while I was in India. There is no indication of the treated field having suffered to any appreciable extent.

E. C. S.

V.—"The field treated in January and with a couple of subsequent applications has kept remarkably free from disease. With the exception of one tree, now badly diseased, the field is almost entirely free of disease. The shuck trees that were in January full of disease have been keeping and are still without disease."

H. J. VOLLAR.

31st May 1881.

Peradeniya Estate.

Here as well I selected fields that suffered from the disease in a pronounced and vigorous form, and I rejected several fields proposed by Mr. G. Ross, as I did not consider them sufficiently diseased to enable us to judge correctly of the results. In fact, we had some difficulty here in finding a field sufficiently diseased for the purpose.

I.

A four acre field first inoculated, then vaporized, in the usual way.

Observations made on healthy pin-spots and bright orange-coloured spore-patches:—Not a single pin-spot fruited. The spore-patches had almost all died. The patch had turned brown and the orange spore grey. A few only still showed a faint orange tint.

A one acre field; only vaporized but with three applications within ten days, one of unusual strength,

Results much the same as above. No pin-pots had fruited, and spore-patches nearly all died. "I [Mr. G. Ross] am of opinion that the disease has been checked on the treated area, and this opinion is strengthened by comparing it with untreated coffee elsewhere on the estate.

Results examined and testified by

15th January 1881, G. ROSS,

II.

II.—"I have carefully watched the *four acres* of coffee on this estate which were treated by both inoculation and vaporization according to Mr. Schrottky's system, and under his direction. In addition to what I reported at the time the results were examined, I now state that as far as I can see no injury whatever has been done to the coffee on this area. Nor is leaf-disease present to any appreciable extent. The attack, however, is apparently passing away all over the estate.

"The *one acre* referred to by Mr. Mackenzie situated some distance from the field referred above, received an overdose. This was done at Mr. Schrottky's request with a view of gaining experience of how far the chemical could be used with safety to the trees. A very heavy dose (applied through Week's patent sulphurator) and two doses of usual strength (a handful to a tree) applied all within ten days were followed by a fall of leaf greater in the so-treated area than in the surrounding untreated coffee. I think the damage is confined to this, as the trees are now making new wood.

"On the margin of this patch, there were at the time of treatment, some trees very heavily laden with rust, and Mr. Schrottky remarked that he did not expect much impression could be made on these. It was from one of them that Mr. Mackenzie carried away the branch which he sent to Colombo."

7th February 1881. G. Ross.

III.

The management of this estate changed and the next manager writes:—"In reply to your request to report on the coffee, on which you experimented, I can only state, that it is certainly looking very well and does not appear to have suffered at all from the application of your treatment. There is apparently very little leaf-disease on any portion of this estate.'

6th June 1881. T. C. HUXLEY.

Results of my own inspection is very much to the same effect. There is however, palpable evidence that of what little disease there is generally, there is appreciably less on the treated than on the untreated area. The one acre field looks well, but the four acre field looks, I think, remarkably well.—E. C. S.

OPERATIONS ON A LARGE SCALE.

A few observations made of the immediate result of the application will perhaps be acceptable. But here we are looking now for a broad, general benefit, which I think, there can be no further doubt, will ultimately result, if my instructions are carried out and the treatment persevered in.

I.

Gangapitiya Estate, 150 *Acres*.

About ten days after application: "I examined some of the leave that had a bad attack on them (before treatment) and it appeared, as if the lime and carbolic was killing or eating up the fungus, and left the diseased patch with the same appearance, as if the leaf-disease insect had been feeding and sucking out the spores. But some seem still to have escaped." Extract from estate reports to Messrs. Whittall & Co. by

30th April 1881. L. B. VON DONOP.

II.

"I met Mr. Schrottky this morning at Gungapitiya, and we examined together the result of the treatment here. He considers them most satisfactory, and *so far* as the experiment has gone, I most certainly agree with him.

"In exposed places such as along roads and ridges trees were found very badly effected, but this it appears is caused by the powder [or rather its vapour,—E. C. S.] being blown away from there, as inside for every twelve leaves affected, only on one could a living fungus be found. The rest of the leaves had a black spot, where the fungus had been established. On those where the disease had only commenced, a dried-up pale yellow mark was observable but in both cases (which I consider most important), the leaves appeared healthy and performing their functions." Extract from a letter to Messrs. Whittall & Co., by

L. B. VON DONOP.

31st May 1881.

From my observations I came to the conclusion that this estate has passed through a pretty severe (as evidenced by the large number of dead pin-spots throughout the estate) attack of leaf-disease during this month, but which had failed to develope itself, except in places where the treatment could reasonably be said to be able to exert little or no influence. Two applications were given. E. C. S.

Pallekelly Estate, 100 *Acres*.

"Undernoted is what I have to say on the 100 acres treated with the carbolic lime. The field had its first application on 18th April (2nd on 19th May.) Then leaf-disease was not very noticeable, only on a few patches was it bad.

"Looking at it to-day, these patches have decidedly improved and comparing the field with untreated coffee, the comparison is most satisfactory as regards the effects of the treatment.

"The leaf-disease found on the treated portion was only a few isolated spores on a tree here and there, whereas on the untreated portion the diseased leaves are covered with spore patches (16 leaves with isolated spores were picked from the treated area in six minutes, whereas in the same time 76 leaves—badly diseased—were got from the untreated coffee.)

"*P. S.*—The calculation worked out is about one and one-third spore-patches on the treated, to 40 spore-patches on the untreated."

31st May 1881. H. J. VOLLAR.

I am, Sirs, your most obedient servant,

EUGENE C. SCHROTTKY,

Technical and Agricultural Chemist,
Author of
"The Principles of Rational Agriculture,"
"Bombay Waters and the Albuminoid of Ammonia Test,"
"Man, Plant, and Soil and their Co-relations,"
"The Chemistry of Indigo Manufacture,"
"The Red Spider,"
and late Editor of the *Indian Agriculturist*.
Colombo, 7th June 1881.

A PLANTER writes:—"W. got 18 months ago 'Liberian coffee' seed, and it all came to be ordinary coffee, or did not germinate at all, and for the latter he was supplied with about 60,000 more about a year ago. In consequence of it all coming like this, he has lost a clearing for a year, and——who bought plants has also lost about 30 acres. And this seed got from those supposed to be noted planters and a fine men. I suspected for a long time, but for months I was

not looking after the place, and I have only now resumed management, and in doing so I told all I thought, and wrote to all the people who had bought plants, and my answer is the same: 'Plants no use, undoubtedly common coffee.'" This is certainly a very hard case; but if the seed was imported, it may turn out not to be ordinary *Coffea Arabica*, even though no larger. One Ceylon planter who visited Liberia told us he saw coffee from the size of a pea (St. Thomé coffee) up to the largest Liberian. Our correspondent's may turn out after all to be a new West African variety. Wait a little longer.

COFFEE IN COORG.

OUR correspondent writes from Mercara under date 1st August: "There is a very fair prospect of securing a good average crop of coffee this season, as far as my estimate goes, there is upon the trees or rather in the country now from ten to twelve thousand tons. This, is as you are aware, with having no statistics to base the fact upon a good deal of guess work, but reckoning the estimate formed in July 1880, at five thousand tons, it is as nearly exact as possible. The coffee crop in Coorg for 1880 was undoubtedly a failure all over the country. The blossoming was good, the season was good, but from some unknown cause, the berries never matured—they dropped off the trees in July and August. In no instance did a planter's crop come up to this first estimate. In many cases it was a third, and in some only a fourth of what was promised by the blossom, owing to the berries ripening very quickly on being prepared and dried and sent down to the coast for cleaning, &c., an excellent out-turn was obtained; 84½ bushels of parchment coffee making the ton which is reckoned to be as good as it well can be in 1879 the outturn was 91½. The beans were only moderately large, but were of good color—of a uniform light blue; and the prices, realised in the London market ranged from 74s. to 124s. per cwt. The early showers from bringing out the coffee blossom fell this year first on some estates fifteen miles from Mercara down the Mangalore ghât on the 19th of March, from thence the showers took a more northerly direction, and finally on the 2nd of April the rain had been pretty well scattered over all the country. The showers in March were more intensely local than can be recollected for many years; estates bordering upon each other with only a belt of jungle dividing them; the one might have two inches of rain, whilst the other only a light sprinkling. The following day this would be reversed for strange as it may seem there is a peculiar dispensation providing that thunderstorms seldom discharge themselves on the same ground that has been previously rained upon. It has unfortunately happened this year that more than one estate was deprived of rain until the beginning of May, which was too late to do good, the consequence being a total failure—and this coming upon last year's bad success, was doubly hard to bear. I think there can be nothing more disappointing or tantalising for a man than to be helplessly waiting for that shower which never comes, whilst day after day the surrounding estates are well watered, and he alone is isolated. Up to the end of July the season for coffee has been especially favorable, light showers and sunshine in June and July have given the trees exceptional vigor and growth, and the berries can be compared in size to those of last year on the 15th of September. Leaf-rot has shewn up in patches, but otherwise everything is well forward and the young supplies very vigorous. In South Coorg, with a lower altitude, a hotter climate, and a third of the rain-fall July was an unfavorable month, the country became parched and much crop was lost for want of succulence so that the estimates of June, I regret to hear, have been reduced considerably: the supplies have died and some new clearing wholly wasted, whilst the borer has made considerable havoc upon many promising places. There is no scarcity of labour, for owing to the want of rain in the low country, the coolies (or as many as are wanted) came in early to be employed upon the coffee estates. The remainder will come in at the close of this month, so that on the whole, this year's coffee prospects are not unfavourable.—*Madras Standard*.

COFFEE PLANTING IN JAVA.

EXTRACT from a Java letter to a correspondent in Ceylon, kindly placed at our service:—Leaf-disease does not do any harm at—estate this year. I have not seen one leaf diseased, but at other estates I hear they are not totally exempt from it, but it has no great influence on the crop. I have 4,000 piculs this year from 970,000 trees bearing fruit. The whole plantation when in full bearing, will be 2,070,000 trees." Our correspondent writes:—"The cost laid down in Samarang of the 4,000 piculs will be about Rs. 11 per picul." The picul is 133⅓ lbs., so that, nominally, this means coffee delivered at the shipping port for about 18s. per cwts! This certainly beats anything ever done in Ceylon, but we must remember the system of serfage which prevails in Java. It is a most convenient system from the point of view of the planter, and the native is also well off materially; but of course, one would rather be the free planter than the bondsman labourer, and indeed, would rather be the free, if lazy and sometimes hungry Sinhalese, than the apprenticed well-fed even if well-worked Javanese. The yield of crop reported above is nothing wonderful, say that the 970,000 trees are equal to 1,000 acres in Ceylon, it would amount to about 4½ cwts per acre.

LIBERIAN COFFEE.

THE species of coffee which is indigenous to Liberia, in West Africa, seems destined to have an important influence on the industry of those countries in which the coffee-blight has almost extinguished the Arabian coffee plant. A little pamphlet by Dr. H. A. A. Nicholls, just published by Messrs. Silver & Co., gives some interesting information on the cultivation of Liberian coffee in the West Indies, and especially in Dominica. The plant was first grown in England in the Royal Gardens at Kew during the year 1872, and from thence seedlings were forwarded in 1874 to Dominica and to several of the colonies in the West Indies. Fifty years ago Dominica was essentially a coffee country, at one time, indeed, over three million pounds of this staple were exported annually, and the coffee was of so fine a quality that the Dominica produce usually obtained the highest price in the English market. Unfortunately, however, early in the present century a blight attacked the trees, and within a few years it committed such ravage that the cultivation of coffee became almost extinct. Naturally, on the introduction into Dominica of a new species of coffee, more vigorous than that of Arabia, hopes were entertained that the leaves would be impervious to the ravages of the blight and these hopes, happily, were fully realised, for the young plants soon shot up into vigirous large shrubs, free from blight, and loaded with flowers and ripe and unripe berries. This immunity from blight enjoyed by Liberian coffee is, as Dr. Nicholls says, of the utmost importance to the welfare of Dominica and the neighbouring colonies, both English and French, for there is now nothing to prevent the islands of the Lesser Antilles from being once more large coffee supplying countries. In Dominica the cultivation of coffee may be said to be re-established, although it is only yet in its infancy, and the productiveness of the Liberian trees is a matter of astonishment to those of the older residents, who remember the coffee estates of 40 years ago. The Liberian coffee plant is much larger than that of Arabia, being, indeed, in its native state, a small tree. It has several other characteristics which render its cultivation different from that of its Arabian congener, and gives it several advantages all in favour of the planter. Its leaves are much larger; it flowers for several months, so that flowers and berries may be found on the same plant, and the berries are twice the size of the ordinary coffee bean. The ripe berries do not fall from the tree, like the ordinary coffee plant, but remain on the tree, without detriment to their quality for weeks; an important feature where it may be difficult to procure the labour necessary for speedy gathering. Dr. Nicholls gives many useful details as to the mode of cultivation and preparation. The flavour of the coffee, he maintains, is excellent, and he adduces evidence to show that it is quite as good as Java coffee. The success of the Liberian coffee in Dominica has been so great that already large supplies of berries are exported to several neighbouring islands. The history of the establishment of the new cultivation, Dr. Nicholls tell us, is full of promise to the future of the island. The plant is thoroughly acclimatized, the young trees are unaffected by blight, and their fruitfulness surpasses all expectations. In the island there are many abandoned estates, and large tracts of virgin soil, well watered with fine streams, eminently adapted for the cultivation of coffee and limes and other tropical plants. The plant has also been introduced into Ceylon, and Liberian coffee from that island has lately obtained 93s. per cwt in the New York market—that is, 12s. above the quotation at the time for middling plantation Ceylon (Arabian) coffee to the London markets.—*Times*, July 2, 1881.

COFFEE AND ITS ADULTERATIONS.

THE following extract from a London paper shows that attention is being given to this matter in England:—

"A very important subject for all tropical producers is the condition in which their produce finally reaches the consumer. Efforts, legislative and otherwise, are constantly being made to prevent adulteration, or if the public taste demand that other things should be mixed with the main article, those other things ought to be clearly known and defined to the purchaser, and it should indeed be at his option whether the mixture should be made at all. The mixture for instance chicory with coffee, if it is clearly understood, does no harm. A good many of the British public under a mistaken impression and with its false taste, prefer chicory with the coffee, but this is no reason why anybody, preferring the pure coffee, should be compelled to swallow a mixture they do not like. Substitutes for coffee, but claiming its name, are springing up. The so-called date coffee surely has no right to be called coffee, which is well recognised as the particular produce of a particular tree, and the French coffee which is sold in tins so largely at 10*d*. per lb., although pleasant to the taste, can hardly be Ceylon plantation. These general remarks have been suggested by reading an article in the *Ceylon Times*, embodying a proposed petition to the Secretary of State, regarding the legalized adulteration of coffee. The petition says that a capital of ten millions sterling has been invested in coffee production, and it is the staple on which Ceylon depends. It shows how the revenue of the island has increased as the coffee exports have grown. It declares that the public taste in Great Britain is vitiated by the almost universal practice of adulterating coffee. In countries where the unadulterated coffee is sold alone, the consumption has increased. In Great Britain it has fallen off, the consumption being 14,540 tons in 1880, against 16,780 tons in 1849. There is no doubt the Ceylon planters have a real grievance to place before Lord Kimberley, but whether his lordship can help them is another thing. If a purchaser goes into a shop and asks for coffee unmixed, the seller is bound to supply him with the exact thing he wants, under pains and penalty, and a system of public analysis has been established to act as a check upon the honesty of the seller. What is really wanted, that would satisfy the Ceylon planters, is an improvement in the public taste. There can be little doubt that genuine coffee will always hold its own, for no substitute or combination could ever permanently usurp its place, or really emulate its qualities. The consumption of coffee in the United Kingdom in 1880 was, as stated above, 14,540, and that of chicory 5829 tons, which, it must be confessed is a very large proportion, and justifies the complaint which is coming home from Ceylon, that true coffee is not appreciated as it should be.

Again, with regard to sugar, so many substances have saccharine qualities, that the name does not now represent any particular source from which the finished article is derived. Formerly the word sugar always suggested the cane of tropical countries. In later years, the beetroot claimed equally prominent attention, and now so many materials exist from which sugar can be taken that the mere word conveys no idea of its source. But it is clear that only that product can be called sugar which is crystallizable. The product called glucose cannot be sugar, and its distribution under that name, whenever it occurs, is undoubtedly wrong and misleading. There are a number of glucose factories in the United States consuming 21,000 bushels of corn per day, each bushel yielding on an average 25lbs. of glucose. The glucose syrup is mixed with cane syrup, and from the mixture a kind of product is made called the 'new

process sugar.' Now to sell this mixture as sugar, when there is only a proportion of true sugar in it, is, as the *Journal of Applied Science* says to palm off upon the public an article which professes to be what it is really not. The subject is one which eminently deserves the attention of the tropical sugar producers, whose interests may be severely injured by this so-called 'new process sugar.' It is a matter too to which the attention of the Board of Trade, which deals with questions of adulteration, might properly be called.

CACAO.

CACAO IN ECUADOR.

THE *American Mail* tells us that the Christmas crop of cacao in Ecuador (usually a fair indication as to the probable yield of the entire crop of the year) proved to be very small, and a cacao on the spot was quite scarce. There had been continual and heavy rains, to a considerable extent destroying the blossoms. Consequently only a small crop is expected in 1881. The total production of 1879 was 315,342 quintals, and that of 1880 has been ascertained to be 338,785 quintals. The quintal is 100lbs. but whether the lbs. are the same as the English lb. we do not learn. The French metrical system is the only legal one, but commerce still clings to the old weights—as it does with us for cacao to the arroba, of 110 lbs. English, instead of the cwt., or the very convenient cental of 100 lbs. Engl. introduced into Liverpool for certain articles, from New York. Ecuador had 85 miles of railway in 1877. Its public revenue in the year 1876-77 was £340,966.—*Trinidad Chronicle.*

TOBACCO CULTIVATION IN THE PHILIPPINES.

"A TELEGRAM dated the 26th June, has been received from the Minister for the Colonies to the following effect :—

"*Gazette* publishes to-day the following Royal Decree:"

1.—From the 1st July next year the sowing and cultivation of tobacco in the whole of the territory of the Government General of the Philippines will be entirely free; also its manufacture, sale, and interior consumption, from the 1st January of the successive year.

2.—Of the crops the appraisement of which will be begun in August of next year, the Administration will take charge on the usual terms. The Director-General of Government Estates will see that the Government manufactories produce only so much as may be necessary for the interior consumption until their place can be filled by private enterprise.

3.—In order to supply the want of manufactories in Spain, a tax will be charged on tobacco leaf, divisible among all the provinces where tobacco is grown, enough to cover the said want in the quantity fixed by Government estimates as subvention, and in accordance with existing conditions.

4.—In order to reimburse the deficit which will occur in the estimates through this reform, the Minister for the Colonies is authorized to establish taxes, not to exceed ten per cent. on one quintal (100 lbs. Spanish) of tobacco leaf and cigars intended for exportation; also to equalise the existing personal taxes, on the basis of a reduction of the time allowed for payment, which shall not exceed twenty days; also to reform the present tariff of duties.

5.—The Minister for the Colonies in accord with the authorities and Corporations of the Archipelago and Council of the Philippines, will submit for the examinations of the Council of State the regulations and necessary instructions for the execution of this decree.

6.—The Government will inform the courts of this decree.

This is published in the *Government Gazette* for general information,

(Signed) PRIMO DE RIVERA.

Manila, 6th July 1881.

Manila Gazette.

STATISTICS.

THE trade of Singapore during last year, exceeded the previous year by nearly ten million dollars. The total imports and exports during the last decade were as follows :—

	Imports.	Exports.
1870	$39,058,564	$31,731,022
1871	36,766,530	32,003,807
1872	43,415,383	39,020,121
1873	47,880,090	41,752,115
1874	46,887,070	41,508,798
1875	43,766,201	41,619,519
1876	45,466,070	40,614,783
1877	49,327,317	41,428,407
1878	47,259,337	39,421,921
1879	56,278,292	49,250,238
1880	60,675,733	54,578,981

AN American exchange tells us that since 1st January 1881 over 10,000 miles of railroad have been built in the United States, and over 720,000,000 dollars new capital raised for the purpose. This is at the rate of £9,000 per mile, and although the American system of railways is not so substantial as ours perhaps, still the purposes for which they are constructed are served. It may be noted that this length of line, built in a few months, is almost twice as much as we in India have built since the commencement of the railway enterprise in 1853.

THE population of the United Kingdom is an interesting study. The following table gives details of the recent Census, as compared with the last in 1871 :—

	1871.	1881.	Difference per cent.
England and Wales ...	22,712,266	25,968,286 +	14·33
Scotland ...	3,360,018	3,734,370 +	11·14
Ireland ...	5,411,416	5,159,839 −	4·65
Channel Island and shipping	373,638	384,067 +	2·79
Total	31,857,338	35,246,562 +	10·64

The population of London has increased from 3,254,260 in 1871, to 3,814,571 in 1881, or at the rate of 17·21 per cent., and is now more than the whole of Scotland.

EDUCATIONAL statistics in Europe are interesting, and furnish material for comparison with what is doing in India. The following figures are from a return now being issued by the United States Bureau of Education. "The following are the educational statistics of countries which have more than a million pupils enrolled :—

Countries.	Date.	School Population.	Pupils Enrolled.
Austria ...	1878	3,122,863	2,134,683
England & Wales ...	1879	2,500,000	3,710,883
France ...	1877	6,409,087	4,716,935
Hungary ...	1877	2,127,950	1,559,636
Italy ...	1876	4,527,582	1,931,617
Japan ...	1877	5,251,807	2,162,962
Prussia ...	1871	4,396,738	4,007,776
Russia ...	1876	15,000,000	1,213,325
Spain ...	1870	2,603,265	1,410,475
United States ...	1878	14,596,183	9,373,195

The value of these statistics, however, depends almost entirely upon the "school age" adopted in the different States. In America it averages fourteen years, in Europe seven. With a school population of 2,500,000 Great Britain is reported to have no fewer than 3,710,883 enrolled on school registers. The pre-eminent distinction of having 50 per cent. more children at school than the total number of our school population is however more apparent than real. The "school population," is limited to children between seven and thirteen, the "pupils enrolled, included those from three to fifteen. When the figures are adjusted so as to take only those of the same age under both heads, the number of pupils enrolled is reduced to 2,333,973.

THE following table illustrates the relative increase in the various departments of trade during the past ten years in the United Kingdom and in the United States. There can be no doubt that it exhibits an increase on the part of the latter nation at such a rate as shall speedily place America at the head of the list of the trading nations. The table is taken from Mulhalls' *Balance Sheet of the world* :—

	Millions Sterling.
British commerce increased during the decade	145
United States commerce increased in same period	120
British manufactures increased	116
United States "	206
British Mining "	19
United States "	34
British agriculture decreased	20
United States increased	110
British carrying trade increased	43
United States "	26
British sundries "	6
United States "	8
British banking "	28
United States "	35

THE following statement is from the *Economist* and shews the indebtedness of the United States at the three periods 1865, 1880, and 1881—

Rate of Interest	July 1, 1881. $	July 1, 1880. $	August 31, 1865. $
7·3 per cent.	...	...	830,000,000
6 per cent.	...	235,780,400	1,281,736,439
5 per cent. ...	76,000,000	484,864,900	269,175,728
4½ per cent. ...	250,000,000	250,000,000	...
4 per cent. ...	738,652,950	739,347,800	618,128
3 per cent. ...	14,000,000	14,000,000	...
3½ per cent. ...	544,219,950	...	...
Bonded debt	1,622,872,900	1,728,098,100	2,381,530,295
Yearly interest. ...	64,063,816	79,633,981	150,977,698
Average rate of Interest...	3·94	4·62	6·34

It will thus be seen that in 16 years the American Government reduced their debt from 476 millions sterling, to 324, and the annual charge from 30 millions sterling to 13. This is

what can be done by a little energy. The security offered by America is certainly no better than that offered by India, and yet our annual charge for interest is close on five per cent. To enable us to save a large sum annually we must refund, and the result of the last Loan shows that we can do that at 3½ per cent., possibly at 3 per cent. For this operation we want statesmanship and energy, and Major Baring has thus a great opportunity.

THE strides which the United States are making, constitute an interesting study. The republic of America is but of yesterday, and yet she stands well up in the list in the order of national wealth. The latest statistics on the subject of capital valuation are as follows :—

United Kingdom	£8,880,000,000
France	£7,340,000,000
United States	£6,400,000,000
Germany	£4,400,000,000
Russia	£3,000,000,000
The Netherlands	£2,230,000,000

The annual income per head of population brings the United States even more to the front. The statistics on this head are as follows :—

	£
United Kingdom	33
United States	35
Netherlands	26
France	25
Germany	17
Scandinavia	17

The former table is perhaps a fairer test of national wealth, because the question of income is so mixed up with the cost of living, that a bare statement of income is not a correct test. One man may have a better income than another, but relatively to the cost of living, his income may be much less.

As a contrast to the progress making by America in reducing her national debt, the progress in the other direction being made by Russia is remarkable. In 1878 the national debt of Russia stood at £350,000,000, and at the close of 1879 it had increased to £490,085,900. This large sum is only £5-10-0 per head of the population, but when the poverty of the Russian peasant is taken into account, this seems a very large sum. The debt of the United Kingdom is equal to £22 per head, and although this is four times as heavy as the incidence of the Russian debt, it is relatively much less, owing to the comparative prosperity of the English peasant.

CONFERENCES seem fashionable at present, and we observe that the European brewers have been, indulging in one. Statistics presented at the meeting show that England does not deserve the name she has acquired, of being a beer-swilling nation. The quantities consumed are as follows in quarts per head of population :—

Bavaria	269
Belgium	149
England	143
Austria	31
France	21
Russia	2

It must not be supposed from this that Russia is a particularly sober nation, the fact being that the Russian drinks something much stronger than beer. The quantities of spirits consumed in the United Kingdom were as follows, also in quarts per head of the population :—

England	3·86
Scotland	10·20
Ireland	6·09
Average	4·85

This is a tolerably heavy bill, and it is one of the most absorbing problems which occupy the attention of social and political economists, to find out where the money for all this liquor comes from.

SERICULTURE.

SILK GROWING IN AMERICA.

THE rapid growth of the silk manufacturing interest in the United States was recently made evident in these columns by a review of the census statistics gathered by Mr. Wycoff. Commenting upon the same facts, and the superior quality of American manufactured silk, the Philadelphia *Public Ledger* gives a large amount of interesting information touching the production of raw silk and its possibilities in the United States.

"It is as easy to raise cocoons as sheep—easier. The intermediate stages between the cocoon and the factory have yet to be undertaken, but cocoons and eggs are both raised in this State, in North Carolina, and in Missouri, for sale and export. The shearing of the cocoons, or the filature is the step that has to be taken on an extended scale. The great cocoon market for the world is Marseilles. The silk filatures are grouped in the departments around Lyons, and the French raised cocoons are consumed in the immediate neighbourhood in which they are raised; but the foreign cocoons, coming from all countries, are distributed from Marseilles, and there they are purchased to the best advantage. Consuls Peixotto points out in a private letter to the American Minister at Paris, in answer to some inquiries made through Mr. Noyes by the Philadelphia silk school, that American-grown cocoons can be sold at Marseilles as readily as any others, as soon as the quality, and especially the uniformity of the cocoons become known in the markets. By the efforts of this school American-grown cocoons will doubtless soon be placed on sale in this important depôt to direct the attention of American silk raisers to this point. There have been already given in the *Ledger* such details of silk growing under the management of this school as will satisfy any one that all that is needed is such a point to which the numerous little harvests all over the country can be gathered and forwarded. Here is one experience from Gwynedd, Pa., representing six weeks' care of one crop. There were raised in one farmhouse, just as an experiment and to see how it would work, thirty pounds of cocoons and fifteen ounces of eggs. The cocoons are worth at a market two dollars a pound; the eggs, from three to four dollars an ounce. From a North Carolina farmer comes a letter on a larger scale. He has put up one hundred and fifty racks this year, four feet long by three wide, and each rack is to accommodate two thousand worms. He expects to raise this summer one thousand barrels of cocoons (North Carolina cocoons, pure white, took a permium at the Centennial); but this grower raises also from the French eggs the large flesh-coloured cocoons, of which about one hundred and ninety weigh a pound, and from the Japanese eggs also a fine cocoon.

"But why, asks the protective and otherwise thoughtful reader, need the cocoons be sent abroad to be sold, and this golden fleese sheared by French hands? Why can they not be kept at home, seeing that the silk manufacturer can, or at least could, take all that can be raised for years, to come? That is the point which is now occupying the minds of *sericulturists*—seriously occupying them. Cocoons and eggs and all that, they know. They know that the mulberrry will grow wherever the apple tree does, and that the osage orange does about as well as the mulberry. They know that the season begins on the 11th of May and lasts six weeks, and that it is possible, by skilfully retarding some of the eggs to make two seasons in the year. What they have not yet reached is the perfection of reeling, although they are experimenting upon it. The hand reeling of Italy and France is an old story. Silk has been reeled by hand here, and is still, and if the farmer's daughter puts her reeling at the same price as her knitting or crochet, to fill up the unemployed time, and not for an occupation to live by, hand-reeling would pay to that extent. For an extended business the great filatures are needed, where American cocoons can be reeled at home by machinery, the only thing that can come into competition with the cheap day labour of the Italians, French, and Japanese hand reelers. A young American engineer is at this time in France, experimenting on the reeling of silk by electricity, which is the motive power destined to lighten labour as well as streets. This is the one missing link that is needed to complete the chain between Horstmann's fringes and ribons and the New Jersey silk dress goods and handkerchiefs, the Connecticut sewing silks, &c., and the cocoon racks in American farm-houses. The Philadelphia school, that has done so much in gathering up these threads of detail, and in sending out its cocoons and instruction over the country, is a real credit to the city and the State."

TOBACCO.

SHOULD the report that the Spanish Government is about to discontinue the tobacco monopoly in the Philippine Islands prove true, one of the closest and most strictly enforced monopolies that ever existed will be put an end to. The production of the Manilla cheroot was fenced about with protective regulations even from before the moment that the tobacco seed was put into the ground almost until that at which it was placed between the lips of the smoker. Some land in the Island of Lucon being better suited to the cultivation of the plant than others, all owners and occupiers of property in certain districts had to see that a proportion of their land under cultivation—the amount being regulated by the Government—was devoted to growing tobacco. The kind of seed sown and the mode of rearing the plants were closely supervised by the authorities. The product of the harvest could be purchased only by the Government; and no one else could manufacture it into cigars or cheroots. No unmanufactured tobacco could be sold even for exportation, unless it were to be carried beyond the Cape of Good Hope—a regulation made to prevent the starting of a rival manufacture at Macao or Hong-Kong. The factories of Manilla and Cavite are immense establishments. Every visitor to the former city must have been struck by the crowds of "hands"—chiefly Tagal women and girls—which stream out of their gates at the close of the working hours. Their interest in the proposed change must be considerable.

THE system pursued in Cuba has long been altogether different. The *vegas* or tobacco farms of the celebrated Vuelta Abajo—the region in which the finest tobaccos are grown—are usually small holdings cultivated chiefly, if not entirely, by white men. Slave labour in Cuba has had little to do with the production of at least the raw material of the celebrated Havana cigars, but was principally employed on the great sugar estates. The cultivation of the plant, free as it is, is not more so than the manufacture of the cigars and cigarettes. Though the huge factories of Manilla are not to be found at Havana, a remarkable change in the system of cigar-making has taken place within the last five-and-twenty years. At the beginning of that period the small factories were many in number; some streets—notably the Calle del Sol and the Calle Obispo—were lined with little shops, in which might be seen some half-a-dozen white creoles vigorously smoking and rolling cigars. Some years later these had nearly all disappeared, and the manufacture had apparently passed into the hands of large firms with manufacturing establishments of considerable size. The great cigarette works of La Honradez were one of the sights of the city. Though perhaps not even those whose Eastern experiences tend to

preserve pleasant recollections of the Manilla plant will dispute the superiority of an Havana, it is worth remembering that the former was, and indeed is, by a long way the cheaper.

TOBACCO CROPS OF 1880 AND 1870.

J. R. DODGE, special agent for the collection of statistics of agriculture, has issued from the Census Office, a report showing the tobacco crops of the United States for the census years 1880 and 1870. The comparative statement in the report shows an apparent increase in the production of 80 per cent. during the decade, the product in 1880 being placed at 473,107,573 pounds, and that of 1870 at 262,735,341 pounds. This apparent increase, Mr. Dodge says, exaggerates the real advance in tobacco cultivation, at the preceding census the crop was a small one, and the fear of taxation may have operated to prevent a full crop of tobacco in 1870. The crop reported in 1880 was one of medium production, not in excess of present requirements for home demand and export. Fifteen States produce now, as in 1870, more than 99 per cent. of the tobacco of the United States, although it is reported in twenty-two other States and six territories. Of these fifteen, only Missouri, Illinois, Indiana, and Massachusetts produced less than in 1870. Kentucky occupies the first position, producing 36 per cent. of the total product of the country. Virginia then holds second place; Pennsylvania has advanced from the twelfth to the third; Wisconsin from the fifteenth to the tenth; and North Carolina, Connecticut, and New York have each gained one point in the rank of tobacco States. Those that have retrograded in relative production are Massachusetts, Maryland, West Virginia, Indiana, Illinois, Missouri and Tennessee. The average yield per acre is shown to be 731 pounds, varying from 1,599 pounds in Massachusetts to 471 pounds in North Carolina. This variation in the rate of yield, the report states, is due in differing degrees to the use or neglect of fertilizers, the habit of growth of different varieties and vicissitudes of season.

The following table shows the total product in pounds and yield per acre in 1880 in fifteen leading tobacco-growing States.

States.	Total Yield.	Average.
Kentucky	... 171,121 134	756
Virginia	... 80,099,830	553
Pennsylvania	... 36 957,772	1,340
Ohio	... 34 725,405	1,001
Tennessee	... 29 065,652	707
North Carolina	... 99 286 418	471
Maryland	... 26 082,147	683
Connecticut	... 14,044,652	1 620
Missouri	... 11 991,077	773
Wisconsin	... 10 878 463	1,234
Indiana	... 8 872 842	742
New York	... 6,553,351	1,327
Massachusetts	... 5 369 436	1 599
Illinois	... 3 396 700	699
West Virginia	... 2,296,140	[illegible]

TOBACCO TRADE IN CEYLON.

THE trade in this article seems to suffer from greater depression produced by causes which are not far to seek. Tobacco exported to India last year remains in stock, there being no demand. The Indians turn out as good tobacco as any sent from Jaffna The crop produced in India this year is reported to be sufficient to meet the demand there. Another cause is that a larger number of men than in any preceding year having taken to tobacco cultivation, the outturn is far in excess of the demand. This year's crop has been gathered in, and the market is now flooded with tobacco. Prices have considerably fallen. We are assured by men whose veracity is unimpeachable that it is found difficult to sell tobacco even at a rate that would barely cover the expenses of cultivation, the cultivator making up his mind not to charge for his labor and trouble. This is indeed a sad state of things. None but those who are acquainted with Jaffna affairs are able to understand what depression in tobacco means. As we have often remarked the chief industry of the place is the cultivation of tobacco: when tobacco produced at great trouble and expense lies in hands uncalled for and unsold, you may safely conclude that distress and want have made their appearance. Money is very scarce: tobacco cultivators struggle hard to keep body and soul together, and we fear that should this depression continue even for a short time it will affect the well-to-do classes.

The only class of men that seem to derive benefit from the existing depression are the cigar traders. They combine and keep down prices. The mysteries of trade are so strange that what is ruin to one is a benefit to another. Now that there is no demand in India for tobacco, the cigar traders buy it cheap, and rejoice in the prospect before them.

Times of depression are also times of sickness. When tobacco is dull or when paddy is short, you may expect with certainty the appearance of some sickness, which generally drives people to live upon unwholesome articles. It was so in 1877. A speedy change in the trade is very desirable, and any measure calculated to effect it, will be heartily welcomed.—*Jaffna Patriot.*

MADRAS GOVERNMENT SCHOOL OF AGRICULTURE.

A NEW class will be formed in September. For rules of admission, &c., see Fort St. George Gazette, dated the 16th of August 1881, Part I, page 434, or, apply to the undersigned,

(8d.) W. R. ROBERTSON, M.R.A.C.,
Superintendent Government Farms.

GOVERNMENT FARMS OFFICE,
Saidapet, 24th August 1881.

We publish the following papers at this Office :—

THE INDIAN AGRICULTURIST.
(MONTHLY.)
Rates of Subscription, including postage.
STRICTLY IN ADVANCE.

For India	Yearly	Rs. 12 0
	Half-yearly	„ 7 0
For Europe	Yearly	„ 13 8
	Half-yearly	„ 7 8

Single copies, Rs. 1, back copies, Rs. 2.

Advertisements for the "Indian Agriculturist" should be sent in not later than the 23rd, to appear on the 1st of the following month.

THE FRIEND OF INDIA & STATESMAN.
(WEEKLY.)
Rates of Subscription, including postage.
STRICTLY IN ADVANCE.

		Town.	Mofussil.
For India	Yearly	Rs. 20 0	Rs. 22 0
	Half-yearly	„ 11 0	„ 12 0
	Quarterly	„ 6 0	„ 7 0

The reduced rate for Missionaries is Rs. 15 per annum.

For Europe	Yearly	Rs. 26 8
	Half-yearly	„ 14 0

Single copies, As. 8, back copies, Re. 1.

Advertisements for the "Friend of India" should be sent in not later than Wednesday, to appear on the following Saturday.

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

FORESTS AND MALARIA IN BURDWAN.

TO THE EDITOR.

SIR,—In 1879 our attention was directed by a certain vernacular newspaper, the *Somalochuk*, to the febrifugal properties of the willow tree, by the plantation of which Cyprus had been deprived of fever, as stated by the correspondents of the *London Times*. Baboo Trailakhya Nath Mukerji, the Darjeeling correspondent of the *Somalochuk*, proposed to us to inform his Highness, the Maharajah of Burdwan, of the virtues of the willow tree, to prevent fever, and to request him to plant the same along the sides of every road in Burdwan. We, being totally unacquainted with the virtues alluded to, had occasion to search through the leading botanical authorities of Northern India, and while so engaged, we received much information regarding the virtues of many trees, to lessen the cause of malarious fever.

With regard to the virtues attributed to the willow tree, to prevent fever, Dr. King, Superintendent, Royal Botanical Garden, Calcutta, thus states in his letter of the 20th April 1879 :—"Salicin, an alkaloid obtained from willow barks has some power as a febrifuge, but is much inferior to the cinchona alkaloid. I never heard that willow trees have any influence in preventing malaria in feverish districts."

In August 1880, we asked the Superintendent, Royal Botanical Garden, Calcutta, for information regarding the virtues of the sunflower, *toolsee*, tobacco, maize, and willow. In his letter No. 1138, dated 7th August 1880, Dr. Cunningham, the Officiating Superintendent, said :—"There is no satisfactory evidence, as far as I know, that any of the plants, to which you allude have any *special* protective influence against the development of the cause of malarious fever."

With reference to the virtues of the abovementioned plants, Mr. Gollan, Officiating Superintendent, Government Botanical Gardens, N.-W. Provinces, remarked as follows in his letter No. 2316, dated 4th September 1880 :—"Plantations of the willow tree, sunflower, &c., or in fact anything will undoubtedly lessen the cause of malarious fever. Cultivation no matter of what kind will."

In his letter No. 3798, dated 17th November 1880, Dr. King reported :—"I know of no plant that has any specific influence in making feverish places less so. The relation of vegetation to malarious fever is a subject which I am not prepared

to discuss at length. If fever is caused by excessive moisture in the soil, the kinds of trees which most freely absorb such moisture, are of course most likely to diminish the fever. I am not aware that the *Pithecolobium saman* has ever been credited with any special virtues as a fever destroyer."

Mr. Duthie, Superintendent, Government Botanical Gardens, N.-W. Provinces, thus remarked in his letter No. 1112, dated 19th May 1881 :—" Regarding trees and the prevention of fever, I may say that Dr. King's remarks are so exactly in accordance with my own opinion on the subject, that I need not repeat the same. Any quick growing tree, such as, *eucalyptus*, *pithecolobium saman*, giris, willow, &c., planted on ground, become malarious from excess of moisture, will by draining the soil gradually lessen its feverish growing character.

Referring to the virtues of the *eucalyptus* by the plantation of which France, Algeria, &c., have been deprived of fever, as stated by the *Indian Agriculturist* for June 1881, Dr. King stated in his letter of the 14th June 1881, as follows :—" *Eucalyptus* will not grow in Burdwan as think I have already told you. If you wish to remove malaria by planting trees to drain the soil all over the district, you will undertake a very big job. I am sorry I cannot give you any further advice than I have already given."

With regard to the fever dispelling properties of the *neem* tree, as have been given in the proceedings of the Agricultural and Horticultural Society of India for June 1881, Dr. King said in his letter No. 40P, dated 9th August 1881, as follows :—" With reference to your letter No. 46, dated 7th instant, inquiring whether *neem* (*Melia Aya darichta*) and *toolsee Ocimum sanctum*) have febrifugal properties or any special virtue to prevent the cause of malarious fever, I beg to inform you that in my opinion they have none of the properties alluded to in your letter under acknowledgment.

" I can give you no further information about *neem* than you appear to be already in possession of."

In connection with the above, Mr. Gollan, thus states in his letter No. 1915, dated 13th August 1881 :—" In reply to your letter dated 9th instant, I agree with what Dr. King has told you about the *eucalyptus*. The climate of Saharunpore during nine months of the year is very much drier than that of Bengal. I have never found it difficult to keep any species of *eucalyptus* alive during the hot and cold seasons, but I have always found it difficult to keep all varieties alive during the rainy season.

" You seem already to know all the reputed virtues of the *neem* tree. I do not know what other information you wish to have. If you wish a botanical description of the tree, I shall gladly send you one.

" I do not believe very much in the virtues of any particular tree to remove malaria. The climate of Saharanpore is said to have been very malarious about 20 years ago. No one ever attributes the improvement in the climate to the planting of *neem* or any other species of tree, but every one is prepared to admit that an extensive system of drainage, executed by the energetic Collector some years ago, has greatly improved the climate. If your district is badly drained, which I perceive it is from your description, the most practical way to remove malaria is to begin and drain it, then plant *neem* or any other species of trees which your fancy may suggest as a finishing stroke to your work."

That systematic drainage is the only means for removing malaria, every one will admit. It is very interesting to note that in the Government circular resolution, dated the 29th April 1879, his Honor the Lieutenant-Governor came to the conclusion of what the late Rajah Digumber Mitter said that " one, at least of the chief causes of unhealthiness in Bengal, and of the fevers which in late years have done so much misery, suffering, and mortality among the people of large tracts of country, is the excessive humidity of the soil by obstruction to drainage." His Honor was pleased to direct the District Road Committees and municipal bodies to improve local drainage and supply good drinking water in the above resolution. From time to time we represented to the Burdwan Municipality the conditions of the villages in Ward C, which are still suffering from the fatal fever, and more than half of the population of which villages died only of fever, and strongly insisted on their constructing metalled roads supplying good drinking water and carrying out drainage works. The Municipality promised to redress our grievances, but as yet did nothing. In the resolution of his Honor the Lieutenant-Governor, dated the 12th June 1880, the municipal bodies and District Road Committees were further ordered to improve local drainage and supply good drinking water and proper conservancy. We then sent the following petition to the Burdwan Municipality, in which the condition of our village and the negligence of the Burdwan Municipality are fully described :—

To the Chairman of the Burdwan Municipality, Municipal Commissioner's Office, Burdwan, dated Khojanarber, Burdwan, the 1st November 1880.

The humble petition of the Municipal rate-payers of Khojanarber in C Ward, Burdwan.

Respectfully Sheweth :—That your petitioners are regularly paying their rates to the Burdwan Municipality, but unfortunately they have received as yet no benefit from the Municipality, that the road around your petitioners' village is full of mud during the rainy season, and full of dust during the summer and winter seasons ; that the road is never macadamised by the Municipality ; that they are drinking and bathing in very unclean and stagnant water ; that your petitioners are suffering from the great prevalance of malarious fever attributable to the presence of a superabundance of water, and that not fresh but stagnant water lying on the ground, which is caused by the negligence of the Municipality ; because it is admitted that after the rainfall is over, the water lies all about the village in pools and ponds, stagnating and breeding malaria, which would not have been the case if proper drainage works were carried out by the Municipality ; that in February last they together with the other inhabitants of C Ward petitioned the Municipality, craving redress of the above mentioned grievances, and that it was ordered on their petition that the Commissioners of C Ward should report where those works should be carried out, but to the wonder of your petitioners no report has yet been submitted by the Commissioner ; that your petitioners had occasion to read the resolution of his Honor the Lieutenant-Governor of Bengal on the improvement of drainage of towns and villages in Bengal, dated Darjeeling, the 12th June 1880, where it is remarked :—

"2. The Lieutenant-Governor is, however, glad to find from the reports received by Government that within the limits of Municipalities and Unions much has been done, since the issue of the Government orders of August 1876, to improve local drainage and to introduce that improved conservancy to which the Sanitary Commissioner very rightly attaches such great importance. Very much, however, still remains to be done, and the Sanitary Commissioner and local authorities must continue to devote unremitting attention to the provision of effective surface drainage in towns and villages, to the introduction of a proper conservancy, and to the purification of the supplies of drinking water. As already promised, if in any case municipal funds are inadequate for the carrying out of really useful schemes likely to do good on a large scale, the Lieutenant-Governor will be ready to consider reasonable applications for assistance. In Dinagepore and Rungpore, schemes of drainage have already been started with the help of Government, which are expected very materially to benefit those stations."

" Your petitioners therefore humbly pray that the Municipality will be pleased to make special arrangements in the Budget for the year 1881-82 for macadamising the road around Khojanarber, digging a well at Khojanarber for the supply of good drinking water, and supplying proper conservancy. And your petitioners as in duty bound, shall ever pray."

The following resolution of the Burdwan Municipality on the above petition, dated the 15th December 1880, should not be out of place here :—

" The Vice-Chairman next laid on the table for consideration a petition from the residents of Ward C for a well, drainage works, and a metalled road to be made in that quarter.

" Resolved that as provision has been made for improvements as stated in Clause 3 of the foregoing resolution the petition be filed."

The clause referred to above, is as follows :—

" 3. That Rs. 400 be alloted under the head ' local improvement ' for the sinking of a large well in Ward C, where the want of good drinking water is very much felt, and Rs. 200 for drainage

works, and that the Commissioners of the Ward be asked to select an open site for the well in Bere."

In April last the Commissioners of the Ward selected "an open site for the well in Bere," but as yet no well has been dug, nor any drainage works have even been commenced. It is necessary to mention here that in 1880 the Municipality resolved to sanction Rs. 1,000 for the improvements suggested by the Commissioners of the Ward, but not a single rupee has been spent for the improvement of the Ward, and it is very wonderful to note that out of that Rs. 300 was expended for the construction of a road in another ward which has no connection with C Ward. Such is the condition of our village and such actions are taken by the Municipality for the construction of roads supplying good drinking water and carry out drainage works.

Such is the condition of every village in Ward C. Some of the villages, such as Mirsoba, Nootangram, Degree, Mohunbag, Dewanganj, Ashatta, Batcharhat, and Ballanhat, are pure rural villages, who enjoy no benefit of road or other municipal improvements. They had occasion to represent their own condition to the Commissioner of the Burdwan division. In his letter No. 81, dated 14th April 1881, the Divisional Commissioner ordered the Magistrate to inquire into and report on their petition. The Magistrate of Burdwan submitted the report in which it is stated that the majority of the population of the above villages are chiefly employed in agricultural pursuits, and that no benefit of road, &c., are enjoyed by them. The Divisional Commissioners as well as the Municipal Commissioners therefore resolved to exclude the above villages from the Burdwan Municipality from the next official year.

The above exposition will shew that no action has been taken by the Municipality relating to the subject of drainage or supplying drinking water in Ward C. We therefore pray that Government will be pleased to appoint a Committee to inquire into and report on the state of the Burdwan Municipality, and to inquire into the sanitary condition of Ward C, and the measures adopted by the Municipality for improving the drainage of C Ward, and to call upon the Municipal Commissioners to take due measures for the drainage of Ward C, and then to plant different kinds of trees as a finishing stroke to the work under Government Circular Resolution dated the 12th June 1880. B. K.

COFFEE BUG.

(To the Editor of the Madras Mail.)

SIR,—With reference to the inquiry made by a "Planter," as to what would stop the spread of "bugs" in young coffee, I suggest, that if the bugs have already made their appearance, the best remedy is, to sprinkle upon the young plants a decoction of wormwood." Yours, &c.

C. B.

CASUARINA CULTIVATION.

(To the Editor of the Madras Mail).

SIR,—Referring to an extract from *The Eurasian and Anglo-Indian Advocate* which appeared in your issue of 20th July, regarding the cost of planting casuarinas, the writer says :—"It is estimated that under very unfavorable circumstances as much as Rs. 100 per acre will be required for the first year." On referring to his estimate for planting six acres I find, after deducting an item, cost of watering and all sundries, which I will suppose is expenditure incurred after the first year, the cost of raising planting and tending for one year, on six acres, to be Rs. 156 or Rs. 151 per acre.

The writer of the extract also says :—"Land for casuarina cultivation may be had for Rs 10 per acre. I shall say Rs. 20 to be on the safe side." On going to his estimated abstract of receipts and expenditure, I find Rs. 1,400 as gross expenditure on 6 acres ; but on referring to detailed account, I cannot find any charge for cost of land. Again a profit of Rs. 7,600 on an outlay of Rs. 1,400 would, by my calculation, be 542·8 per cent. instead of 550 per cent. Will the writer of this, or the editor of the paper referred to, be so good as to explain, and if I am wrong put me

Travancore, 3rd Sept. RIGHT.

INDIAN TEA.

(To the Editor of the Times.)

SIR,—In your leader of the 27th instant, you refer to the production of Indian tea, and allude to the damage done to the crops by the red spider.

As brokers, we are often asked for information on the subject, and after careful inquiry have come to the conclusion that the injury to the crop from this cause has probably been very much overrated.

It may perhaps, be satisfactory to your readers to learn that the new season's importations from India are so far generally of excellent quality, and that the crop promises to be a good one, both in this respect and as regards the yield.

The Secretary of the Indian Tea Districts Association alluded in *The Times* of to-day to the development of the industry. The deliveries will soon amount to 50 million pounds per annum, and there can be little doubt, considering the growing and high estimation in which Indian teas are held by the buyers throughout the country, that a very much larger quantity, if the standard of quality be high, would rapidly find its way into consumption.

Apart from our export trade, the delivery of China tea is about 116,000,000lbs. annually. It is fully expected that India will supply us this year with one-third of our total requirements.

For many years past Indian teas were only used for the purpose of blending with China, but it is now known that some of the largest retailers are selling them pure, with advantage to their trade, their customers disliking the admixture. We are, Sir, yours faithfully,

WM. JAS. AND HY. THOMPSON.

38, Mincing-lane, July 29.

SHORT CROPS DUE TO POOR CULTIVATION.

(To the Editor of the Ceylon Observer.)

SIR,—I agree with your correspondents who hold that crops which are short this year are due, not so much to season or elevation, since there are so many instances where a line of coffee separates, on the one, 10 cwt per acre from nothing per acre, on the other.

It would surely be a very extraordinary thing if a line which was not a mountain ridge could so influence as to separate the season on its either side ! The fact is, that wherever coffee was cheaply worked ast year, there the crop is bad ; let this cheap coruse be repeated, and next year the crop will be worse.

In most instances, wherever coffee was highly cultivated, especially in manuring, there the crop is very good. Where manure failed, the wood was too late and unmatured. This wood is now ready, but unfortunately this is not the blossoming season.

No improvement, but the reverse, unless they change hands, can be hoped for from estates too involved to afford manure.

Very much prominence is given to the Kelebokka valley this year where some places which have always been highly kept up are doing lust tolerably well.

But the crops there cannot hold a candle to some in Dimbula, and, after two such very short seasons, would have, three years ago, caused more grumblings than congratulations.

Is there not an error in the statement "that the crops from average estates there amounted to as much during the last five as during the five previous years?"

There was, it is true, a very heavy crop from every estate in the dry season of 1876-77, the surplus of which, by spreading it over succeeding seasons, helped to uphold the average, but its influence for such a purpose was expended some time ago, and if the average for five years, ending with the coming crop, were placed beside that of the five previous years, it would compare most unfavorably. With a generous expenditure upon manure, Kelebokka will, however, hold its own beside most other districts in the country.

TRAMP.

July 13, 1881.

IRRIGATION.

(To the Editor of the Indian Chronicle.)

SIR,—In the last issue of your paper, I have said that the scene on both the sides of the canal, which runs parallel to the Punpun is quite ruinous. There remains only one question to be answered, the question why the tenants inhabiting the left side of the canal do not manage to irrigate their rice crops with canal water. I have many things to say why they do not. If I can point out to your entire satisfaction the inconveniences of buying water from the canal, I will think I have attained my object. Before trying to solve this question, I may as well ask what measures Government has adopted or will adopt for the safety of those who inhabit the right side of the canal. To answer the first question which I have started, *viz.*, why the inhabitants of the left side of the canal do not avail themselves of canal water, we should see whether the irrigation by means of canal water is cheaper than the old *pain* system or otherwise. Secondly, which of the two is the most convenient ? And thirdly, which of the two is more suited to the soil of the district. In order to know

which of the two system is cheaper, we must have a clear idea of the scale of expenditure incurred by the tenants in irrigating their crops according to both the methods.

The following are the rates of *puttas* which the tenants execute before they are entitled to take water from the canal :—

	Rs.	As.
Sugar-cane field	3	2
Rice field	1	14
Rabi crop	1	9
Opium field	1	9

So that sometimes the tenants have to pay to Government for the irrigation of their land an amount equal to the rent of the land itself. Irrigation through *pains* was decidedly cheaper than this. Zemindars and rayats were to be only a little careful in clearing out the mouths of the *pains*, and everything was done. Every mouzah had its own indisputed *pain* to gain free admittance to the river at the time of inundation. Zemindars, in order to derive greater advantages from the river water, dug the *pain* deep, and thus the slightest rise of water served to irrigate their fields.

But now this cheap system of irrigation is gone, I may say, gone for ever.

A rayat possessing a beegah of paddy land must necessarily irrigate it at least three times if there is a scarcity of rain. But if the natural rainfall is in abundance, there is no need of doing this so often. Coming again to the *bundh* system I should say, as I have already said above, that the irrigation of a beegah of land is only a matter of a penny or two. Though at first this may look somewhat exaggeratory; but it is a fact beyond all doubt as I will presently show. A firm *bundh* in the Punpun which cost Rs. 700 irrigated innumerable beegahs of land. These *bundhs* were never prepared only by one zemindar; but they were the results of the joint effort of many. Suppose (and the supposition will be very near the truth) that ten *mouzahs*, each in average consisting the area of 5 beegahs of land, on each side of the river were benefited by the out-flow of water through the *pains*. Now the cost of it though at first appears to be considerable, amounting to something like Rs. 700, would be reduced to annas and *pies* when divided among the above large number. This out-flow of water, besides serving the purpose of *khareef* did good also to the *rabi* crop.

The aim of Government is decidedly laudable; but somehow or other the good intention is lost in its execution, and what might have been a boon, often becomes, through mismanagements and havocs of the patrols, and the petty amlahs of the department a source of real grievance. After the tenants have legally executed the *patta*, they as a matter of justice, are entitled to irrigate the crop at the proper time. We do not blame Government but the poor tenants, owing to some mysterious causes do not get water in time. You can well imagine Sir, the chagrine, of a poor tenant, who sees the green *khareef*, his wealth and everything for him, turning pale for want of water, for which he has already paid. Though he has legally paid for it, yet he does not get water, at the proper season, unless he does a bit of *khoshamud*, if not something substantial to the petty canal lords. Sometimes the patrols and other petty *amlahs* intentionally open some of the *nalas* and thus cause the water to flow out. They make this the ground of a threat to the ignorant rayats and impute the mischief to them, which coming before a court of justice becomes, owing to many causes difficult to be disproved, and these amlahs make a good bargain for themselves from the job. The *rabi* crop to some certain extent is indebted to the canal water, because we can have the prospects of a rich *rabi*, even if there is no rainfall. But we cannot possibly have a rich *khareef* if the rain is not in abundance.

I hope to resume this subject in a future issue.

VILLAGER.

The Indian Agriculturist.

CALCUTTA, *OCTOBER* 1, 1881.

TEA COMPANIES.

A RETURN has recently been issued by the "Planters' Stores and Agency Company, Limited," of the results of the working of eleven tea companies having their offices in London, from which a considerable amount of information is available. A careful perusal of this document shows conclusively why some companies are paying dividends and others are working at a loss. The table gives details for each company; we shall here deal with the averages of the eleven companies :—

			1879.	1880.
Gross price of tea per lb. including all receipts	...	*d.*	17·37	14·41
Cost of making per lb. including all charges	...	*d.*	16·03	14·18
Profit per lb. of tea	...	*d.*	1·34	0·23
Dividends paid	...	%	4·77	3·07
Yield of tea per acre	...	lbs.	...	349
Capital employed per acre		£	...	87
Capital per maund of tea maunds	...	£	...	21

To any one who has studied the financing of tea concerns, this table speaks in language not to be mistaken. Here we have an average cost per pound for making for the two years of 15·10*d.* while the price realised averages only 15·89*d.* leaving a profit of only ·79*d.* per lb. The cost of making in individual gardens runs from 12·25*d.* to 17·62*d.*; the prices realised were from 9·12*d.*, to 19·37*d.*, and the results per lb. from—4·12*d* to+·25 to 5·12*d.* Now we can understand without much difficulty why two gardens making an equal quality and having an equal outturn of net profit, should pay different dividends, as those, depend on the amount of capital invested : but after allowing for local peculiarities in the way of expense, we are at a loss to understand why there should be such vast differences in the cost of manufacture. It is no doubt true that a large garden can be worked cheaper per lb. or per acre than a small one, many of the items being constant, but these gardens under notice are all pretty large concerns. We also know that a garden yielding 470lbs. of tea per acre, costs less relatively than one yielding only 192lbs. These latter figures depend, then, on management, and by management we do not use the term in its narrow meaning as referring to the garden management. We do not think the garden management is so often at fault, as there is an *esprit de corps* which impels managers to try their very best. By management, we use the term in the sense of control. If gardens were, first of all, carefully provided with good managers, the proper plan would be to give these gentlemen reasonable discretionary powers, and allow them to do their best, without being hampered by instructions from directors or managing agents, who may be good business men, but who, in many instances, have little practical experience of tea planting and manufacture.

The difference between the selling prices of 1879 and 1880, *viz.*, 2·96*d.* per lb., is accounted for by the extremely low market ruling in the latter year. The minimum should be 18*d.* or say 12 annas, and in 1879 it nearly rose to that. On the other hand, a useful lesson is learned by looking into the difference between the cost of making in the two years, which amounted to 1·85*d.* On this head 8 annas or 12*d.* ought to suffice, and a little more economy exercised in the direction of office charges would reduce the price to that figure. The column containing dividends is slightly misleading; it does not contain dividends earned, but dividends paid, and as some are guaranteed, the column does not give a true idea of the profits made. Perhaps the fairest mode of estimating this is to work out the profit made per acre. We hold that by proper management and control a fairly worked garden should give Rs. 100 profit per acre per annum. The Borelli, one on the list before us, made 470lbs. of tea, and made a profit of 5·125*d.* per lb. This at par is exactly £10-0-8¾ per acre, and, given an ordinary good market, we see no reason why this should not be the rule, rather than the exception.

Let us now look at the capital account of those eleven gardens. The figures are given in pounds sterling per acre, a very good method for purposes of comparison. These range from £27 (Jorehaut Co.) to £160 (Eastern Assam Co.), the average being £87. Now we have got reasons for the opinion that £50 is amply sufficient to bring a garden to paying point. How then have some gardens been made for £27, while others have cost £160 per acre? In the early days of the industry, there was no thought of economy; where a speculation was popularly supposed to yield 300 per cent., there was no incentive to saving. Money was recklessly thrown away on land and on establishment, while promoters made fabulous sums. The crisis of 1866 brought all this to an end. Some companies struggled through and are still existing, but being burdened with their original enormous cost, can never hope to pay

reasonable dividends; while others succumbed, and new proprietors bought them for a tithe of their cost. Those gardens weighted with excess capital should have this written off. When dividends on the reduced capital could be made, shareholders could not lose by striking off half of their capital and accepting one share for two or three, as the dividends would remain the same absolutely. Another mode of overcoming the difficulty is to pay no dividends, but utilise all profits in extending. Say a garden has 300 acres and its capital is £30,000; let the annual profits be used in extension till the garden consists of 600 acres, when the capital value would be £50 per acre. By this mode the shareholders would lose nothing. Now they would get no annual dividends, but the value of their scrip would steadily rise year by year.

Another column contains the amount of capital invested for each maund of tea produced annually. This ranges from £6 (Assam Co.) to £50 (British India), and the average is £21. Allowing a garden to cost £50, and the outturn to be 400lbs. per acre, this sum should never exceed £10. To bring this estimate within reasonable bounds, the outturn must be good, and the invested capital low, and this brings us to consider the last item in the list, *viz.*, the outturn per acre. In the list before us this item ranges from 192lbs. (British India Co.), to 470lbs. (Borelli Co.), and averages 349lbs., a very fair average indeed. Keeping out four of the lowest companies, the average of the other seven is 406lbs., proving that our estimate of 400lbs., is not Utopian. We might insist on a much higher average, but are now only concerned with the figures before us. If one company can make 470lbs. per acre, there exists no good reason why others should not also do so. Any cause which operates against this must be either concerned with finances or bad management, or perhaps both. It is perfectly foolish of companies to go on making half of what they ought to do. If the management be at fault—change it; if the directors—change them; and if the cause be want of funds, why, sell the concern and get out of it what may be, rather than drag on a ruinous and bankrupt concern.

EMIGRATION TO THE TEA DISTRICTS.

THE Indian Tea Association has been in communication with the Government of India on the subject of the proposed amendment of the Labour Districts Emigration Act VII. (B.C.) of 1873. The draft Bill, it will be remembered was prepared by a mixed Committee composed of officials, a representative for the Tea Managing Agents of Calcutta, and an experienced tea-planter from Cachar. The draft Bill has now been before the Government of India for some time, having been handed up by the Government of Bengal. The object of the correspondence was to endeavour to induce the Government of India, to pass the Bill before the Simla season closed, the winter season being the most suitable for recruiting. The Indian Tea Association has received the following reply, dated Simla August 18:—"I am directed to acknowledge the receipt of your letter, dated the 6th instant, in which you urge, on behalf of the Committee of the Indian Tea Association, the expediency of the Assam and Chittagong Emigration Bill being passed into law at an early date.

2. In reply, I am directed to say that the Government of India will employ all means in their power to expedite the passing of the Bill, and that it will, if possible, be passed at Simla. I am, however, to add that it is not probable that the measure will be ready for enactment before October next."

We trust the Bill will become law early in October, as it would in many cases save an entire year, to have it passed in time, for the recruiting season, which commences usually in September. There are one or two points which we may notice here in connection with this Bill. It is proposed to give planters power to arrest coolies without a magistrate's warrant. This provision seems to have occupied the attention of the Viceregal Council. It is no doubt a very important provision, and directly invades the liberty of the subject. There are, however, circumstances connected with the contract between planters and coolies, which render special legislation in this direction advisable, if not imperatively necessary. Planters are frequently situated at a great distance from the magistrate's office, and if they must apply for a warrant before detaining a coolie who is bent on breaking his contract by bolting, they may as well let the man go: for before they have obtained their warrant, the run away may be a hundred miles off and beyond the magistrate's jurisdiction. There are other points in connection with this amended Bill which we noticed when the draft was submitted to the Lieutenant-Governor by the Committee, and which do not require further notice here. When a Bill is sent up before the Council, it is usual to append to it a series of reasons and objects, showing what is sought to be obtained by the Bill; and in connection with protective legislation of this sort, the great point has hitherto been the protection of the poor coolie. In his letter to the Government of India, the Honorary Secretary to the Indian Tea Association says: "Nor is such registration at all necessary for the protection of the locally engaged laborer, who, as pointed out by the Government of Bengal, and as the Committee know from their own experience, is thoroughly well acquainted with his rights and privileges, and perfectly able to take care of himself in any engagement he may enter into." The truth of this statement will not be called in question by any one who understands the subject thoroughly, and who has been for years in charge of such coolies. It is therefore with much satisfaction that we observe a departure from the time-honoured principle of protecting a man who has been shewn to be perfectly able to look after his own interests. One prevailing principle observable in this draft Amended Bill, is the protection of the employer. This latter individual has been groaning for years under the crushing protection afforded to the labourer, at the expense of the employer, and we are pleased to see a change coming over the system. It may be mentioned here, also, that we do not think the provisions of this new amended Act will remain long in force. The opening up of communications between the recruiting and the tea districts will soon make the act obsolete. Coolies will soon find their way to the tea districts, when all arrangements made between them and the employers of labour will be under the ordinary provisions of the Contract Act of India. The need for special legislation will then have ceased to exist.

REBOISEMENT.

OF the many benefits which the British Government is undoubtedly bestowing upon this country not the least is the persevering effort to reboise it. There was without doubt a time when Upper India was well wooded. Indeed, we know that upon those Trans-Indus plains which are now the very perfection of hideous sterility, there stood forests of such growth as to shelter the red deer and the rhinoceros. The memoirs of Baber describe how he and his hardy Moghul followers hunted these with the glee of men who find unaccustomed game, when they first descended from the steppes of Turkestan through the savage Afghan passes into the plains of India, to found that Moghul Empire to which we have succeeded. The forests of Hindustan, however, have disappeared beneath the tramp of contending armies. West of the Jumna, wave after wave of invaders—Afghan, Moghul, Persian, Tartar, Biloch, have consumed them for the firewood of their mighty hosts. Even the people of the country struggling up to independence against enfeebled oppressors—Ghukker princes resisting the Afghan, Sikh Misls defying the Moghul—have not spared the ancient witnesses of their ruin, their despair, and their resistance. The giant trees which had stood through centuries amid this whirl of conflict, with branches stretched toward Heaven as if in prayer for the deliverance of the land from its oppressors, have fallen to the greatest extent by the ungrateful axe of the sons of the soil. Traditions are rife of the vandalisms perpetrated by the Sikhs. Mighty plane trees, whole groves of mulberries and mangoes, cleared off for firewood or to root the huts of their temporary camps. East of the Jumna again the Mahratta and Pindari swarms followed the same *rôle*. During the break-up of the Moghul Empire, Hindustan was a wild and tossing chaos, torn and convulsed by the struggles of dynasties for the mastery. Principalities were erected with incredible rapidity by successful leaders, only to fall to pieces the next moment, while other warrior chiefs built up petty

sovereignties out of their *débris*. Vast torrents of desolation poured down from time to time from the Afghan mountains or from the highlands of the Mahrattas. And over the whole there spread ceaseless the curse of the Pindari hordes, eating up, like the locust, every green thing. Such were necessarily bad days for the peaceful trees, and they fell to the axe of the destroyer. The provinces between the Son and Jumna were stripped as bare as the Punjab; Oudh and Behar only escaped through the approach of the foreigners from the East. But the day of the trees was to return. Their avenger was not far off—the red line advanced further and further on the map and a belt of green followed it.

Wherever the Englishman has placed his foot trees have sprung up; first around his habitation, then on the roads radiating therefrom, then in groves at places where he is wont to camp, lastly round about among the villages, whose inhabitants, settling down into prosperous agriculture under his ægis, recall to mind the ancient pleasures of coolness and shade, and the profits of fruit and timber. Finally the Government took up arboriculture on a system. It has become a department. Now, in the territories under the Government of Allahabad at any rate, the smiling *paysage* of the old Hindoo days bids fair to return, and Dryad and Hamadryad will soon visit their ancient homes and inhabit the cool shade of frequent groves. The Department of Agriculture in that province gives but a few lines in its report for last year to the description of its exertions, but the results we gather therefrom are indeed gratifying to those who believe in reboisement as one of the first necessities in this country for protection against both pestilence and famine. "Out of 2,500 miles of public road in the North-Western Provinces and Oudh, about 590 miles are every year under arboricultural operations, involving the maintenance of about 500,000 trees. Upwards of 200,000 plants are every year planted out on roads from the nurseries, most of which are fruit and fodder producing. Without special reasons no other trees are allowed to be planted. These plants are raised in 110 nurseries scattered all over the province. Groves are also planted here and there, and instructions have been given for their establishment on an extensive scale in the Jhansi division, which is most deficient in trees. Private persons have also been encouraged to plant trees on road sides with the privilege of taking the fruit and dead wood, and in some districts they have come forward to do so with alacrity.

* * * * *

Besides avenues on public roads, opportunity is taken to interest private persons in horticultural operations by supplying them with seeds and plants from public gardens free of, or at a nominal cost, by giving instructions for planting, and by explaining to them the benefits of tree planting."

This stage of progress has not yet been attained in the Punjab. In fact the success in respect of arboriculture of the North-Western Provinces is entirely owing to an individual, Mr. Buck, and no Mr. Buck has as yet arisen in the next province. In the Punjab, arboriculture is left to the idiosyncrasy of the district officer, and to the spasmodic efforts of tehsildars. It is paid for from the district funds, and more or less money is devoted to it accordingly as these officials are inclined to the saddle or the chair. Even where sufficient funds are applied to arboriculture, they are apt to be greatly wasted. A grant for way-side trees very probably becomes a fund to support in happy idleness, as bheesties and chuprassies, various hangers-on of the tehsil establishment. It is generally reckoned that every tree brought to maturity on a district road has cost ten rupees, and at this rate it is evident that many years must elapse before the Punjab will present the appearance that the N.-W.P. presented even twenty years ago. But there can be little question of the far greater need of the Punjab. The stations there are generally fairly wooded, but reach the outskirts of most of them and then gaze out astonished at the howling wilderness beyond you: undoubtedly, when the autumn and spring crops are on the ground, the plain, though treeless, looks green and fertile. When the crops are cut, however, gazing over the barren expanse, no one would ever imagine that anything grew thereon. The plain stretches for miles to the horizon, bare, desolate, treeless, or if a few trees are to be seen, they are the tamarisk and kikar which are by no means calculated to take off from the aspect of desolation. Of course there are districts like Delhi or Hoshiarpore, to which this description does not apply; but on the other hand there are many, such as Montgomery or Sirsa or Dehra Ismail Khan, for which it is not half bad enough.

Arboriculture, then, in the Punjab, should be taken up on a system as in the N.-W. P. and Oudh. A central authority should, like Mr. Buck under the Government of Allahabad, prescribe a systematic method of planting and maintenance. It is evident, when we consider the small amount of means available in the Punjab, that the great outlay necessary for growing avenues generally along all the public roads cannot be undertaken. No doubt with care and supervision, the trees could be brought to maturity at an average rate of two rupees or even less. We refer to fruit or fodder producing trees, as in the N.-W.P. But this money can be laid out to better purpose in groves, and for the road sides it should suffice, except in the immediate vicinity of head-quarter and tehsil stations, to plant tamarisk cuttings and sow kikar seed on the trench system. Trenches averaging two feet deep and three feet wide should be dug on each side of district roads, the earth being used to raise the centre of *kutcha* roads or to spread over the cesses of *pucca* ones. In these should be stuck double rows of tamarisk cuttings, or kikar seed sown broadcast in the autumn. The operation costs little, and no further attention is required Ninety per cent. of the seeds or cuttings may fail, or be destroyed by goats and cattle, and yet the results are profitable Of course gaps caused by such failures should be filled up yearly with more cuttings and more seed. Near stations, where better trees are planted, the best known method is that of borrow-pits, connected by small, shallow trenches.

The main strength of the Arboricultural Department in the Punjab should, however, contrary to the N.-W. P. system, be devoted to the planting of groves. For these, waste patches of land can everywhere be found, which either belong to the Government or can be acquired at small cost. It must indeed be a bad soil which will not grow some kind of tree. For these, irrigation is required, and must be obtained either from a canal or by construction of wells. Evidently this initial expense and the keeping up of the wells for the irrigation of the groves, is a very different thing from the watering of miles of roadside trees by bheesties. Where a road-side tree costs a rupee, a grove tree costs a pie, or less. Certainly the advantage of shade for travellers is lost, but this is a very minor object. To dot a country with groves must in every other respect offer all the advantages obtained in traversing it with long lines of trees. The first object in either case is to encourage tree planting by the people, and this is to be attained by shewing them that tree-planting is profitable, which is best demonstrated by groves, and that it is advantageous and agreeable in respect of the shade afforded, the food and fodder yielded, the wood supplied for fuel, thus releasing the cowdung for manure, and finally of the power of the trees to attract and retain moisture. A department working on this system and by means of a native extra assistant in each district specially told off to superintend the district operations in communication with the superintendent of arboriculture, would soon cover the Punjab with groves and border the long lines of arid road with a fringe of useful timber and fuel-producing trees.

NOTES FROM A COTTAGE GARDENER.

"THE HYACINTH."

(Communicated.)

As it will soon be the season for potting and planting these sweet-scented and lovely spring flowers, a few hints on the best mode of cultivating them will be found useful. They are grown in three ways, namely in glasses filled with water, in pots, and in beds in the open ground.

In Glasses.—Whenever you have the opportunity, choose your own bulbs, or deal with a trustworthy man. Select such as are of a middling size, of a close, compact, round form, without offsets at the bottom; also notice that the apex or the top of the bulb is full and firm. There are now several kinds of glasses, some made of

clear glass, and in old-fashioned shape; others of the same shape, but with the glass of various colors; and there are others of the more recent fashion with the lower part bell-shaped. Where fancy rules, it is difficult to decide on which to fix. I am, however, inclined to the first named; namely, those upright ones made of clear glass. It may be said with truth of this form and make, that the roots and the water are better seen, and of course if anything be wrong, it can sooner be set right. Be the choice as it may, now is the time to procure the roots and the glasses. Fill the glasses with clear rain water or soft water, and place the bulbs in the cup at the top of the glass, taking care that they are not in actual contact with the water, I would say, let the thickness of a shilling be between the bottom of each bulb and the top of the water. The roots will quickly push and find their way down in the water. Then place them in a dark and cool room, where the temperature is pretty nearly of an even character. Let them remain here until the roots have grown downwards nearly to the bottom of each glass.

If they are then examined at the roots, they will generally be found covered with a greenish slime, and the water will be dirty. In that case draw the roots carefully out of each glass, throw away the water, wash the glasses quite clean inside and out, refill them with fresh, clear, soft water, and then wash off carefully the green slimy matter, leaving the roots as white as snow. This washing must be carefully done, so as not to break or bruise any of the roots. When once done effectually, they will not require washing again. The water should be changed once every week or ten days. With this slight attention good healthy bulbs will produce very fair flowers, and will ornament the parlour window for a considerable time, the bulbs, however, will suffer considerably by this water culture. The only thing the amateur can do is to turn them out of the glasses, and lay them in by the heels in the open ground in some shady border. They will here ripen their bulbs, and will do to plant in the mixed border the following season.

In Pots.—The soil for hyacinth in pots should be rich and firm. Turfy loam two-thirds, and well decomposed cow-dung, at least two years old, one-third will form as good stuff as needs be for them, and it will be an improvement if a liberal sprinkling of sharp river sand be added. The pots for hyacinths are deeper and more upright than ordinary, but they will do very well five inches in diameter, place one bulb in each. If more than one is put into one pot, the size must be proportionably larger. In potting lay an oyster-shell or a piece of broken pot over the hole; then put in about an inch of soil, press it down very firm, then add a second inch, and press it down firmly also, and so proceed till the pot is nearly full. Then place the bulb upon the soil, and add soil enough to just cover it, excepting the very apex of the bulb. To keep the bulb from rising up (which it will do, or rather the roots as they spring forth will lift the bulb up), press the soil around it even more harder than that under it. I have always found this hard pressing of service. It prevents the roots from quickly rushing down to the bottom of the pot, thus giving them time to gather up nourishment during their descent.

The season for potting is as early in October as may be convenient. For a succession a second batch might be potted towards the end of November.

As soon as they are potted, place the pots in a bed in neat straight lines, and cover them over with sifted ashes or rotten tanner's bark, or even sawdust would do (though I think ashes the best), three or four inches deep. Here they are to remain to form roots and just start in growth. Then take a portion out at a time, wash the pots, clear off the ashes, and place them in a little warmer spot. Whilst here, they should be freely watered, and the flower-stems supported with neat green sticks or wire supports.

As soon as the blooming season is over, the pots should be removed into a favourable situation, and there be plunged quite overhead in the ordinary soil, continue to water them freely, and thus the bulbs will be regularly fed, and will become very fair plants for borders the following year.

NATIVE AGRICULTURAL EXPERIMENTS.

Communicated.

At about three miles from Ghyali, there are two villages called Aroon and Thathangoody. In these villages my father purchased 15 years ago 144¾ acres of land, for Rs. 15,000, of which 85 acres are in Aroon and 59¾ acres are in Thathangoody.

The village Aroon consists of 193¼ acres in extent, whereof 180 acres are wet lands, while the remaining 13¼ acres consist of 2 or 3 elevated patches taken up for habitation, &c.

And the village Thathangoody consists of 135 acres, of which 130 acres are wet lands, and the remaining 5 acres being taken up for habitation, &c.

The village Aroon is somewhat better irrigated by a channel branching from the river Colleroom (a branch of Cauvery) than the village Thathangoody, which has only a very precarious and uncertain supply of water from a channel branching from a drainage river called Palavar.

The soil in both the villages from the surface to a depth of 4 or 5ft. is of dense clay, and the subsoil below is sandy. A thin flow of subterranean water in the sand, below a depth of 6 or 8ft. from the surface is obtainable during the hot season.

These lands from the time of purchase, are scarcely yielding any margin of profit, and as many other villages are labouring under similar difficulties, and reference into the accounts of the past years, showed that the yield has been gradually declining, I determined to take up the cultivation of the lands in Aroon and Thathangoody villages, under my direct management, and ascertain experimentally what could be done to remedy the evils.

I herein give a regular description of the routine practices of agriculture followed in this taluq and generally in the district.

The wet lands as a rule are given to the under-tenants or Porakudies, who cultivate for varum (a share in the produce) and the varum in these villages is 30 per cent. of the produce.

In addition to the abovementioned varum, they also enjoy a piece of land as *Inam*, and hold punya lands or dry lands if there be any, on a low rent.

During the season of cultivation they get a premium of paddy, for seeds and wages, and the amount of these items is deducted from their varum, payable on the outturn of their labours.

Some servants as Thotti, water-man, carpenter, black-smith, &c., and some institutions as pagoda, Bramin, priesthood, &c., are maintained both by *Inam*, and also by a share in the produce.

From the month of August the supply of water is obtained from the river, and the tenants or Porakudies, after a period of rest, during the hot season, get a loan from the Merasdar to purchase the cattle gapped out in the previous year, and get some wood and purchase a mammatti blade from the bazaar, and carry them to the carpenter and blacksmith who makes and give them mammatti and plough.

In the month of August the seed beds of kar varieties are watered, ploughed, and kar seeds sown.

In September the kar varieties are transplanted, and the seeds of sumba varieties are sown. The kar fields form only ⅙th or ⅛th of the extent of the wet lands in the village, and the rest are transplanted with sumba varieties, and sumba transplantation extends over October, November, and December.

In November and December the kar varieties are harvested, and in February and March the sumba varieties are harvested.

Three to four ploughings are given for the puddling, and no manuring is practised, and the paddy plants are weeded once.

This system has long been in practice and has produced several evils.

The Porakudies and servants who were almost slaves in former days, have gradually grown idle by the abolition of slavery by the British Government, and have neglected their duties because they have no corporal punishment as they had before. The yield of the land became gradually reduced, and it now ranges only in such amounts that it is scarcely possible for a Porakudie even to pay back the stipulated advance he obtains from the Merasdar during the cultivation.

The following accounts of a Porakudie, shows the condition in which the agricultural labourers in the taluq stand.

A Porakudie cultivates with a pair of cattle 4 acres of wet land, and the yield of 4 acres ranges on average from 80 to 90 kulums, therefore the share or varum of the Porakudie ranges from 25 to 30 kulums.

For these the items of advances they get are as follows:—

Seeds at 2¼ kulums an acre	...	...	10 kulums
Cultivation, expenses at 2 ditto	...	...	8 "
New year's day, &c., festivals	...	...	3 "
Total		...	21 "

The remaining 5 to 10 kulums he gets at the harvest, but he recklessly spends at the very harvest season, this 5 to 10 kulums together with 5 to 10 kulums which he could get from the *Inam* lands.

Thus if the yearly account of a Porakudie were to be settled, taking the loans he gets for cattle purchase, marriage, &c., into consideration it could leave no margin of profit, but only leave an addition to their old debt.

Therefore the annual income of tenant or Porakuli including the *Inam* and wages, will never exceed 30 or 35 kulums, unless he gets something more by petty thefts and pilfering. Consequently the Porakudies are no better than the cattle, and they really starve bitterly for many months, as they recklessly consume away the little stock they secure during the harvest season.

Thus in the whole of my estate, I can find only a very few Porakudies who are not indebted to me in hundreds of rupees.

I find it an universal custom with the Porakudies to appropriate for their own private use, a portion of the seed, and cattle purchase money in collusion with the village agents, and sow the nursery thin, and purchase worthless cattle unfit for work, which scarcely last for a single year. Consequently the death of the cattle comes up in every year to an awful percentage, and I am obliged to spend annually a large sum of money in cattle purchase.

Consequently the Porakudie system rendered the working class ignorant negligent and untrustworthy paupers, and I find it totally impossible to attempt any improvement without altering the present system.

In the year 1879 I attempted to abolish the Porakudie system in the Aroon and Thathangoody villages, as they are situated at a convenient distance from my place of residence, and at the same time as they are not in the centre of my villages to tend to the creation of any unpleasant feeling on the part of the labourers, likely to lead to general confusion in other villages at the outset.

I relieved the working class from the worthless contract, and brought them as daily labourers, allowing them the enjoyment of the *Inam* lands.

I withdrew the *Inam* of the servants, and the pagoda and other institutions, and made them receive the monthly payment.

I took a few worthless cattle left with the Porakudies, crediting their value to their account. I constructed and purchased ploughs and other implements and appointed trustworthy agents to conduct the process of operations under my direct supervision.

I built cattle sheds and other necessary buildings, regulated myself the food for the cattle, and made arrangement for their sanitation, treatment, &c.

I now find all the cattle with the exception of those taken from the Porakudies, fit to work, with light improved ploughs and with carts, and the awful percentage of their mortality is not felt for the last two years.

The following table shows the total outturn and cultivation, expenses of the Aroon and Thathangoody villages for the past 15 years :—

The Total Produce.

Year.		Paddy in kulums of 24 Madras measure.	Market value per kulum.			Money value			Value of straw, manure, &c.			Total.

As both the villages Aroon and Thathangoody lie close together, the cultivation operations are carried on as if they are one and the same village.

In 1880 the village Thathangoody as almost in every year, suffered severely from want of water during September and the early part of October, just at the time of transplanting, and the fields became thoroughly dried and cracked.

Thus the average yield per acre in the village Aroon is 27$\frac{3}{8}$ kulums, and 27 loads of straw worth Rs. 28-14, and the average yield of the village Thathangoody is 12½ kulums of paddy, and 9½ loads of straw worth Rs. 13-1 per load. The cultivation expens. inclusive of kist, for both the villages, Rs. 20-0-3 per acre. Therefore the loss per acre in the Thathangoody village is Rs. 6-14-9, and the profit per acre, in the Aroon village, is Rs. 7-2-9, and therefore the profit on the whole for both the villages is only Rs. 2-7-10½ per acre.

The Field Experiments.

The experiments conducted this year include the determination on the effect of—

(1.) Deep cultivation and inversion of soil.
(2.) Farmyard manure.
(3.) Bone ash.

The paddy in the wet lands, is the crop on which the experiments were made.

I was able to conduct only a very few experiments this year, because

(1.) Much of my time and attention was spent in bringing the labourers in the experimental village to proper order, they totally disliking their idle system to be altered.

(2.) The wet lands in the experimental village as most other villages in the taluq suffered severely both from draught during September, and submersion during December, owing to the imperfect arrangement of irrigation and total absence of drainage.

None of the fields experimented were manured in the previous years.

Cost of Cultivation.

The data given below concerning the cost of cultivation has been determined by actual measurements, and represents the cost per acre of each operation, carried on by higher labour under supervision not of a very strict nature.

1st of Operations.	Per acre. Rs.	As.	P.
Ploughing by light improved iron plough ...	1	12	0
Ditto by the country plough for the 1st ploughing	1	11	0
Ditto by the country plough for the 2nd, 3rd, and 4th ploughing ...	0	12	0
Raising the seedlings	0	8	0
Digging and bordering	0	6	4
Transplantation	0	7	9
Weeding	0	4	7
Irrigation	0	4	5
Harvest	2	6	0
Inam	0	14	0
Sundries	0	10	1
Superintendence	2	1	9

2nd of Manures.	Rs.	As.	
Farmyard manure	0	5	per cartload.
Bone ash	2	8	„ candy or 500 lbs.
Kar seed	1	4	„ kulum.
Gambra seed	1	10	„

One kulum of Tanjore is equal to 24 Madras measure or Avois, 72 lbs.

EDITORIAL NOTES.

WE publish in another column a letter which has been addressed to the Calcutta Chamber of Commerce on the subject of the imposition by the Chinese of certain duties on opium in some of the treaty ports, which are unauthorised by the Treaty of Tientsin. The importers contend, and their position is unassailable, that under the treaty a tax of 30 taels a picul, or about Rs. 115 per chest, and no other tax whatever, is leviable upon opium within a treaty port. But it is said that the Chinese have imposed, or are about to impose, duties which will amount (together with the lawful Rs. 115) to Rs. 874. The moment the opium gets outside the premises of the importers, it is held to be liable to these extra duties. This position is of course entirely indefensible. The opium cannot be made liable to any extra duty until it has got, not merely outside the importers' premises, but outside the treaty port, without a breach of treaty. How far the Chefoo Convention would justify the action of the Chinese authorities is not a relevant question, so long as that convention is unratified, and it is as plain as possible that the Chinese are just as well aware as the opium importers are that they are breaking the treaty. It will take a long time, however, and will cost a deal of trouble, to get the wrong rectified, and in the meantime the officials will be able to collect large sums in this high-handed way. As Messrs. Herton & Co. observe, this action of the Chinese officials will probably be ascribed by the Anti-opium League to their desire to discourage the importation and consumption of opium. These Chinese officials, we shall be told, see with anguish the evils which the vice of opium-smoking is working among the people, and, as Britain will force opium upon them, they are doing what they can to put it beyond the reach of the people. But the explanation which Messrs. Herton & Co. give of the motives of the Chinese authorities is, we fear, the true one, and though the Indian drug may be put beyond the reach of many who use opium, the effect will only be to compel them to use the native article. It does not appear, however, that the most vexed questions connected with the opium trade need be raised in connection with Messrs. Herton's letter. Whatever our views on these questions may be, we cannot help seeing that the opium traders are within their rights in asking that the treaty be adhered to until another arrangement has taken its place. Of course the action of the Chinese must tend to lessen the demand for foreign opium, and so the opium merchants and the Government in this country are interested, as well as the importers in China. Accordingly we understand that the Calcutta Chamber of Commerce propose to bring the matter to the notice of the Government of India, and in the meantime the Chamber invite an expression of opinion on the subject from persons interested in the opium trade.

IN connection with the Assam Railway scheme, the Lieutenant-Governor said that an effort would be made to induce the offer of local capital, especially from natives. There is no reason why such work should not be taken up almost entirely by native capitalists, except the potent one of want of patriotism. We can thoroughly understand the wealthy native who refuses to advance his captial on the chance of obtaining four or five per cent. when, by lending it among his own people he can obtain from 12 to 36 per cent. for it. There is, however, another way of looking at it. When a railway runs through a district, the value of land and other property is materially improved, a demand is created for land, rents rise, and the

position of the owner is very much improved. A consideration of this fact should induce wealthy zemindars to invest largely in such schemes, looking on them as they would on extensive drainage or other schemes for land improvement purposes. This is where their want of patriotism is shewn, and where a total absence of other than purely selfish motives is the controlling power, one cannot look for broad statesmanlike views to be taken. At home, commercial men support such schemes from motives of a mere secondary nature. A man will invest largely in a railway which does not go near his land, but which is calculated to improve trade and commerce generally, he hoping to benefit more in that way than in dividends. A strong effort should however be made to point this out to wealthy zemindars, and if possible the capital of our railways should in future be raised here, when loss by exchange would largely be done away with.

IN this connection, we may notice a proposal to run a line from Balagunge to Luckeepore on the frontier of Munneepore, by way of Sylhet and Silchar. We do not approve of this scheme. It necessitates crossing the Khooseara at Bungha just below the point where the Barak bifurcates in the Soorma and the Khooseara, and the Barak a little above the sudder station of Silchar. The Assam Railway, as proposed by the deputation who waited on the Lieutenant-Governor last week, on the other hand provides for both Cachar and Assam Proper, and avoids all the large rivers except the Megna, which would be crossed at Goalundo. Another objection to the Soorma Valley line is the fact that it provides for a steamer between Goalundo and Balagunge, which would always take four days at least, and would continually lead to irregularity in timing. It would, besides, be utterly impossible to adapt it to any extension by way of Assam Proper. We trust that the Goalundo and Mymensing line will be prosecuted with energy, and that the two extensions towards the Brahmapootra and Soorma Valleys will not be lost sight of. The best route for the latter will be to get to the Terai at the foot of the Garrow, Khossia, and Jaintia hills soon after leaving Mymensing. The Sylhet station would then be in the town of Sylhet, while the Cachar line would pass opposite the sudder station of Silchar. The rivers between these two stations are not very large, *viz.*, the Looba and the Jatinga, and could be bridged without an extravagant expense.

AN American paper has the following :—

The inhabitants of Great Britain are making steady continuous inroads upon their hitherto waste lands. The cultivated area in 1880 was 32,101,909 acres, as compared with 29,727,047 acres in 1867 ; between 1879 and last year about 26,000 acres were brought into cultivation ; in previous years the average advance had been from 100,000 to 150,000 acres. So far this is encouraging. What we have heard from the farmers now for some years prepares us to find that the acreage under corn (including beans and peas) is slowly decreasing, and whereas it was 9,234,780 acres in 1867, it was 8,875,702 last year. In green crops the diminution has been slighter in the same period, namely, from 3,498,163 acres to 3,476,653. Hay and rotation grasses show an increase from 3,989,974 to 4,431,339 ; and permanent pasture from 11,136,036 fifteen years ago to 14,426,959 acres last year. Market gardens have made a satisfactory advance, showing that increasing attention is being paid to the small cultures ; the acreage has increased from 36,201 in 1872 to 44,490 in 1880. The area under orchards has fallen off from 206,583 in 1871 to 189,596 acres in 1880. So far as the statistics of live stock can be depended upon, the number of agricultural horses is slightly less than last year ; cattle have increased, and number nearly six millions ; sheep have decreased from 28,157,030 to 26,619,050 ; and pigs from 2,091,559 to 2,000,842. In Ireland, on the other hand, ground has gone out of cultivation, the quantity being about 180,000 acres less in 1880 than in 1876. All the principal crops have slightly diminished, and the cattle have increased in number ; but both sheep and pig are becoming fewer in number in Ireland :—

THE Punjab Government have passed the following remarks on the report of the Superintendent of the Agri-Horticultural Society's Garden, Lahore, for the year 1880-81 ;—The experiments in arboriculture have to some extent shown what trees are suited for the Punjab, and the best methods of growing them. So far it seems probable that the Rain-tree cannot stand the cold of this province, but steady progress is being made in the distribution of Eucalyptus plants and seed, and the success of the experiments made in grafting the European olive is satisfactory.

2. The experiments with oats and wheat from America are interesting, but a better judgment could have been formed as to the results, if the area sown, mode of cultivation, and yield, however poor, had been stated with greater exactness ; and the Lieutenant-Governor would like to receive fuller details in future regarding experiments in raising new staples, and trials of new implements.

3. The increasing number of plants sent out by the garden is an evidence of its usefulness His honor observes that the financial working of the year is satisfactory, and that Mr. Spooner deserves credit for his management of the gardens.

SOME idea may be formed of the traffic in vegetables in England from a return of one of the Railway Companies, the Great Eastern Railway Company. This company carried between the 14th June and the 8th August of the present year no less than 3,407 tons of green peas. Although this figure is enormous, it is stated that it falls short of the return for the corresponding period of 1880, by 2,460 tons, the decrease in the current year being attributed to failure of the pea crop owing to the hot dry season.

THE following is from an American agricultural journal.

The census bulletin on agriculture just issued shows that the past ten years have been the most remarkable period of agricultural growth in the history of the country. The entire cereal product of the United States has made the enormous advance of nearly one hundred per cent. During the preceding decade the increase was but 12 per cent., while between 1850 and 1860 it was 43 per cent. The yield of wheat alone has advanced from 287,000,000 to 456,000,000 bushels, a gain of 73 per cent., while the product of Indian corn has sprung from 760,000,000 to 1,772,000,000 bushels, an increase of 133 per cent. The enormous productive capacity of the great West and North-West is shown by the fact that seven-tenths of the entire wheat crop of the United States is grown in the States of Illinois, Indiana, Ohio, Michigan, Minnesota, Iowa, California, and Wisconsin ; while the three States, Illinois, Iowa, and Missouri together produced in 1879—the year covered by the census returns—upward of eight hundred million bushels of corn, or more than the yield of the entire country in 1869. Verily the United States will be able not only to feed its own rapidly multiplying people, but also to supply Europe with bread and meat whenever needed.

AN American journal the *Ohio Farmer* says :—We gave recently the comments of Mr. J. R. Dodge, on the comparison of cereal products for 1880 and 1870. From statistical tables we present the following summary, which will give a better idea of the actual increase of production :—

Cereals.	Acres in 1880.	Bushels in 1880.	Bushels in 1870.
Corn	62,326,952	1,722,909,846	760,944,549
Wheat	35,487,065	450,591,093	287,745,626
Oats	16,150,611	470,970,712	282,107,157
Barley	2,005,466	44,149,479	29,761,305
Rye	1,841,321	16,863,632	16,918,795
Buckwheat ...	851,304	11,851,738	9,821,721

An examination of the tables show but one State that produces less corn than in 1870—Maine—which in that year reported 1,089,888 bushels, and in 1880 only 960,633 bushels. The Eastern States generally shew but little comparative increase. The greatest per cent. of increase is made by Iowa, which jumps from a little less than 69 millions of bushels up above 276 millions. Illinois increases from a little less than 130 millions to nearly 328 millions. The figures for Ohio for 1870 are 67,501,144 bushels, and in 1880, 112,681,046, which is a very respectable increase, considering that but little area has been added to her cultivated lands in that period.

In wheat, several States have receded, as follows :—Arkansas, Lousiana, Massachusetts, Missisipi, Nevada, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Wisconsin. Rhode Island only raised 290 bushels, and in 1870 she reported 784

bushels. The figures for Ohio for 1880 are 46,014,869 bushels, and for 1870, 27,882,150 bushels. Ohio 'went back' on rye from 846,860 bushels in 1870 to 389,221 bushels in 1880. As explained by Mr. Dodge, the figures given cannot be taken as exact indications of progress or retrogression, for they represent but two single years a decade apart, and in many localities one or the other was an exceptional year, good or bad.

THE cultivation of the indigo plant in Europe has met with no greater success than the attempts to produce the dye artificially. The chemical production of indigo has fallen through because of the costly nature of the process and the inadequacy of the outturn for commercial purposes. For reasons somewhat similar an interesting experiment in the culture of the plant has resulted in failure. This experiment was recently made in Hungary, by a land-owning Syndicate, encouraged and assisted by the Ministry of Commerce. But the result is disappointing. According to the Pester Lloyd, a report has been issued by the Ministry of Commerce, from which it appears that the money and trouble expended on the experiment are out of all proportion to the results obtained.

THE orange crop in Kiushui, Japan, has been unusually large this year. From the two townlands of Arita and Unami, in that province, about twenty thousand boxes of fruit have been sent daily to the Osak and Kobe markets. The number of oranges in a box depends, of course, on the size of the fruits—that of the boxes being generally fixed—but we shall not be far out if we estimate it at one hundred and fifty, at which rate the consumption of the Kobe and Osaka fruit eaters would amount to some three millions of oranges per diem. But indeed eggs and oranges represent something more than mere edibles in Japan. They are messengers of courtesy, the very rank and file of that intrinsically worthless but morally inestimable army of gifts from which all the outposts of Japanese amity and conventionality are garrisoned.

Abolish baskets of oranges and baskets of eggs from the region accessible to coppers, and you shall subject the social existence of this country to a loss not less paralysing than that of the jacket button, without which its owner was not at liberty to construe Horace.

Oranges deftly piled up in plaited pyramid, and eggs neatly pillowed in a bed of husks, do not convey much from the donor or confer much on the recipient; but in the eyes of the Japanese they are bulwarks of that very material old hospitality which forbade friendship to be ever empty-handed, and taught at the same time that the value of a gift is measured by its intention, not by its quality.

MANY have an idea that although hens do need care in winter, when the weather is cold and water freezes in their pens, it is not at all necessary to pay any attention to them in summer. But this is a mistake under any circumstances. On the farm where hens have unlimited range, there may not be any particular attention given during the summer months. But when kept in small quarters, in town and villages, the poultry need far more attention during the warm months of summer than they can possibly need in winter. In summer, vermin abound; the pens and runs become coated over with droppings; ventilation is needed; clean, fresh water must be supplied, and wholesome food furnished in such quantities that it will not become stale and uneaten in the pens. To attend to all those things requires time and care, but without time and care what profit or success comes in any line of effort?

EGGS fall off during the very hot weather of summer in consequence of the unfavourable conditions of the season, unless these conditions are met and overcome by proper attention. This being the case, the hens are healthy and the number of eggs is kept up—two results which always follow good care. Remember, then, that the best economy of the poultry yard demands that it have daily care throughout the heated months. Fresh water given daily, a change of food, and a constant watch that an over-supply be not given at any time; fresh grass and sods placed in the yards at intervals of a few days; abundant ventilation of the pens must be given; the droppings kept cleaned up; the perches occasionally coated with a mixture of lard and sulphur; dust baths furnished, and thorough watchfulness. Toward night—say during these long days at five or six o'clock P.M.—turn the hens from their pens and give them the benefit of a leg stretching in the garden and among the grass or fruit trees. While they are enjoying this airing get a spade and dig over the earth in the pens. It will be good exercise, and the next morning the hens will think they have new quarters. Attention to these things will yield health to the hens, and a good supply of eggs for the family right through the hot weather.

ACCORDING to the agricultural statistics for 1880, the yield of wheat in Australia for the year has not proved so large as was anticipated, an increase of area from 233,368 to 252,540 acres only resulting in an increase from 3,613,266 bushels to 3,708,737 bushels.

DURING the year 1880-81, several interesting experiments were tried at the Saharunpore Botanical Gardens. Not the least interesting was one with *Taraxacum officinale*. An indent for 200lbs. of the extract having been received from Calcutta, an attempt was made to grow the plant and prepare the extract on the spot. It is satisfactory to find that the experiment was thoroughly successful. From half an acre 109lbs. were made, at the following cost:—

To cultivation, &c.	...	...	13	8	0
„ preparing extract	...	...	62	8	0
Total	...	...	76	0	0

or 11·156 annas per lb. The avarage price of the drug in England is 2*s*. 2*d*., so that when freight charges and loss by exchange are added, the cost in India will not be less than 1 rupee 8 annas per lb. From this experiment it will be seen that an acre will produce over 200lbs. of the extract, and as improved modes of preparation will no doubt be found out, the cultivation of this valuable medicine will become one of our industries.

ON the flowering of the bamboo, the same report speaks as follows:—

The present year will be a remarkable one in the history of the *Lattang bans (Bambusa arundinacea)*, which is now in flower in this district, and in Debra Doon, where it has formed magnificent clumps of over 30 years' growth. The destruction of these, which is the inevitable result after flowering, if left to themselves, will deprive Dehra for a time of one of its most beautiful features. Among the remedies which have been suggested for keeping them alive under these circumstances is one known very well to natives, and is said to have been successful. As soon as the flowers begin to appear, all the stems are cut down close to the ground, after which the roots are covered over with manure and litter and set fire to. When the rainy season comes on, it is said that an abundant crop of young shoots will break out from the old roots. It is not difficult to understand the cause of death under ordinary circumstances when we consider how the plants must be weakened by the sudden production of such an enormous mass of flowers; and at the same time, being almost devoid of leaves, the plants are thereby deprived of the means of obtaining their proper nourishment by the action of the roots. The effect of fire being applied may possibly be to seal up the points from which the remaining strength or sap of the plant was issuing, and to cause it to be stored up just as Nature does in the case of bulbs, tubers, and other fleshy underground organs, and which under suitable conditions are capable of perpetuating the plant. There will be an abundant supply of seed for sowing during the rains.

THE value of human excreta has been repeatedly brought to notice, but we almost despair of making any progress in introducing this valuable manurial agent to the notice of the Indian rayat. The only form in which they will use it, is in the form of *poudrette*. At the Cawnpore Experimental Farm a careful experiment was tried, with marvellous results. The crop grown was barley. The following were the results:—

				Manured.	Unmanured.
Grain	...	...	...	lbs. 2,851	1,842
Straw	...	...	...	„ 3,603	1,968
Value of crop	...	...	...	Rs. 66-7-1	40-12-9

The manure cost practically nothing beyond the labour of incorporating it. The cultivation in both cases was good, and if the prejudice held by the rayat against this manure were got rid of, much good would result. The example set our Municipalities by Poona and Umritsur, might be followed with advantage all over the land. Umritsur conveys the excreta, deluged with water to

large tanks where it is precipitated, but Poona goes to the root of the the matter, by changing the excreta into *poudrette*, in which form it loses all its noxious properties, and is valuable as manure.

The subject of wind-mill too has occupied the attention of the Cawnpore agricultural authorities. The results of an extensive experiment are given, but we do not by any means consider them at all satisfactory or conclusive. In all such experiments, the data on which we go must be exact, or the deductions are valueless. The Superintendent says:—"The experiments are not so satisfactory as could be wished since it was only possible to make a rough guess as to the most important factor—the velocity of the wind." It is so far satisfactory that the importance of this factor is seen and acknowledged, as in Lucknow at a recent trial of ploughs the element of draught was eliminated, as of no importance, which, from a consideration of the class of cattle owned by the rayat, we should have imagined it one of the most important factors in the experiment. It is clear to begin with, that the class of wind-mill experimented was very inferior, as with a breeze estimated at from 8 to 9 miles an hour, the horse power evolved was only ·055. It is assumed that the average speed of the wind in those provinces is 5 miles per hour, and at that rate it was found that 1,500 cubic feet of water was raised in 24 hours, at a cost including all charges, of 5 annas. Now 1,500 cubic feet will supply an inch of water, over 5 acres, so that the supply of an inch of water over an acre costs only one anna. In this country where labour is so cheap, this may not be considered of any value, but it must be remembered that most well irrigating is performed by bullocks, and in that department we are sadly behind. So far as this experiment has shown anything definite, it is in favor of the adoption of the wind-mill. To utilize this mode of drawing water, it will now even be necessary to have large *pucca* tanks placed along side each well, at such a level as shall make the last drop of water available for irrigation by gravitation. Until this is done, the wind-mill will only be of advantage when there is sufficient wind to turn it. By having large tanks of *pucca* masonry, they can be filled when there is wind, and the contents will then be available when wanted.

There is plenty of elbow-room in Texas still. The census returns for the State show that of fifty-seven counties fifteen have no population, and the others have from three only to five hundred inhabitants. These fifty-seven counties are practically uninhabited. It must be remembered, too, that this great State is habitable in almost every part, the "bad lands" being very small in proportion to the whole area, while railway enterprise is opening up a very large part of the State to immediate settlement.

We extract the following from an American paper Experiments in sowing wheat at different depths show the following results. The first column shows the depth seed was sown; second column the number of days that elapsed before the plants appeared above ground, third column, proportion of plants that came up.—

½ inch ...	... 11 days ...	... ⅞
1 inch ...	... 12 „ ...	... all
2 inches ...	... 18 „ ...	... ⅞
3 inches ...	... 20 „ ...	... ¾
4 inches ...	... 21 „ ...	... ½
5 inches ...	... 22 „ ...	... ⅜
6 inches ...	... 23 „ ...	... ⅛

From the Agricultural statistics of Great Britain for 1881 just published, we gather that the extent of land under wheat was 2,806,057 acres, or 103,381 acres less than in 1881. Barley 2,442,405 acres or 25,036 acres less than in 1880; oats 2,901,135 acres, or an increase of 104,230 acres; potatoes 579,431 acres, an increase of 28,499 acres over 1880, and hops 64,128 acres, or a decrease of 1,577 acres. During the year the live stock of the country numbered cattle 5,911,524; sheep and lamb 24,582 154; and pigs 2,048,034.

A *Standard* telegram from New York says that it is reported from North Carolina and Virginia that the cotton crop is three per cent. below that of last year. Charleston reports say that out of fifty-three replies to a circular addressed to cotton-growers in South Carolina forty-five are unfavourable. Over sixty replies from Alabama are of an undecided character, while those from Mississippi range from fair to good. As to those from North Mississippi, North Arkansas, and West Tennessee, out of eighty-two replies twenty-five are good, nineteen moderately good, thirty-eight poor. New Orleans reports that out of over a hundred replies from cotton-growers in Louisiana the majority state that the crop is not nearly so good or promising as that of last year. It would seem, then, from the bulk of the reports, that previous estimates of the crop were too sanguine. Drought is generally complained of, but much depends on the picking. We wonder whether this means better prices of India cotton. Possibly it does, and we are encouraged to hope that the ryots may be able to meet the deficiency as the weekly reports for the Central Provinces and other cotton-growing districts continue very favourable.

The following paragraphs give us a fair idea of what Railway enterprise is doing in America and at home :—

During the first two weeks of July last the Eastbound grain shipments from Chicago averaged 670,000 bushels daily. While that moved by the railway averaged 339,015 tons per day.

The gross earnings of all the railways working in America for the year ending 31st December 1880, was Rs. 1,23,08,03,862, while the net earnings were Rs. 51,03,86,872.

The London and North-Western Railway carry on an average 50,000,000 passengers annually, and between 30,000,000 and 40,000,000 tons of merchandise, while the earnings amount to Rs. 20,00,000 per week.

When will our railways ever move 339,015 tons of grain per day? As we have often pointed out, the American railways have reduced their grain-carrying rates to the lowest possible paying point, and they are getting their reward. With the solitary and honorable exception of the East Indian line, our system is to choke a rising trade by increased charges, a notable example of this being the Great India Peninsula line whose earnings, we observe, have fallen to Rs. 285-14-4 per week per mile.

The *Colonies and India* remarks that the following return of sheep held by "squatters" taken from the *Government Gazette* for Canterbury and Otago, New Zealand—gives an idea of the vast flocks owned by single individuals in the Australasian colonies:—New Zealand and Australian Land Company 300,000 sheep; Mr. Robert Campbell, 386,000 sheep; Mr. George Henry Moore, 90,000 sheep, Messrs. Dalgetty & Co., 208,000 sheep; Messrs. Clifford and Weld 80,000 sheep; Sir Dillon Bell 82,000 sheep; Hon. William Robinson, 68,020 sheep; Sir Cracroft Wilson, 48,000 sheep; Mr. Kitchen, 80,000 sheep; Mr. Allan M'Lean, 500,000 sheep.

A planter writes:—"Can you give me any information about the Chinese tallow tree; *i e*, its value or the price the seeds fetch in the home market?" From the *Treasury of Botany* we take :—

"Stillingia.—The tallow-tree of China is the best known representative of this genus of *Euphorbiaceæ*; but there are two or three other Chinese and Japanese species, and as many more natives of the Southern States of America. With the exception of the tallow-tree and one herbaceous species, they are shrubs; and all have alternate entire leaves and terminal catkin-like spikes of flowers. The fruit is a capsule composed of three one-seeded opening pieces, and is girded at the base by an enlarged bracket. *S. sebifera* the tallow-tree, is a native of China and the adjacent islands, but it has been introduced into and partly naturalised in India and the warm parts of America. It has rhomboid-shaped sharply taper-pointed leaves about two inches broad, on slender stalks with two prominent glands at the point of attachment between the stalk and leaf; and its flowers catkins are from two to four inches long. Its fruits are about half inch in diameter, and contain three seeds thickly coated with a fatty substance which yields the tallow. This is obtained by steaming the seeds in large cauldrons, then bruising them sufficiently to loosen the fact without breaking the seeds, which are removed by sifting; and the fat is afterwards made into flat circular cakes and pressed in a wedgepress, when the pure tallow exudes in a liquid state, and soon hardens into a white brittle mass. This tallow is very extensively used for candle-making in China; but as they get soft in hot weather, the candles generally receive a coating of insect

wax. A liquid oil is obtained from the seeds by pressing. The tree yields a hard wood, used by the Chinese for printing blocks, and its leaves are employed for dyeing black."

A MAN, by name of Tanaka Tsurukichi, living in Tsukudacho, Fukagawa, Tokio, has been paying the utmost attention to salt manufacture for a long time past. He has visited every reputed salt-producing district throughout the Empire since the era of Keio (1865-67), and in 1872 he went to America, where he diligently inspected similar establishments. After his return he again undertook a journey through Japan in order to discover a place where the American methods of manufacture could be adopted. At last he fixed upon the Ogasawara (Bonin) islands as a suitable site to carry out his enterprise. Therefore, a short time ago, he went thither with a Tokio merchant, Kinoshita Junnosuke, who has made several visits to the islands. After due trial he obtained a result not inferior to that averaged in America. Having lately obtained from the Tokio Fucho permission to establish salt works in Ogasawara, he is said to be about to go there on the 5th proximo. If the Nichi Nichi adds, the manufacture is successful, a great benefit will be bestowed on the people in their daily consumption.

SPEAKING of a proposed utilisation of the water power of the Punjab Canals, the *Civil and Military Gazette* says: "In the case of the Egerton Mills, a prominent characteristic of the undertaking is the utilization of the mechanical power which is supplied to India in the descent of the water brought by the monsoon to the Himalayan ranges; a power which, under the developments of modern science now so rapidly progressing in this direction, may be expected to afford a motive force to machinery which will go far to compensate for the absence of coal and other fuel in the upper regions of the continent of India. The Egerton Mills will be worked by a turbine set in the channel leading out of the Baree Doal Canal. The stream conducted through this channel will—after performing its duty of providing motive power to the machinery, be returned to the canal and utilized for its original purpose—namely, irrigation. We are glad to know that the co-operation of the Punjab Government in affording liberal terms for the utilization of waterfalls on the Punjab canals has given an important impetus to the establishment of this undertaking, which will no doubt be followed by others of similar character in North India, wherever this economical supply of motive force is attainable." The amount of power available from the flow of canals on the plains may be comparatively trifling, but there is sufficient fall in the "lay of the land" on the canals under the Himalayan and Sub-Himalayan ranges, to produce a large amount of motive power. For instance, in the Doon Canals, the fall southward from the Himalayas is about one foot in 100. At every three hundred yards there is a fall from 6 to 9 feet, and as a large body of water falls this distance, it follows that a large power is developed, which is but partially utilised by a wretched flour mill here and there. The bulk of water is about 2 to 4 superficial feet of cross section, and if it were carried on the level and allowed to fall 16 to 20 feet, it would develope 30 horse-power if utilised in working a turbine wheel.

SIR GEORGE COUPER'S resolution on the irrigation report of the North-Western Province and Oudh for the *rabi* season of 1880-81 is before us, and it confirms the opinion that the rate as at present fixed is much too high, and that the only way to reduce it and to make the canals and other irrigation works more popular and useful, is to make the rate a compulsory one, payable on all lands irrigable by the canals. The following are the statistics of acres irrigated, and assessments for the *rabi* seasons of the last four financial years:—

		Acres.	Assessment. Rs.		Assessment. per acre.
1877-78	...	729,845	15,23,990	...	Rs. 2 1 2
1878-79	...	1,075,952	21,75,715	...	„ 2 0 5
1879-80	...	844,330	16,51,524	...	„ 1 15 3
1880-81	...	1,032,010	21,09,061	...	„ 2 0 8

Here then we have a charge of two rupees per acre for one-half of the year—the dry half, it is true. But we may nevertheless safely assume three and-a-half rupees as the annual charge per acre. This sum capitalised at three and-a-half per cent.—for if the Oudh and Rohilkund Railway Company can borrow at this rate, surely the Government of India can—represents a capital cost of Rs. 100 per acre. Now a fourth part of this sum spent on wells would place the cultivator practically beyond the fear of drought, and make famine impossible. It may be said that these canals are capable of irrigating a much larger surface than these figures represent. This is very true, but while payment for water used only follows the use of water, so long will the cultivators refuse to use water until spurred by the fear of famine. With a compulsory assessment at perhaps one-third the above rate, all would use it, and the income of the irrigation would cease to depend on the rainfall.

OUR railway contemporary of Allahabad tells us that "In 1879 wheat was carried from Buffalo to New York, 450 miles for one anna three pie, and corn for one anna and one pie a bushel, the lowest it had ever touched. At the same time steamers on the Upper Lakes were carrying wheat the long detour from Chicago to Buffalo, 1,000 miles, for eight pies per bushel, and corn was carried for less." That is to say, the carriage of wheat was at the rate of ·14*d.*, and of corn at ·135*d.* per ton per mile. Wheat carried 1,000 miles for eight pies per bushel is at the rate of ·037*d.* per ton per mile—and yet we are asked why does not India engage more largely in the wheat trade to England. A comparison of these rates with those prevailing in India will form a sufficient answer to the question.

THE duplicity which attends all diplomatic action is a very disgraceful feature in our political systems. The latest instance in which this is illustrated is in a letter to the Society for the Suppression of the Opium Trade, a society, the members of which are doubtless actuated by worthy motives, however little these may be directed with discretion. The letter is written by no less an official than the Grand Secretary to the Emperor of China. He says: "Opium is a subject in the discussion of which England and China can never meet on common ground. China views the whole question from a moral standpoint; England from a fiscal. England would retain a source of revenue in India, while China contends for the lives and prosperity of her people. The ruling motive with China is to repress opium by heavy taxation everywhere, whereas with England the manifest object is to make opium cheaper, and thus increase and stimulate the demand in China. With motives and principles so radically opposite, it is not surprising that the discussion commenced at Chefoo in 1876, has up to the present time been fruitless of good results. The whole record of this discussion shows that inducement and persuasion have been used in behalf of England to prevent any additional taxation of opium in China, and objections made to China exercising her undoubted right to regulate her own taxes—at least, with regard to opium. I may take the opportunity to assert here, once for all, that the single aim of my Government, in taxing opium will be in the future, as it has been in the past, to repress the traffic—never the desire to gain revenue from such a source. Having failed to kill a serpent who would be so rash as to nurse it in his bosom? If it be thought that China countenances the import for the revenue it brings, it should be known that Government will gladly cut off all such revenue in order to stop the import of opium. My Sovereign has never desired his empire to thrive upon the lives or infirmities of his subjects. My Government is impressed with the necessity of making strenuous efforts to control this flood of opium before it overwhelms the whole country. The new treaty with the United States, containing the prohibitory clause against opium, encourages the belief that the broad principles of justice and feelings of humanity, will prevail in future relations between China and Western nations. My Government will take effective measures to enforce the laws against the cultivation of the poppy in China, and otherwise check the use of opium; and I earnestly hope that your society and all right minded men of your country will support the efforts China is now making to escape from the thraldom of opium." This plausible gentleman does not say a word about the steady efforts which are being made to extend the cultivation of the poppy in China, in order that the Chinese Government, and not the Indian may get the benefit of the duty.

The Chinese are evidently arousing themselves. They have, like Rip Van Winkle, been asleep for an indefinite period, but are at last showing signs of returning animation. China must at one time have been a progressive nation, as is evidenced by the state of its civilisation and general advancement, in an age when Western Europe was very far behind in the race of progress. But for many centuries China has stood still, and so conservative has she been, that only a very few years ago her Government purchased a railway which a few sanguine individuals had contrived to construct, for the express purpose of pulling it all up. Within the last twelve months, however, rumours of the dawn of an era of activity are not wanting. The latest phase of this is a desire on the part of the Chinese to develope the vast resources of a mineral nature which are known to exist in their country. On this subject a home journal says:—

The Chinese authorities are making strenuous efforts to develope the vast mineral resources known to exist in the country to the west and north of Tientsin. The district of Chihli is said to be eminently a country of minerals, and as a result of mining operatoins that have recently been carried out, enormous beds of coal of old formation have been found, mostly between limestone layers. Then in the same districts are almost inexhaustible beds of ironstone, and iron ores of the better kind, such as spathose, limonite, hematite, have also been discovered in rich deposits. At no great distance from the chief coal mines, copper ore of abnormal richness has been met with; and in the hills which bound the vast coal and iron district, lead, silver, and manganese await the miner's advent. If the country is half as rich in mineral resource as the amount we have summarised indicates, then there is a magnificent field opening up for the exercise of Celestial enterprise. It is anticipated that the first produce of the coal mines will be brought to and sold in the Tientsin markets before the close of the present summer.

This desire to keep up in the race with other countries, has for a considerable time been seen among her mercantile classes, who are known to be shrewd, clever, business men. All along the coast of China, there are fine steamers running, carrying on the vast trade which is necessary for such a large population, and many of the best of those lines are owned by Chinese. We learn that a movement is at present on foot in Rangoon, where many Chinese merchants have their places of business, to establish a line of steamers between that port and Singapore, and it behoves the mercantile community of San Francisco to see to the efficiency of their oceanic mail service, or some day the "Heathen Chinee" may prove a powerful competitor.

There are in Great Britain 23,000 females who are farming. These women enjoy all the rights and privileges of men with one exception, they cannot vote for members of Parliament, but they can vote on all municipal questions. It is very seldom, however, that they exercise this privilege.

The Census Bureau furnishes the following statement, giving the result of the first count of the cereal crops of 1879 80 in comparison with that of 1869-70 :—

	Acres.	Bush. 1880.	Bush. 1870.
Buckwheat	851,304,	11,851,738	9,820,721
Barley	2,005,466	44,149,479	29,761,305
Oats	16,150,612	507,970,712	282,107,257
Wheat	35,487,061	459,501,093	287,745,626
Indian corn	62,326,852	1,773,106,576	760,944,546
Rye	1.845,321	19,863,632	16,918,795
Total	118,661,619	2,716,243,230	1,387,299,153

The sugar beet is a native of the shores of the Mediterranean where it grows wild without the aid of cultivation.

The first wheat of the 1881 crop, was received at St. Louis on the 9th July from Fort Worth Texas, consigned by Brooks and Myles of that place, and was sold at auction at the fancy prize of §1 50 per bushel. The first wheat of the 1880 crop reached at St. Louis, May 29th, eleven days earlier than this year, and also came from Fort Worth.

The Scinde, Punjab and Delhi Railway seems to have passed the turning point, and is now on the way to success. For a very long time the working expenses of this line made a dividend quite out of the question. The following table will illustrate this :—

			Working expense %
Average of 4 half-years ending ...	Dec.	1873	83·06
Average of 4 half-years ending ...	June	1874	75·65
Average of 4 half-years ending ...	Dec.	1877	68 42
Average of 4 half-years ending ...	June	1868	60·94
Half-year ending 31	Dec.	1878	66·64
Half-year ending 30th	June	1879	68 25
" 31st	Dec.	1879	57·23
" 30th	June	1880	53·44
" 31st	Dec.	1880	58·72

The three latter half-years show some improvement. For comparison, we may state that the percentage of working expenses in the East Indian line for the half-year ending 30th June 1880 was only 32 51. We understand that the coal question has a good deal to do with this, the coal on the S., P. and D. line costing Rs. 22·9 per ton, while on the E. I. R. the cost is only Rs. 6·4. The statistics in the report for the half-year ending December 1880, are here and there a little hazy; for instance, we are gravely told that "on the intermediate class there has been a decrease of 80·1 per cent. in numbers, and of 223 1 per cent. in value." We are under the impression that a decrease of 100 per cent. would be quite sufficient to obliterate the traffic altogether, and we cannot quite understand how anything can possibly decrease by 223·1 per cent.

Certain experiments recently made by Professor Tyndall, upon the use of sulphuric acid in promoting the more rapid germination of seeds, or rather fruits, contained in shelly capsules, such as nuts, almonds, and stones have been attended with such marvellous results that attention may well be directed to it in India, where the difficulty of raising fruit trees from imported stones with a view of improving stock, has been the frequency of mildew setting in before germination takes place. Seeds and stones soaked in a solution of the acid receive such a germinating impetus from this tonic that they shoot in a space of time hitherto unknown to agriculturists. This should be good news to those residents of our hill stations who have failed hitherto in raising plants from English or Australian stock: many seeds of aquatics, such as water lilies, have been known to remain dormant for two years, sorely trying the patience of those enthusiasts who have essayed their growth.

A very rapid cure of the foot-and-mouth disease in cattle is said to have been discovered by the Duke of Brunswick. He uses a solution of salicylic acid, prepared by pouring some hot water on about three tablespoonfuls of the acid in an earthen vessel, adding lukewarm water to make up a gallon. The mouth and feet of the diseased animal should be carefully washed three times a day with this liquid, and the tops of the hoops well powdered with the dry acid after each washing. To the drinking-water should be added two tablespoonful of the acid dissolved in hot water.

Experiments which have been made for some time past at the Saharanpore Botanical Gardens with Austrian meadow grasses have proved their inferiority on the whole to the Indian *dup* grass.

According to the last municipal report, there are five sewage farms in Madras, but three of these are of importance. The object of establishing these sewage farms by the Municipality is not so much to make a profit as to dispose of the sewage "which has as yet shown no bad effect on those residing near the places of disposal." The working of DeMellow's road farm last year resulted in a profit of Rs. 46 11-5—the sale of grass and hay amounted in the year to Rs. 2,468-2-1. The Triplicane farm brought in Rs. 2,200 by the sale of hay and grass, but the expenses were Rs. 2,791-10 5. The Kistnampet farm was worked at a profit of Rs. 479-14-5. The Egmore farm was worked at a loss of Rs. 885. The failure of the crops of grass in some of the farms is attributable to insects having attacked the crops after the heavy rains of last year.

The following comparative statement of the foreign wheat crop is from French statistics just published :—

		Bush. 1879.	Bush. 1880.
France	... ...	216,000,000	240,000,000
Russia	... ...	180,000,000	160,000,000

Total ...	...	877,500,000	1,041,000,000

THE culture of bees in Northern Italy has given rise to an industry which appears likely to increase in importance, namely, the supply of queen bees and swarms to various countries in Europe and America. The queen bees travel in wooden boxes, accompanied by 200 working bees. The boxes have four slits for air. Inside are two small frames, one containing a full, the other an empty honeycomb. They vary in size according to the distance they are sent. The Italian bees have the reputation of being more docile and productive than any other kind of bees, and it is to this that they owe their value.

A GERMAN statistician has arrived at the conclusion that the following is an approximately correct statement of the population of the world :—

Europe	... ...	315,929 000
Asia ...	... ...	834,707,000
America...	... ...	95,405 000
Africa ...	... ...	205,679,000
Australia, &c.	... ...	4,121,000
Polar Regions	... ...	82,000
	Total	1,455,923,000

The extremes of density and sparseness of population are China and the Polar regions, of which the details are as follow :—

	Square miles.	Population.	Population per Sq. miles.
China	7,383,750	434,630,000	58·86
Polar Regions	2,411,875	82,000	·031

There are no doubt more densely populated regions than China, but it must be remembered that the above statement includes much land that is not populated at all.

IN agriculture, giant growth is due to giant culture.

MEXIA, Texas, with only 1,250 inhabitants shipped over 20,000 bales of the cotton crop of 1880.

THE wool clip of Coleman county, Texas, for 1881, is set down at 150,000 pounds. Prices from 21 to 21 cents. per pound.

THE total area of lands available for wheat culture in the United States is not less than 470,000,000 acres. Our entire wheat crop of the past year would not supply seeds enough to sow so vast an area of wheat land.

THE average of corn per acre in 1879 in Vermont as given in the report of the Department of Agriculture, was 30 bushels. The lowest average was in North Carolina, 7 bushels ; the highest in Nebraska, 41 bushels.

THE following is from a Mercara correspondent :—The steadiness and attention which this product is meeting in this country, augurs well for its future success ; and the day is not far distant, when there will be large supplies of a rich bark, holding its own in London, against that sent from other parts of the world ; for in the course of two or three years at the most, there will be many acres of cinchona trees of sufficient growth to be stripped or barked.

IN accordance with a suggestion of Colonel Beddome, the Government have sanctioned the expenditure of a sum not exceeding Rs. 1,000 for the experimental trial of various patent manures. It is understood that valuable artificial manure can be obtained from the firms on the West Coast, Mr. W. Rowson, Assistant Superintendent, Government Chincona Plantations, Neddiwuttum, having proposed "that our soils be sent home for analysis, and that suitable patent manure be procured from England." The Government have replied that no analysis of the soils need be made at present.

THE *Mainichi* remarks :—Two gentlemen of Sanuki province by name Miyatake and Mukoyama, have established a sugar factory on a western model at Shido-mura, the Samukawa district ; and after several trials white sugar has been successfully made. Specimens have been forwarded for examination to the Agricultural and Commercial Department, which after careful comparison with foreign articles has found it to be not inferior to the imported staples. It is said that the Minister intends to present some home made sugar to the Imperial Household shortly.

OFFICIAL PAPER.

OPIUM IN TREATY PORTS.

To the Chairman, Chamber of Commerce, Calcutta. Pakhoi, China, 31st July 1881.

SIR,—As we find the Chinese authorities, under one pretext and another, are establishing more and more offices for the collection of new taxes on Indian opium in the Treaty Ports of Pakhoi and Hoihow in the Province of Kwang Tung, to the great detriment of trade in this article, and as one of these new offices, called the *Haitang* (Defence Tax), has lately interfered with our legitimate business as regards opium by molesting our customers, and even forcibly seizing our own opium from our own people, we have complained to her Majesty's Consuls both at Pakhoi and Hoihow, who have referred the whole question to her Majesty's Minister at Peking.

Considering this question to be one which not only affects ourselves, but which may also have a good deal of influence on trade in Indian opium generally, and as such may interest your Chamber, we avail ourselves of this opportunity to state as briefly as possible what has transpired.

We take our stand point on the following ground, *viz.* :—Clause 1, Rule 5, section 3, Articles of trade with China, Tientsin Treaty, 1858, says—"Opium will henceforth pay 30 taels per picul import duty, The importer will sell it only at the port. It will be carried into the interior by Chinese only, and only as Chinese property."

It has been urged by the Chinese authorities that it was contemplated by the framers of the Chefoo Convention, that a change should be made, and that the *Lo kin* (war tax,) should be paid by the purchaser. It is, however, this very clause which has not been agreed to by Her Majesty's Government, and as the Chefoo Convention is not ratified, it cannot be brought forward either in support of or against the action of the Chinese authorities.

The clause of the Tientsin Treaty above referred to is all we have to go by at present, and we submit that, in accordance with that clause, no tax whatever beyond the import tariff duty of 30 taels per picul (say Rs. 115 per chest, about) can legally be levied within the limits of the Treaty Ports on foreign opium imported by a foreign vessel from a foreign country.

As foreign merchants our limit in which to transact business in opium, that is to *buy* or *sell* the article, is clearly defined as being restricted to the Treaty Ports. The clause permitting us to *sell* in the open port must reasonably permit purchasers to *buy* from us without molestation. If this is not the case the portion of the clause permitting us to sell appears to us to be nugatory.

As matters now stand, however, although we have no doubt the Chinese authorities are well aware that they have no legal right to levy arbitrary duties within the limits of the Treaty Ports, either on Indian opium or on any other foreign goods within the limits of the Treaty Ports, yet with their well-known propensity for trying how far they can go with impunity, they have commenced first by establishing the *Lo kin* (war tax) office in the ports and imposing a tax of 23 taels per picul (say about Rs. 90 per chest). At the close of 1879 the *Haitang* office was opened and 22 taels (say Rs. 69) per chest demanded ; this was opposed by native merchants, who appealed to foreign merchants for assistance, and so far as British merchants at this port were concerned H. M.'s Consul, in reply to a communication from the Prefect, clearly expressed his views that in accordance with the Treaty no other tax beyond the 30 taels per picul could be levied in the port on Indian opium imported by foreign vessels from a foreign country. This principle was admitted by the Prefect, and for some time the business of British merchants was not interfered with directly, but the office was not removed.

In January last, the officials finding that they had gone along so far without being obliged to close their establishments in the ports, imposed another tax called *Kau li* (a tax on prepared opium) taels 30,200 (say about 94 rupees) per chest. The actual collection of this tax commenced about May last, and for their own convenience, they made it payable on raw opium, in the same way as the other imposition.

They now contemplate levying an additional tax of 150 taels (say Rs. 506) per chest, also to be collected in the open port. So that duties will then total in round figures as follows :—

Import Tariff duty per chest	Rs.	115
Lokin tax	"	90
Haitang	"	69
Kauli Tax	"	94
New tax proposed	"	506
Say total per chest rupees		874

of which we contend that only the equivalent of Rs. 115 per chest is legally leviable in the port.

The Chinese authorities are evidently of opinion that the time has now come for them to make a bold effort to over-ride altogether the article of the Tientsin Treaty above referred to, and no doubt with this object the *Haifang* office has lately placed soldiers around our premises, seized our customers just outside our door, and crowned their actions by seizing and maltreating one of our own men close to our house and forcibly taking from him our own opium which he was carrying along. We had paid the legal tariff duty on this opium and it had not changed hands. The same things have been done at Hoihow.

Both at Pakhoi and Hoihow her Majesty's Consul demanded the immediate restitution of our property, but the *Haifang* office persistently refused to give it up. That office, the *Haifang*, we may here explain is carried on by a company of Chinese merchant, principally from Hong-Kong who hold no official position and to whom the Viceroy of Canton has farmed the privilege of collecting the *Haifang* and *kanli* taxes for the sum of taels 90,000, say Rs 3,03,750 per month, their area being the province of Kwangtung.

The Prefect of this port although in reply to the representation of H. M.'s Consul, he again admitted the principle for which we contend, dared not compel the restitution of the opium as the *Haifang* office immediately appealed to the Viceroy of Canton to whom the Prefect is responsible for his action. The Viceroy, in reply to H. M.'s Consul, said that he would cause inquiries to be made as to whether the opium seized had passed out of foreign possession or not, but we are in possession of proofs that at the same time he privately instructed the Prefect not to return the opium.

The Viceroy further stated to H. M.'s Consul that while opium in foreign possession could not be taxed beyond the tariff duty yet the moment it passed into Chinese hands, '*no matter whether in the Treaty port or not*, it could be taxed in any way the Chinese authorities might please.

A copy of a document has come into our possession, which clearly shows that the *Ts'ung Li Yamen* (Board of Foreign Affairs) at Peking, will, if possible, support the Viceroy.

If the principle which the Viceroy contends for be admitted, then the right granted to importers under the Treaty of Tientsin, to the whole area of the Treaty Ports, in which to transact business, is at once done away with, and each individual merchant will be limited to his own individual premises, because the moment opium passes his door, it will be seized. And should the Chinese officials succeed in their present attempts, legitimate business in Indian opium at the Treaty Ports will no longer be possible either for foreign or native merchants. Smuggling will no doubt be carried on to some extent, but Indian produce in this direction must eventually give way to the native article Yunnan.

Lately there has been a greater demand for Indian opium in China, but this is explained by the fact that native merchants are anxious to import prior to the imposition of the new tax.

The well meaning people connected with the Anti-Opium League may perhaps be of opinion that the imposition of these almost prohibitive duties shows the desire of the Chinese Government to put a stop to the traffic. This, however, is certainly not the case.

Prior to the signing of the Treaty of Tientsin, the whole system of taxation (barring salt and land) was on transit, and arbitrary, being collected by insufficiently paid officials in the provinces, who were dependent on what they could decently stop out of their receipts, and who besides had a lively notion of the taxableness of foreigners. The revenue had to filter through their hands, and somehow before reaching Peking had enabled the officials (salaried at ridiculous rates, which would not pay one of the several secretaries necessary in their Yamen) to acquire wealth.

The framers of the Treaty of Tientsin were well aware of this, and it was precisely this system which they intended to alter. By the provisions of that treaty duties were thenceforward to be collected according to the prescribed tariff, and the result without deduction was to be sent to Peking.

The Peking Government, though now in receipt of a large and certain revenue (which is collected and remitted through the Foreign Inspectorate of Customs) instead of the quota which formerly reached it, has made no change in the salaries of its provincial officers, who have still to keep up the same establishments, make the same presents, and remit the same quota of revenue to the Peking Government as before, and still manage to retire wealthy after their term of office has expired. To enable them to do this, it is very plain that new sources of revenue must be found, and Indian opium is one of the articles fixed on as convenient to tax, more especially if it can be done in the Treaty Ports.

When a new tax is instituted, the right of collecting it is farmed to whoever will give the highest price. The farmers, who go into the business purely on speculation, come along armed with a proclamation from the Viceroy, and proceeded straightway to make as much money as they can. They have no regard for the Treaty, or for the morality or immorality of the trade, or for anything else but their own pockets—and it is scarcely necessary to point out what must be the result under such a system; matters will in fact soon become worse than they were before the Treaty of Tientsin were signed.

We contend that the meaning of the Treaty of Tientsin is very clear, *viz., that all goods of foreign origin, opium included*, from a foreign port by a foreign vessel shall be imported unto and sold in the Treaty Ports of China, on payment of tariff duty *only*. And it is only when such goods *leave* the port for the interior, that they become subject to other regulations. The transit regulations are intended to provide for the introduction of piece-goods, cotton, yarn, &c., &c., into the interior (though the transit pass for such goods in the provinces of Kwangtung and Kwangse, is at present practically useless, in consequence of the officials persisting in imposing differential duties on certificated goods and doing their utmost to throttle any attempt to convey the same to or from the interior. This affects Indian trade very materially, because if foreign goods could be conveyed into the interior on payment of half the import tariff duty as provided for by the Tientsin Treaty, the consumption of Indian cotton yarns, &c., would increase enormously. As concerns opium, foreigners have by Treaty given up all control of the article as soon as it leaves the port *but not before*, and this fact, combined with the circumstance that it was necessary to make a special clause in the Chefoo convention when it was contemplated that the purchaser of opium should pay *lakin*, shows that under the Treaty of Tientsin he the purchaser is *not* obliged to pay *lakin* or any other tax beyond the import tariff duty, in the Treaty Port.

In conclusion, we are glad to say that we have met with warm support from Mr. Consul Ford of Pakhoi and Mr. Consul Johnson of Hoihow, and we hope that her Majesty's Minister at Peking may decide the question at issue in a manner favourable to foreign trade.

The reluctance with which Chinese officials in this direction carry out any of their Treaty obligations, and their evident desire to utterly ignore the Treaty on all possible occasions, in which it is but too much to be feared that they are supported either directly or indirectly by the Central Government at Peking, tends to show that any concession made to them at present would be most disastrous not only to trade in Indian opium, but to the advancement of business generally at the Treaty Ports. In representing this matter to your influential body we shall be glad (should our views meet with your approval) if you will support us. If necessary we shall have pleasure in furnishing you with further particulars.

We have the honour to be, Sir, your obedient servants,

HERTON & CO.

SELECTIONS.

THE PERSIAN WHEEL.

THERE has always been a certain class of persons in this country of opinion that canal water for irrigating purposes should be invariably delivered below the surface of the ground, so that it should not be allowed to flow away wastefully in excess of requirements; but, as it would always cost money to lift it, it would only be used when required. Also, it was assumed that canals so constructed would lose less water by percolation, and would consequently tend less to raise the spring level and so swamp the country, than if they were constructed in embankment.

Paradoxical though it may appear, experiment shows that a canal in embankment loses less by percolation than one in cutting, and therefore tends less to raise the spring near it, probably because the soil near the surface is less porous than what is reached by digging a few feet down. Luckily for the country, the advocates of this low-level canal system were overruled, and our perennial canals deliver most of their supply by flow. It is interesting, however, to consider what extra expense would be thrown on the cultivators if all the water for irrigation had to be raised. Take, for example, that Bari Doab Canal, which delivers about 2,500 cubic feet of water per second, on an average, through the year. All canal water which is lifted in this canal is lifted by means of a modification of the Persian wheel, altered in certain respects to suit a low lift, and known as a *jhallar*. A *jhallar* worked day and night requires four pairs of bullocks, costing Rs. 60 per month to keep, and is capable of lifting about one-sixth of a cubic foot per second, so that, to lift all the water supplied by the canal 15,000 *jhallars* would be required, and the monthly charge for bullocks would amount to nine lakhs of rupees, or per annum, Rs. 1,08,00,000 paid on one canal for raising water, which might have been delivered on the surface. As it is, about a tenth of the water has to be raised, so that the annual sum paid for bullocks for raising water on the Bari Doab Canal, may be taken at about 10 lakhs per annum. This water is probably raised on an average five feet, in some cases, the water being only just below the surface, but scarcely ever more than 10 feet below, as it would not pay to dig a watercourse deeper than this, even if water were granted for such high land. A *jhallar* from its construction must always raise water three feet above the watercourse in which it is to flow away, the top earthen vessel or *tind* being two feet above the trough, and the trough at its high end a foot above the bed of the watercourse; consequently, in order eventually to raise the water five feet, it is necessary to raise it eight feet and drop it three. Now, this loss of 37½ per cent. of the work is extra to such unavoidable losses as friction, evaporation, leakage, &c., which, no doubt in such a primitive machine, amount to as much again; and it might be nearly all got rid of by the adoption of a more economical motor. The case quoted is taken as the probable *average* for the whole canal; but in cases where water has to be lifted only one foot, *jhallars* may be seen at work in many places raising the water four feet and dropping it three, and so wasting 75 per cent. of the bullock's power, and costing their owners Rs. 45 per month uselessly. Here is a field for the Punjab Agricultural Department.

These latter remarks do not apply to the whole of the country, or even to the whole of the Punjab; for the method of raising water a few feet by means of a basket swung by two men, and which is universally adopted on the Western Jumna Canal, is probably one of the most economical methods which could be devised. But this will not do for the zemindar

of the Northern Punjab; he must have a method of utilising bullocks, not coolies, the latter being too expensive, too scarce, and too idle.

The Sirhind Canal will in a few years be distributing 5,000 cubic feet of water per second over about a million acres of land, and there is no reason for doubting that twenty lakhs of rupees will be wasted annually in like manner in raising its water.

Let us consider the figures in another way. A *jhallar* in which a pair of bullocks are yoked lifts one-sixth of a cubic foot of water per second, five feet, that is, the work done per second is $\frac{62\frac{1}{2}\times5\times60}{6}=3{,}125$ foot lbs. of work per minute. Let us compare this with the supposed efficiency of various animals taking the figures from "Molesworth's Pocket Book." Mr. Molesworth gives the work obtainable in foot lbs. per minute from a horse as 21,000 ft. lbs.; *one* ox 12,000 ft. lbs; an ass 3,500 ft lbs.; man rowing 4,000 ft. lbs.; a man on a treadmill 3,100 ft. lbs. per minute. At last we have arrived at our figure. A pair of oxen do just the same amount of work on a Punjab Canal as a convict on a treadmill.—*Civil and Military Gazette.*

DECCAN AGRICULTURISTS' RELIEF ACT.

THE proposed amendments of this Act have elicited from Mr. Justice West of the Bombay High Court, some severe criticisms on the practical working of the measure.:—

The Act, which it is proposed to amend, has now been in operation for a year and-a-half. There has been time to judge, in some respects at any rate, how far its results correspond to the sanguine expectations with which it was launched. "The problem before us," it was said "is how to keep the money-lender in his place to encourage and support him in all useful functions, . . . We must foster due credits.

We must hold the ryot responsible in our courts for what he has really borrowed, not for what he has not; and make him repay by his own exertions all that he reasonably can repay, not set him free by sudden, one-sided or heroic remedies to enter on a fresh career of indebtedness." Now, unless the general opinion is wholly mistaken, the most conspicuous consequence of the Act has been to oust the money-lender from his place by means of a one-sided remedy which has extinguished credit in making the ryot irresponsible. The whole class of those who furnished capital to the cultivator have, with a very few exceptions, closed their business, and except when retained by the hope of recovering some portion of the money due to them or by imprisonment at the suit of their own creditors, they intend to leave the districts. Where the money-lenders have bought land or lent on mortgage, an early retreat is impossible; but their former function is no longer performed. As regards the ordinary ryot, the Act, by which it was said, "We must foster due credit," has simply extinguished it. The pressure of this annihilation of credit is as yet hardly felt. The harvest of last year was unusually abundant, and the ryots, not frittering away their fortunes in paying their debts, are revelling for one year in a fool's paradise. A single bad season will bring them to ruin, and even without a bad season their funds will, in three or four years, have been as much consumed in waste as if they had paid their debts. The difference will be that the creditors having been in many instances impoverished, and having in all cases become distrustful, the ryots will be without any resource to tide them over the first time of adversity.

The principle having been formulated that "we must hold the ryot responsible in our courts for what he has really borrowed," effect was given to it by inviting every agriculturist debtor to deny his creditor's claim. The duty was imposed on the court of "going behind the bond of searching amongst by-gone transactions of years ago, evidence of which would for the most part not be forthcoming for any excuse that might be made for repudiation. The Subordinate Judges understand, as no one could fail to understand, the purpose of such provisions, and what they are expected to do under them. They cannot but be in some measure demoralized by the lop-sided equity which they are commanded to exercise. The debtor himself is directly and pressingly invited to dishonesty. He may gain, but cannot lose by a lying story. An honest admission of his debt is not received. The appreciation of the remote and obscure facts is assigned to a class of Subordinate Judges, imbued generally with the prejudices of an impecunious class, with promotion to earn, and with everything urging them to demonstrate the usefulness of the Act, the wisdom of the Government, and their own efficiency, by rejecting or cutting down the claims of the money-lenders.

Mr. West has a good deal to say also of the conciliation provisions, which do not find much favour with him.

The most interesting part of the Act is that which relates to conciliation. It rests on a highly beneficial principle, but the machinery is essentially defective. The tribunals of conciliation which were, I believe, first employed in Holland were thence borrowed by France, Denmark, and other countries, and in all they have, to the whole worked well. But in all the central idea of conciliation has been maintained and the functions of the conciliators have been restricted to simple cases with which they were competent to deal. No evidence is taken by a conciliator on the Continent. He may look at the simple documents which only can be produced in the cases brought before him; but true to his purpose he hears only the parties in presence of each other and tries to bring them to an agreement. He may put considerable pressure on the creditor by forcing him to attend again and again before granting a certificate, and he thus constrains him in many instances to make a large abatement of his claim. This the conciliators under the Act also can do. A remedy against any unfairness is to be found in a limitation of the proceedings before the conciliator to two appearances and a short interval between the two. The general result, however, of the conciliation system has, so far as I can learn, been all in favour of the creditor who knew how to use it. It has been described by a native newspaper as "like putting a knife into the hands of a butcher." This is no doubt an extravagant comparison, but it is obvious that a *sowkar*, having a friend for a conciliator and debtors as helpless as the ryots are assumed to be, may readily turn all the defences raised by the sections of the Act which empower a court to "go behind the bond," and settle people's affairs in a way they never contemplated. He obtains an assent to a certain sum as due before the conciliator no less readily than to a renewal of a bond in his own shop, and the certificate thereon granted virtually shuts out further controversy. No cause can be shown why "the agreement," which the debtor must admit, "should not be filed," and once filed it becomes a decree.

It is no wonder under these circumstances that the applications to the conciliators should have been very numerous. The proceeding costs nothing; it holds out the only hope of fair treatment to the creditor; it is the only avenue by which in a suit against an agriculturist the court can be reached. Yet the working of this elaborate machinery seems to bring matters in the main to almost exactly the same point they would be at without it. The 16,000 cases out of 29,000 in which conciliation was tried and wholly failed, represent the old proportion of contested suits quadrupled by the debtors having no cost to pay for an unconscientious defence.

The two advantages of the conciliation system are that in general the conciliator is rather nearer than the court to the debtor's house, and that no court fees have to be paid. On the other hand, the conciliators being scattered about at places not convenient for the class of creditors, the latter are harassed by repeated and too often fruitless attendances which interfere with other business so as to cause considerable loss. For this the borrowers must in the end pay, if borrowing continues at all. When conciliation fails, as it does in the great majority of cases, the creditors' time and travelling expenses have been thrown away; the debtor has been deprived of three or four days' earning for nothing; and the witnesses who have been prevailed on to attend, have been subjected to useless and vexatious harassment, if not to actual want.—*Pioneer.*

MADRAS SCHOOL OF AGRICULTURE.

A MADRASSEE, or a dweller in the plains of South India must have buried himself in some very unaccommodating corner, if he has not at one time or another heard of the Madras School of Agriculture and of Mr. Robertson, its Superintendent's strenuous efforts for a number of years to remove some of the old land-marks of native conceptions of agriculture. Taking the Indian agricultural class as a body, it is impossible to exaggerate the ignorance in which they move and live. As they work on their several holdings, the external world and the prospects of a good or a bad harvest have some hold upon them through the medium of their senses, but to all those higher sources of intellect which lead to an examination of the several objects they ought to be interested in, they are perfect strangers. The high lights of the picture of agricultural life presented before them by Mr. Robertson, throw but into deeper gloom their own startling ignorance, and though it seems cruel to provoke them to wrath by ridiculing and exposing to ridicule, the crudities of thought and practice they have fallen into true benevolence, to them suggests that the picture of their ignorance should be drawn with no sparing hand. To what a high degree of proficiency the Madras School of Agriculture has attained is shown by a pamphlet, which we have received, containing the "Question Papers of Class I. of 1876 in the Madras School of Agriculture." Eminently practical in their character, and admirably suited to test the thinking powers and the capacities of his students generally, no one can rise from even a cursory glance at them without feeling convinced that a thorough knowledge of the various subjects mentioned in the papers cannot but constitute a scientific agriculturist in every sense of the term. Economically considered, the country has been too long a sufferer to the agricultural charlatanry which it has been a victim to, and Mr. Robertson has never ceased to point the means of escape from the dangers of a neglected agriculture. Field chemistry and geology are points which Mr. Robertson very justly lays much stress upon. They are subjects which the ordinary ryot treats with huge disdain, and the various papers set for examination show that the Superintendent of the Government Farms is anxious, beyond all things, to impress on the minds of his young pupils that Nature has no superfluities, either organic or inorganic, and that certain processes whose utility may not be apparent to us at first sight or thought either, are as necessary to the comfort of animal life as is the food that such life is supported by. Mr. Roberson leads with some very practical questions as to benefiting the soil by hoeing, deep tillage, and the conditions under which crops benefit by the latter. He has omitted no pains, apparently, in the analysis of waters, and expects his class to be able to determine the difference between hydrostatic water, capillary water, and hygroscopic water. Manures, and the several gases that go to form a fertile field, in short all the elements of plant food, are

points on which he must have well grounded his class, to expect it to be proficients. Flax and wheat, sugar, cotton, and maize are crops whose scientific cultivation he urges the necessity of, while the growth of tobacco, hemp, and fibre of all descriptions on principles better calculated to develope them to their fullest capabilities could not have been omitted in his lectures. Coffee loses none of its importance by the side of cereals and fodder-producing plants. Farm implements and gear generally are matters Mr. Robertson thinks his class ought to be adepts in ; and, looked at from every point of view, the portion of questions set by him shews that there is no part of a farm, no concern of it, however petty it may be, that has not a recognised and highly important function to discharge. Doctor Western's paper on veterinary science follow those of Mr. Robertson They are of a highly professional character, and extend to all matters connected with animal life on the farm either in health or disease. He is critical in the use of terms employed in the pharmacopœia of veterinary lore ; and the general tenor of his paper denotes the inestimable value he sets upon cattle and the condition of perfect freedom from disturbing influences he would see them in. Mr. Hamilton's questions on chemistry are proof of the high standard of perfection to which the class must have attained to be able to answer them. A discriminating intelligence alone could enable a student to pass through them successfully, and we feel certain that the questions demanding an explanation of the different kinds of acid known to the field chemist are meant to be some thing more than tentative. Mr. Wilkins follows with a string of very pretty questions on botany, and we would fain hope that the replies received were significant of the value the class attached to that branch of Nature's choicest gifts which the science of botany illustrates. Wiser than our ancestors in not a few respects, it is an unmistakable evidence of triumph of modern botany that we no longer labour with them in the ignorance which once existed with reference to a thousand discoveries that the science has made known in those latter days. Dr. Kyes's questions on zoology are searching and interesting at the same time ; and the habits and characters of the animals he calls upon the students to classify cannot be contemplated with indifference. We have left ourselves but little space to notice the papers on Physical Geography, Arithmetic, and Book-keeping, Mensuration, and Building set severally by Mr. Ganapati Iyer and Seetharam Moodelly Garoo, and have only to add by way of concluding remarks that the little volume contains matter which we would give the students of class I, of the Agricultural School the full credit of being thoroughly acquainted with.—*Madras Times*,

SEWAGE FARMING IN THE PEOPLE'S PARK.

THE public of Madras have been brought under so many municipal saws and harrows that they have become quite resigned to whatever further trials of temper the city Archons may choose to inflict on them. All Madras rose as one man when a proposal was made some years ago to give up a portion of the Park to suit railway conveniences, and meet railway requirements. There were giants in those days, and they determined that Madras should not lose one inch of its park for any man, be he King or Kaiser. Resolutions were made, which the great Indignation Meeting was afterwards to carry ; they were freely canvassed everywhere before the eventful day—" upstairs and downstairs, and in my lady's chamber ;" and the upshot of the matter was that the citizens of Madras triumphed. But they have become very meek apparently since then, and make no stir now when a project is being carried through of converting a portion of the park into a sewage farm. The site chosen for the purpose is one near the Napier drinking-fountain, and almost contiguous to a public thoroughfare affected by all classes and conditions of men, from the highest to the lowest. The sanitary results of the utilization of sewage in the manner proposed to be done is a question which ought to be at once and for ever decided, there being so many and such conflicting opinions on it. French *savants* appear to be equally devided with our own experts in their judgments. Six or seven years ago, the inhabitants of a French village near Asnières grew nearly frantic when it was intimated to them that sewage irrigation would at no distant day be brought within their senses of sight and smell. They instanced the case of the port of Marseilles into which sewage had been diverted, and which proved a terrible calamity to the people there, having been found provocative of disease. They urged that if so undesirable a result should have overtaken a measure that made the briny element a receptacle of a city's whole sewage, the result might be incalculably worse were the objectionable matter spread over a surface of land, no matter how scientific the process might be which sought to render it innocuous. The Prefect of the Department, on the other hand, saw nothing really to warrant the people's suspicious and fears, and his opinion carried the day ; the consequence was that they one and all shunned the evil spot, ground rents in its neighbourhood fell alarmingly, and it took years to convince the people that a sewage farm need not be the *bête noire* it was made out to be. Be these facts as they may, we cannot help deprecating the uses to which the People's Park, the very lungs of the city, is to be condemned, and we trust our expression of dissent from the project may not be the only solitary one.—*Madras Times*.

IRRIGATION.

THE subject of irrigation has recently occupied a considerable share of attention. It is astonishing to observe the diversity of opinions, which the discussion has called forth. There is the party who hold that we cannot possibly have too much canal irrigation ; another group have no objection to irrigation but object to the canal system ; they advocate well irrigation, and so on. We ourselves do not approve of canal irrigation, but only as at present managed. We see no objection to the use of canal water. What we object to is its abuse, and under the present system, that is unavoidable. A cultivator applies for water for his wheat, a day is fixed, and the water is turned on. Knowing, as he does, that a considerable time must elapse, ere he gets any more, he floods his fields to the depth of 12 inches or so. Now, this is in utter defiance of all Nature's arrangements or intentions. By means of high retaining ridges, enclosing the fields, all this water is compelled to percolate into the soil. When such a quantity of rain falls, we have fears of a famine from flooded lands ; but the ryot, through some greed, deliberately attempts to destroy his crop, in order that he may get full value for the canal rate he has to pay. Eight or ten days afterwards the same process is repeated, and if the crop does not rot in the field, the fault is not the cultivator's. This is the fault of the system, the buyer of water is charged so much per acre, instead of so much per thousand gallons. Were the latter system adopted, the ryot would not, through greed, overflood his fields, he would carefully take just what he thought would suffice, and his land would not suffer so much by this quantity being a trifle short, as it would by an excess of water being given to his land. It might be that the individual crop would suffer a little more, but succeeding crops would not, nor would *reh*, or other pests, get the upper hand, and no one knows this better than the ryot. If the canal water could be dealt out to the cultivator, at the rate of one inch, or even half an inch in depth at a time, and oftener we should have no fear of the deleterious effects of canal water. It is this flooding in excess we deprecate. Another objection to the system of distributing water from these canals is the length of time which elapses between each watering, When the weather is hot, the earth gets caked and hard. The lime held in solution, by all the canals fed from the Himalayan streams, is urged as another fatal objection to the use of this water. We do not see any harm that this would do, were the water applied in moderation. Water heavily charged with lime is not good for growing tea, although it does not seem fatal to young seedlings ; but, as a rule lime is not an objectionable material for growing crops generally. One other objection, and we have done. The villagers universally use the canal water for drinking and cooking purposes, and for such purposes it is unspeakably dirty. Let us now see what well irrigation promises to do.

There are two sorts of wells known and in use among cultivators—*kutcha* and *pucca*. These names require little explanation. The *pucca* well is, as its name implies, built of solid masonry to the bottom, and usually has an inside diameter of six feet, and a depth regulated by the supply of water in the subsoil. In some districts 40 feet is a fair depth ; while in others, to get anything like a steady supply, the well has to be 100 feet deep. Now, if we take 60 feet as the average depth of these wells, we arrive at an average cost of each well of Rs 600. As each of these wells is estimated to supply sufficient water for 50 acres, the cost per acre would be Rs. 12, which is equal to an annual charge of, say annas 10, interest being calculated at the rate of five per cent. per annum.

The second mode is the *kutcha* well, which is simply a deep hole dug in the corner of a field, and which fails, when most wanted, the depth seldom exceeding 12 feet, and the whole affair collapsing under a heavy fall of rain. There is, indeed, a third kind, called the *kutcha-pucca* made to the depth of 20 feet, and usually lined with rings of burnt clay, which hold the sides apart for a couple of years. Both of these latter are but temporary at the best, and on account of the continual renewals, rendered necessary by the frequent collapses, are very expensive in the end.

We may endeavour to institute a comparison as to cost between canal and well irrigation. Canal water, we know, costs one district with another about Re. 1-8 per *fasl*, or say Rs. 3 per acre per annum. Well irrigation then costs only 10 annas as against Rs. 3 ; but to the former charge falls to be added the cost of raising the water, and it is quite impossible to assess this, as the cultivator does not place a high value on the labour of his bullock, or on his own ; because he has not to pay hard cash for it. This, of course, is wrong ; whether he has to pay or not, a definite value attaches to all work of this sort done by himself or his cattle, as if they, the latter were not at this work, they might be ploughing, or be otherwise employed. There can be no doubt that if we assess a fair value as due to the work of the cattle, well irrigation will not be much cheaper than canal watering. The ryot, however, will not deluge his lands, as the raising of any water in excess of his actual requirements means a considerable amount of labor for himself and bullocks, and he, will think twice ere he exerts himself needlessly. The advantages to be looked for from well irrigation are many and valuable. If of the proper depth, there should be no intermission in the supply, which is often the case with canal water ; an increased demand in an unusually dry season, resulting not unfrequently in many cultivators being unable to get any, at the very season when a little help in this way would save their crops. The well would always be at hand, and able to supply water at any moment the ryot chose to wish for it. We have known whole fields destroyed from want of one watering at a critical period, and once saw fifty acres of oats, which had been grown by an European tea planter for his cattle-food, utterly ruined in this way. The canal, with a plentiful supply of water, passed through his fields, but was reserved under some

previously made arrangement, for a couple of villages a mile beyond his place. The result of this want of water was that the cattle were ultimately turned in to graze among the oats, the crop being so seedy as not to be worth the expense of cutting. Again, the great, and in many cases fatal evil of overflooding would be entirely got rid of. No man would be so foolish as to put himself to the trouble and expense of raising more water than he imagined good for his fields. In many instances, ploughing is delayed by the ground being too hard, and it frequently happens that, at this particular time, no canal water is available for flooding. With his own well, the cultivator could have water at any time. And now we come to what appears to us the chief advantage of wells for irrigation, although it is not exactly connected with the subject of watering crops; and it is the value of those wells from a sanitary point of view. We believe that bad drinking and cooking water is perhaps the most common pre-disposing cause to fevers. This subject does not appear to receive any attention, when the question of water-supply is under consideration. One has only to live a short time in the neighbourhood of a canal to see how universally its water is used for all domestic purposes. He will then, perhaps, understand those sudden, and, in many cases, unaccountable, outbreaks of sickness, which travel over the country, decimating its inhabitants. To him they will not appear inexplicable. These wells scattered at close intervals all over the face of the country will always be at hand to furnish him with domestic water supplies. The recent investigations of the French, in the direction of artesian well, open up an entirely new view of this question of well irrigation, which calls for more attention than it has hitherto received.—*Indian Daily News.*

RUBBER IN BRAZIL.

In *Scribner's Monthly* for June 1879, appeared an interesting paper on "The Mediterranean of America," in which the writer described a trip up the mouth of the Amazons. At the beginning of the paper the town of Breves, situated in the midst of deadly swamps, but prosperous from its rubber industry, is referred to, and the following account is given of the method of collecting and treating the milk of the rubber trees:—

In the early morning, men and women come with baskets of clay cups on their backs, and little hatchets to gash the trees. Where the white milk drips down from the gash they stick their cups on the trunk with daubs of clay, molded so as to catch the whole flow. If the tree is a large one, four or five gashes may be cut in a circle around the trunk. On the next day other gashes are made a little below these, and so on until the rows reach the ground. By eleven o'clock the flow of milk has ceased, and the *seringueiros* come to collect the contents of the cups in calabash jugs. A gill or so is the utmost yield from each tree, and a single gatherer may attend to a hundred and twenty trees or more, wading always through these dark marshes, and paying dearly for his profit in fever and weakness. Our *mameluca* hostess has brought in her day's gathering—a calabash full of the white liquid, in appearance precisely like milk. If left in this condition it coagulates after a while and forms an inferior whitish gum. To make the black rubber of commerce the milk must go through a peculiar process of manufacture, for which our guide has been preparing. Over a smoldering fire, fed with the hard nuts of the *tucumá* palm, he places a kind of clay chimney, like a wide-mouthed, bottomless jug; through this *boião* the thick smoke pours in a constant stream. Now he takes his mold,—in this case a wooden one, like a round-bladed paddle,—washes it with the milk, and holds it over the smoke until the liquid coagulates. Then another coat is added, only now, as the wood is heated the milk coagulates faster. It may take the gatherings of two or three days to cover the mold thickly enough. Then the rubber is still dull white, but in a short time it turns brown and finally almost black, as it is sent to the market. The mass is cut from the paddle and sold to traders in the village. Bottles are sometimes made by molding the rubber over a clay ball, which is then broken up and removed. Our old-fashioned rubber shoes used to be made in this way. Twenty million pounds of rubber, valued at $5,000,000, are annually exported from Para; in the dry season many thousand people are engaged in gathering it. But the business is altogether a ruinous one for the province, as Brazilians themselves are fully aware. The *seringueiro*, who gains two or three dollars from a single day's gathering, has enough, as life goes here, to keep him in idleness for a week; and when his money is spent, he can draw again on his ever-ready bank.

The present wasteful system is spoken of as follows:—

The half-wild *seringueiros* will go on submitting to impositions and dying here in the swamps, until Brasilians learn that by purchasing this land from the Government and planting it in rubber-trees, they can insure vastly larger profits, and do away with the evils of the present system. It is what must eventually be done. The rubber gatherers, in their eagerness to secure large harvests, have already killed an immense number of trees about the Pará estuary; they have been obliged to penetrate farther and farther into the forest, to the Tocantins, Madeira, Purus Rio Negro, and eventually even these regions must be exhausted, unless they are protected in some way. The trees, properly planted and cared for, will yield well in fifteen years, and, of course, the cost of gathering would be vastly reduced in a compact plantation; half the present labor of the rubber collector consists in his long tramps through the swampy forest.

THIN SEEDING.

Full and healthy development is essential for maintaining in the highest state of perfection those qualities for which improved plants and animals are esteemed by man. Our cereals—wheat, oats, barley, rye—are all the products of man's care and skill as a cultivator, and only by the continued exercise of that care and skill can the qualities they have acquired be retained. The tendency under neglect to revert rapidly to the wild type is most marked in the oat. Thick seeding tends to promote this degeneracy, and cause a diminished yield of grain. On this interesting and important subject Professor J. P. Roberts, of Cornell, U.S., in the *Rural New Yorker*, gives the results of last year's, and the average results of five years' experimenting with the oat. The experiments were conducted on moderately poor land the average yield of the experimental plots being about half as much as the regular field crop. The following is the table of quantities:—

THICK AND THIN SEEDING, 1880.

	Yield per Acre. bush.	lbs.
Seven pecks of seed per acre	24	12
Twelve pecks of seed per acre	21	3
Sixteen pecks of seed per acre	18	9
AVERAGE THICK AND THIN SEEDING.		
Four years, 5 pecks per acre	39	20
Five years, 7 pecks per acre	38	9½
Five years, 12 pecks per acre	38	10
Five years, 16 pecks per acre	37	12
1880.		
Average of broadcast plots, 7 pecks per acre	36	18
Average of drilled plots, 7 pecks per acre	30	15
GENERAL AVERAGE FOR THREE YEARS.		
Broadcast	49	4
Drilled	43	7½
1880.		
Treated with salt	31	12
Treated with plaster (gypsum)	31	23
Adjoining plots unfertilised	27	13½
GENERAL AVERAGE FOR THREE YEARS.		
Salted ... :	40	16
Plastered	37	9
Unfertilised...	36	7
1880.		
To plot No. 9 were applied 600lbs. of equal parts of salt and plaster	37	1
Plot No. 8 on the one side, unfertilised	29	17
Plot No. 10 on the other side, unfertilised	28	19
Average of the two (No. 8 and No. 10)	29	2

Thus it appears that last year the use of seven pecks of seed per acre gave a yield of 6 bushels 3lbs. more than was obtained by the use of 16 pecks of seed, the difference in favour of thin seeding—including the saving in seed—being eight bushels 13lbs. Then, again, an average of four years shows a gain—inclusive of seed saved—of five bushels 7lbs. per acre by the use of five pecks of seed instead of 16 pecks; and the average of five years shows three bushels 6½lbs. per acre in favour of seven pecks of seed, as compared with 16. The result of broadcast sowing with the same quantities of seed as compared with drilling, are striking, the average of three years giving five bushels 36½lbs. in favour of broadcast sowing. The effect of salt and "plaster" and plaster, used as fertilisers separately and in combination, is also worth nothing. Professor Roberts says:—"It appears from the results that either plaster or salt, or both, have the property of preventing evaporation, or of drawing moisture from the atmosphere. They probably perform both offices." I have a neighbour who will be delighted to ponder over the foregoing experiments, and they merit the serious consideration of all grain growers. My neighbour is a staunch advocate of thin seeding. His practice is to sow one bushel of oats and about 50lbs. of wheat to the acre, and he maintains that he harvests five bushels per acre more grain than he would if he used double the quantity of seed on the same land. He is an old farmer and speaks from 27 years' experience in this colony His thin-seeding ideas he brought from the old country, where he had also experienced the benefit of saving seed and increasing the yield of grain. Professor Roberts now intends to select the best land for his experiments in thick and thin seeding, so that in a few years he may obtain data for a double comparison. Now, if a series of such experiments as the above were instituted at Dookie, carefully conducted, and demonstrating the wisdom of thin seeding, thereby saving, say, 500,000 bushels of seed annually, besides an increase of three or four millions of bushels of crop, why, the endowment of the place with a grant of two or three hundred thousand pounds would be a more bagatelle compared with the benefit that would be conferred on the community. Moreover, experiments in manures could be carried out at the same time for the purpose of ascertaining the best, and cheapest means of maintaining the producing power of the soil.—*Australasian.*

AMERICAN CROP REPORTS FOR 1879.

The census for the cereal product of 1880, which is the crop of 1879, has been completed, and it shows the constantly increasing prosperity of the country. The total wheat and corn crop is 2,332,079,681 bushels. The total rye, oats, barley, and buckwheat is 481,905,000 bushels, The total product of the country aggregated 2,714,603,681 bushels. This

is a remarkable increase in the productions of cereals during the last decade. During the last ten years Indiana and Illinois have nearly doubled their wheat production. Iowa has quadrupled hers, Minnesota doubled Wisconsin suffered a loss of about 1,000,000 bushels. Kansas increased, eight fold, and Nebraska and Colorado sevenfold. The following are the complete returns of wheat and corn as compiled by the Census Bureau for 1880 :—

	Wheat, 1880.	Corn, 1880.
Ohio	46,011,869	112,681,146
Indiana	47,288,9 9	117,121,915
Illinois	51,136,455	817,796,895
Michigan	35,537,097	86,844,229
Iowa	31,177 225	276,093,195
Wisconsin	24,884,689	35,191,464
Minesota	34,625,675	14,979,744
Missouri	24,971,727	203,464 820
Kansas	17,324,141	106 790,482
Nebraska	13,846,742	65,785,572
Colorado	1,475,559	455,988
Dakota	3,018,354	2,078,9 9
Moontana	469,688	5,794
Nyoming	4,752	65,0 0
Idaho	510,564	16,408
Utah	1,167,268	161 244
New Mexico ...	708,788	650,854
Arizona	189,517	36,246
Washington ...	1,921,382	39,966
Nevada	70,404	12,891
Oregon	7,486,492	127,675
California	28,787,133	2,050,007
Total ...	272,617,511	1,303,188,529

Total for the country : Wheat and corn. 2,232,679,631 ; rye, oats, barley, and buckwheat, 481,9 5,000. Total 2,714,684,681.

IMPORTANCE OF MINERAL ELEMENTS OF FOOD.

"THE more a man follows Nature," says Hufeland in his Art of Prolonging Life, "and is obedient to her laws, the longer he will live ; the further he deviates from these the shorter will be his existence. Nature has ready prepared abundance of food for man, and if he partakes of them as he has need in nearly the form offered, there is no danger of getting far out of the way. The art of man however steps in and changes, takes from and refines many articles of food, so that their original constitution is materially changed. How far such changes modify the healthfulness of food is a proper subject for inquiry.

Wheat as furnished by Nature, is a wholesome and most valuable food. In early times it was boiled until soft, or ground and made into bread, furnishing the people with a healthy food. In later times to gratify the taste and please the eye, it has been customary to separate all of the bran portion of the ground wheat, leaving only the white and fine particles for the making of the bread. One hundred pounds of wheat when ground will make about 76 pounds of flour and 20 pounds of bran. The flour contains of albuminoids as tissue making elements 1·65 per cent., and of phosphates and other salts 0·70 per cent., making a total of 2·35 per cent. The bran contains of albuminoids or tissue, making elements 3·10, and of phosphates and other salts 7·05 per cent., making a total of 10·15 per cent. In other words the bran for the purposes of nutrition is four-fold richer than the flour, the twenty pounds of bran made from 100 pounds of wheat containing more nutriment than the 76 pounds of flour. The flour consists chiefly of starch, while the flesh forming elements together with the blood and bone producing constituents are principally rejected in the bran. It will be observed that nearly all the phosphates and other salts are removed from the flour in grinding leaving only 0·70 per cent., while the bran contains 7·05 per cent. of these important elements.

Is it probable that so large a proportion of the mineral elements of wheat can be thus rejected without ill effects to those who live largely upon a diet of flour bread ? This is an important question for consideration ; complete data for the decision of the question are not at present available, but some important facts have been established.

Numerous experiments in feeding farm stock have shown that when animals are fed in food from which the phosphates and other salts have been removed as completely as possible, they become sleepy and weak, especially in the extremities and finally die from lack of mineral food, although the quantity of organic food eaten and digested may be amply sufficient to sustain life. The digestion of food did not seem to be interfered with, and when the animals were examined after death, all the organs appeared healthy and well nourished. Now if such marked and fatal results attend the removal of the phosphates and other salts from the food of domestic animals, is it not probable that the removal of nine-tenths of these same elements from wheat in the process of the manufacture of flour would be attended with injurious effects. Especially would this seem probable where children who while growing need large supplies of flesh, blood, and bone material, are fed largely upon flour bread. Is it not probable that many of the pale, poorly nourished children, with small, flabby muscles, owe something of their condition to their diet of flour bread? Not all of the fat and plump children are really well nourished as is shown by the smallness of their muscle development, and their general inability to withstand fatigue or disease. Fat is not muscle, and does not impart strength.

Is it not a significant fact that there should be comparatively so little disease among our domestic animals—so rare that one dies, so rare that the young fail to grow up—while there is so much sickness among human beings, and so large a proportion die before they are five years old ? When any of the domestic animals are sick, we attribute their sickness to improper food, or wrong management of some kind, and seek to remedy it. If one of them dies, we do not say it is a "wise dispensation of Providence." We generally believe that there has been carelessness or mismanagement somewhere. As regards the human family, we seem to take it for granted that there is to be a large amount of sickness, and do not trouble ourselves very much to ascertain the cause of it. Inasmuch as the natural period of the life of man is longer than that of the domestic animals, it would reasonably be expected that the young of the human family would be endowed with a greater degree of vitality and be less likely to die young. The fact that one child in every five of those born dies before it is a year old, and that one-third of all the children die before they are five years old is full of significance and worthy of consideration If one-fifth of all the calves born should die before they become a year old, we should have a Government commission appointed to investigate the causes of the mortality ; but the children continue to die and no one thinks of having the causes investigated.

It may be suggested that the eating of flour bread can have nothing to do with the death of children under one year of age, as they do not indulge much in that kind of food. True they do, not or should not eat bread of any kind but their mothers do and a mother who lives largely on flour bread does not obtain enough bone and blood-making material to form a healthy body for her child and her milk is nearly as poor in mineral elements as the flour bread which she eats. Thus, indirectly even the infant may suffer from the removal of the phosphates from the wheat in grinding it.

Disease in plants is found to be associated sometimes with a deficiency of mineral elements of food in the soil. The potatoe rot has been ascribed by good authority, to a deficiency of lime and magnesia in the soil The amount of magnesia in the ash of sound potatoes is 5 to 10 per cent., while in diseased tubers it was found to be less than four per cent. Of lime, sound potatoes contained only 1·77 per cent. Diseased orange trees found by Professor. Thorpe to contain a deficiency of lime and magnesia. If a deficiency of mineral elements is associated with disease of plants, it is highly probable that a deficiency of necessary mineral elements may be a cause of disease in the human system If the removal of the phoshates and other mineral elements from the food of domestic animals causes them to die certainly it is at least propable that the removal of so large a proportion of the mineral elements from wheat, in the process of grinding, may exert a deleterious effect upon the health of those subsisting largely upon it, It is a subject worthy of further attention.—*N. E. Farmer.*

THE HIGHLAND SOCIETY'S EXPERIMENTAL STATION AT PUMPHERSTON.

THE Highland Society's experimental station at Pumpherston, near Mid-Calder, was visited yesterday by a number of gentlemen, to whom the various experiments now in progress, to test the relative crop-producing value of different kinds of artificial manures, were explained and commented upon by Dr. Aitken, Chemist to the Highland Society. The present is the fourth year of those experiments, and the observations made have already thrown considerable light on this important branch of scientific agriculture, all the results of each season's trials having been carefully noted and collated. As at the Highland Society's other experimental station at Longniddry, there are at Pumpherston ten acres under experiment, the field being divided into 40 plots of one rood each. The cropping is a rotation of turnips, barley, grass, and oats ; and this year the crop is oats Before conducting his visitors over the station, Dr Aitken explained that the manures experimented with might be divided into three great classes—phosphatic, potassic, and nitrogenous. Of phosphatic manures there was a considerable number in the market. The whole world was ransacked to find phosphates to add to the fertility of the soil, and the question before the farmer was, which of these phosphatic manures was the best. There were here under observation five different kinds of phosphates, divided into two sections—the one dissolved and the other undissolved. On every plot on the station there was applied exactly the same amount of phosphoric acid, potash, and nitrogenous material, so that if all the manures were equal in their action there should be no difference to be seen in any of the plots, with the exception of one or two where certain ingredients had been purposely omitted. All the plots were sown on exactly the same day. Beginning with the plots to which the various forms of undissolved phosphates had been applied, Dr. Aitken pointed out that the first plot exhibited the products of bone ash, with of course, the uniform proportion of potash and nitrate of soda. To one rood of ground 20lbs. of phosphoric acid was applied, with 15lbs. of potash, and 10lbs. of nitrogen, these figures being equal to 80lbs. of phosphoric acid per acre, with 60lbs. of potash and 40lbs. of nitrogen. Of course, in order to get those 20lbs. of phosphoric acid it was necessary to apply about 60lbs. of bone ash. The next plot showed the results of ground coprolites. On both these plots the crop was a little late and rather short, but on the whole a fairly promising display. The crop grown from bone dust, which was

the next inspected, seemed riper and likely to thrash better than either of the first two lots, though their was less straw. Phosphatic guano had produced a good heavy crop of grain—heavier, probably, than any of those already mentioned. The fifth plot treated with phosphatic manure was that on which ground apatite had been applied. This is a purely mineral phosphate, containing a high percentage (74) of phosphate of lime, and capable of being ground down to an exceedingly fine powder. The results, however, were not so satisfactory as in the other phosphatic plots, the straw being short and the crop small. In the adjoining plot there were no phosphates at all, only potash salts and nitrate of soda having been applied; yet the crop seemed on the whole decidedly better than that grown from the apatite. In a line with these plots, treated with undissolved manures, were plots on which the same manures, dissolved, had been applied, the object of this experiment being to test the results of chemical as compared with mechanical means of dividing the phosphates. The outcome was to demonstrate pretty clearly that (for such soils, at all events, as that at Pumpherston—a clayey and rather poor soil), the dissolved phosphates were decidedly superior. The oats on the plots treated with dissolved phosphates were from a week to ten days in advance of those fed with the undissolved phosphates, while the yield also appeared much heavier. This is an important point for farmers using artificial manures. Much, of course, depends on the conditions of soil and climate, but it seems obvious that for late districts the dissolved phosphates would be most suitable, as by bringing the crop forward a week or ten days earlier, the grain might be saved where it would otherwise be lost in a wet or backward season. The same result might not necessarily follow in an earlier district; but this is a point which farmers could easily settle for themselves by experiments similar to those at Pumpherston, to encourage which, indeed, is one of the objects Dr. Aitken and the Highland Society have in view. The point in question—the superiority of the dissolved manures for certain soils and climates—was considered by all present yesterday one of the most valuable lessons taught by these experiments. The crops grown with dissolved phosphates were undoubtedly the best in in the field.

There are six plots of nitrogenous manures. Nitrate of soda and sulphate of ammonia have both produced excellent crops—the produce of the latter being probably the superior. An interesting feature in this section was the horn-dust plot which had produced surprisingly good results. This year shoddy, which was experimented within previous seasons, was abandoned altogether, having in Dr Aitken's opinion, been proved utterly useless as a manure. In its place horn-dust was applied. It was ground as fine as possible, and in the event has proved a capital nitrogenous manure, the crop being in some respects equal to any in the field. It was applied along with the potash salts and bone ash, superphosphate. Dried blood produced a miserably poor crop—so poor, indeed, that doubts were suggested as to whether the manure had not by some mischance been omitted altogether. In one of the plots no nitrogen was applied, but merely potash and phosphates, and the crop was almost nil. Three superphosphate plots afforded interesting evidence with reference to the efficacy of dissolving these manures. Ten, twenty-five, and forty per cent. of the manure applied to those respectively was soluble and the results showed unmistakably that the dissolved superphosphates produced a very much better crop. A curious result was brought out in one of the plots, showing the danger of overdosing crops with dissolved manure. In one or two plots two-thirds of the manure was applied on one-half of the rood and the remaining third on the other half, there being thus double the quantity on one part that there was on the other. The result in the case referred to was that the ground which had received a double portion of dissolved bone-ash, with a mixture potash salts and sulphate of ammonia, produced a decidedly poorer crop than the part which had received exactly half as much of the same manure. The oats had quite a burnt appearance, and were inferior in every respect, and this was regarded as striking evidence of the deleterious effects of too much dissolved phosphates. The experiments with superphates showed that these, when highly dissolved, gave a better yield than when less dissolved, and this result was pointed out by Dr. Aitken as going to disprove the theory of certain experimentalists who hold that insoluble phosphates were really better than soluble. Ichabo guano gave a good, uniform, well-ripened crop, and Peruvian guano also an even though not a heavy yield. Fish guano also seemed to produce a better crop than in former experiments, which, Dr. Aitken observed, appeared to indicate that this manure took some years to tell upon the soil, but that it possessed considerable manurial resources. At the close of the visit a vote of thanks was awarded to Dr. Aitken on the motion of Mr. Stewart, Secretary of the Western District of Mid-Lothian Agricultural Association, seconded by Captain Norman, R. N., Berwick-on-Tweed.—*Scotsman.*

THE HARVEST OF THE WORLD.

THE volume of reports on the harvest in the different countries of the world which is brought out by M. B. Estienne every year, is now being issued. It is a large quarto volume of over 800 pages, and a very handsome map in colours showing the state of the wheat crop in the various departments of France is published with it.

The first portion of the volume deals with the various crops in France reports being given from the various departments. The wheat crop is reported on from 90 departments, and in three of these it is said to be very good, in 30 good, in 23 fairly good (*assez bonne*), in 24 medium (*mediocre*), and in 10 bad. Last year the figures were—5 very good, 17 good, 26 fairly good, 16 medium, and 6 bad; so that it will be seen that the reports are this year from over a larger area and also indicative of a better crop than last year. Of barley we have reports from 70 departments, 8 of which are very good, 38 good, 18 fairly good, 1 passable, 14 medium, and 1 bad. Last year's figures showed this crop to be very good in 26 departments, good in 40, fairly good in 5, and medium in 8. This year's crop, it will be seen, is not so good as that, but is still fairly good. Maize is not largely grown, except in the southern parts of France, and only 25 departments (as against 33 last year) report on it. The crop is a very ordinary one, being good only in 7 departments, fairly good in 5, medium in 6, and bad in 7. Last year this crop was a very good one—3 departments reporting is very good, 19 good, 5 fairly good, and 6 medium. Oats are reported on from 81 districts; in 6 they are very good, in 21 they, are good, in 18 they are fairly good, in 26 they are medium, and in 10 bad. Rye is declared to be a very good crop in 6 departments to be good in 19, fairly good in 17, medium in 16, bad in 5, and very bad in 2. Last year's reports showed oats to be very good in 28 departments, good in 40 departments, fairly good in 7, middling in 6, bad in 2, and very bad in 1. And rye at the same time was reported as very good in 11 departments, good in 61, fairly good in 6, and medium in 8. From the whole of these figures it will be seen that the crops of this year are not up to those of last year, but that wheat is not much below the crop of an average year. None of the crops will be very bad, and none can be described as very good.

The crops in Great Britain are described as—wheat, 10 per cent. below average and likely to realize only about 10 million quarters; barley, 10 per cent. above average; oats 20 per cent. below average; and the year is described as a poor one, and in one in which farmers will not be likely, even though, with a market bare of supplies, wheat is now making a very high price, to recoup themselves for any of their losses of the past five years, even where they do not add to the n.

In Austria-Hungary the crops are spoken of as all round good, wheat and barley being both above the average. Rye is very much and oats slightly, under average. The reports from Italy all agree in describing the crops of a medium character and much below the abundance of 1880. The markets, too, are calm, and prices feeble. Of wheat the quality promises to be good, but under the ordinary weight. Oats are good in quantity and quality, although the grain is not so plump as last year. But little barley, is grown, but where it is it is this year of bad colour and lacking in weight. Rye is good and abundant and will be the crop of the year. From the Turkish provinces in the Danube comes the statement that this year's wheat harvest will be of a medium character, and the qualities of the grain various. Rye will be good and abundant. Barley is yielding a good crop for quantity, but both colour and weight are bad. Oats here will be very much above the average.

All the reports from Russia, and especially those from Odessa speak of the barley crop as the best crop of the year, doubling that of last year in quantity, but as a rule the grain is not so plump and weighty, nor the colour so good, as might be wished. Rye is an abundant crop, and wheat is also good. Throughout Germany the winter and spring sowings are in marked contrast—the former yielding good crops and the latter very defective ones. All crops are very late this year also. Oats are a very good crop, but barley is thin on the ground and the grain is not heavy. None of the crops are an average. In the Prussian States the reports on the crops are by numbers, 100 being taken as representing an average crop:—Wheat 80, rye 77, barley 89, oats 89, pease and similar crops 83; and potatoes, 95. These figures are also as near as possible an average of the crops of the whole of Germany.

Switzerland, right up to the time of harvest, was suffering from an extreme heat and drought that did considerable damage to the wheat, which is a very poor crop this year in consequence. The quality of the grain is, however, very fine. Both oats and barley are good in quantity and quality; but of the latter there is but a small area planted. Rye is a poor crop for grain, but straw is long and good. Belgian reports state that the summer and ripening time was marked by strong rains and a low temperature, the effect of which has been to make the wheat far below an average. Barley is a good crop, both for quantity and quality; and rye is good for quality but under average in quantity. Oats vary in quality, and will be under average in quantity. All crops are reported as bad from Spain, barley being the best. The area under rye is decreasing gradually, and this year it is much smaller than last. Wheat is a very poor crop both for quality and quantity. From Holland all the cereals are reported in good condition. Up to the end of May the weather was unfavourable and all crops suffered somewhat, but the more favourable weather since has had the effect of bringing the produce up to quite an average. Wheat is quite an average, not only in the yield per acre, but also in the acreage sown and the quality and weight of the grain.

All the reports from the United States go to show that in all the States the yields this year will be under an average. In quality, however, wheat is better than last year, while oats and barley are both fairly good in quality and not so much under average as wheat.

SIMPLE WEATHER LAWS.

At a meeting of the Farmers' Club of the American Institute, held recently, Mr. A. J. De Voe, of Hackensack, N. J., sent the following ten short rules by the use of which a person can stand beneath his own vine or fig-tree in any part of the Northern hemisphere (north of latitude 15), and for hundreds of miles around him he can form an accurate opinion how the wind and weather are progressing.

1. When the temperature falls suddenly there is a storm forming south of you.
2. When the temperature rises suddenly there is a storm forming north of you.
3. The wind always blows from a region of fair weather, towards a region where a storm is forming.
4. Cirrus clouds always move from a region where a storm is in progress, towards a region, of fair weather.
5. Cumulus clouds always move from a region of fair weather, towards a region where a storm is forming.
6. When cirrus clouds are moving rapidly from the north or north-west there will be rain in less than twenty-four hours, no matter how cold it may be.
7. When cirrus clouds are moving rapidly from the south or south-west there will be a cold rain-storm on the morrow if it be summer, and if it be winter there will be a snow-storm.
8. The wind always blows in a circle around a storm, and when it blows from the north the heaviest rain is east of you; if it blows from the south; the heaviest rain is west; if it blows from the east, the heaviest rain is south; if it blows from the west the heaviest rain is north of you.
9. The wind never blows unless rain or snow is falling within one thousand miles of you.
10. Whenever a heavy white frost occurs a storm is forming within one thousand miles north or north-west of you.

If any scientific gentlemen has an idea that he can prove any of the above rules incorrect, I am ready and anxious to meet him.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 25th August 1881.

Rajah Souttyanaund Ghosal Bahadoor, *in the Chair*.

The proceedings of the last Monthly Meeting were read and confirmed.

The following gentlemen were elected Members:—

The Rev. Albert Williams, Messrs. E. Delius, W. MacNab, A. Bauermeister and W. D. Pratt, Manager of the Muleng Tea Estate, Assam, and Baboo Ramnarain Chatterjee.

The names of the following gentlemen were submitted for membership:—

The Superintendent of the Chumba State, *viâ* Dalhousie—proposed by the Secretary, seconded by Mr. A. Wilson.

H. Farrer, Esq. C. S., Serajgunge,—proposed by Mr. S. Gowan, seconded by Mr. H. A. Firth.

F. W. Tytler, Esq., Superintendent, Railway Mail Service, Allahabad,—proposed by the Secretary, seconded by Mr. R. Blechynden.

C. A. N. Wallich, Esq., Tea Planter, Julpigoree,—proposed by Mr. G. W. Shillingford, seconded by the Secretary.

Captain T. A. Freeman, 70th Regiment, N. I., Subathoo,—proposed by the Secretary, seconded by Mr G. L. Kemp.

Dr. C. N. Kernot, Calcutta,—proposed by the Secretary, seconded by Mr S. H. Robinson.

Rejoined—Maxwell Smith, Esq., Tirhoot.

Contributions.

1. Review of the Forest Administration for 1879-80, by the Inspector-General of Forests. From the Government of India.
2. On the manufacture of Iron and the future of the Charcoal Industry in India. From the Government of India.
3. Annual Report of the Smithsonian Institution for 1879. From the Institution.
4. Journal of the Asiatic Society of Bengal. Parts 1 and 2 of No. 2, 1881, and Proceedings for June and July. From the Society.
5. A quantity of Orchids from the Dooars. From B. H. Carew, Esq.
6. A collection of Orchids from Sylhet. From C. K. Hudson, Esq.
7. A quantity of seed of the Carob (*Ceratonia siliqua*). From the Director, Department of Agriculture, N. W. P.
8. A small supply of Potato seed of three kinds. From Messrs. Sutton and Sons.
9. Some acclimatized Aster seed. From C. Nickels, Esq.

Garden.

A report from the Garden Committe was submitted. The Committee allude to the economic portion of the garden and to the increased amount of propagation in the Orchard. They allude to the plan for the proposed Plant house; to the steps taken for introduction of a large collection of plants from England and Australia; and to the distribution of plants in future annually to members instead of in arrears of two or three years, which has not been found to work satisfactorily. The Committee add in conclusion that—The garden is altogether in as clean a state as can be expected at this season, and the tanks, especially the western one, fuller than usual at this time of the year, in consequence of the drainage scheme of the Superintendent having worked well; as there are yet two months of the rains remaining there is not likely to be a scarcity of water next dry season.

Particulars regarding Fruits, the produce of Kumaon.

Read the following letter from Mr. W. Lee, of Messrs. Wheeler Brothers, dated Ramgurh and Julna Tea and Fruit Estates, in Kumaon, 6th August:—

On reading an account of the proceedings of the Agri-Horticultural Society at their General Monthly Meeting held at Calcutta, on the 23rd June 1881, as reported in the *Pioneer* newspaper of the 6th July, we particularly noticed the remarks which referred to a "Trial shipment of fruit from Melbourne," and it seemed strange to us that with some of the very finest varieties of English fruit procurable in India, or indeed in any part of the world, within comparatively easy distance from Calcutta, that a trial should not also be accorded to a consignment of the fruit which is produced in our Gardens and Orchards here.

We would briefly point out that the Ramgurh and Julna Fruit Gardens and Orchards were commenced as far back as 1858, since which period annual importations of the choicest fruit grafts from England and America have been made, the result being that at the present time the above Gardens and Orchards are fully stocked with the finest varieties of fruit grown in Europe.

Experience extending over a period of 20 years has amply proved that the temperate climate of the Himalayas is most perfectly adapted for the successful culture of apples and pears, both of which fruits are here produced of far superior size and flavour to similar varieties grown in the cold and damp climate of Great Britain.

We are still increasing our Gardens and Orchards largely, and we now already raise quite a sufficient quantity of fruit to supply the Calcutta market to a considerable extent. The crop of apples alone on both Estates, *viz*, Ramgurh and Julna, averages about 50,000 per annum now which will undoubtedly increase yearly as the succession of newly planted trees come into bearing; and our crops of pears may also now be estimated in the same ratio as the apples, and these will also in like manner increase.

As seeing is believing we would suggest that we be permitted to forward a small case of apples for inspection to you which we should be glad if you would submit for the approval or otherwise of the President and Committee of Agri-Horticultural Society.

The first sample case which we would propose to send from here would be of cooking apples such as are suitable for pies, puddings, dumplings and baking, and we would follow them up by sending samples of our eating dessert apples, which latter would no doubt bear the journey in perfect condition, and we could supply them regularly from August to the end of October. The cooking apples, some of which are very large and are now ready, would be those about which most difficulty might be apprehended as to their reaching Calcutta in perfect condition. The dessert apple would not be so liable to suffer.

The journey from here to Calcutta should from first to last occupy no more than a week, *i.e.*, from the time the fruit be plucked from our Orchards to the time of its reaching Calcutta, and would as soon as the projected Kumaon and Rohilcund Railway from Bareilly to the foot of the Hills is opened, occupy but four or five days.

We have hitherto found a local market for our fruits in Nynee Tal, and have sent small quantities for sale to Simla, Lucknow, Cawnpore, Meerut, Mussoorie, and even as far as Gwalior, and we have found that in most cases our fruits have reached their destination in good and fresh condition, and have been highly appreciated.

If our fruits upon inspection and trial by the President and Committee of the Agri-Horticultural Society be found to be such as we represent them to be and to be worth sending to Calcutta, we should be perpared to forward a large number in the latter part of September and in October to any firm in Calcutta, who would kindly accept the Agency for their disposal.

In conclusion we would beg that our letter and proposal be laid before the President and Committee of the Agri-Horticultural Society, and that a report be made on the subject and also on the quality and condition of the samples of fruits which we would send at the next General Meeting of the Society.

On receipt of your reply we would at once, at our sole expense of course, forward to you a sample or samples of our apples. The pears will be ripe shortly in this month (August).

The enclosed notice will show you the rates at which we have hitherto sold our fruits to purchasers in the plains, the fruits being delivered at Bareilly, which is our nearest Railway Station, at our expense, but in sending large consignments to Calcutta we could no doubt be able to deliver them there at the same rates provided the demand was such that the fruits could be disposed of rapidly as the climate of Calcutta will not admit of their being stored for any length of time, especially during the months of August and September.

Read also a letter of subsequent date (20th August,) from Messrs. Wheeler Brothers from their Julna Estate:—

On the 6th instant, our partner, Mr. William Lee, addressed you from the Ramgurh Tea Estate, regarding the superb apples and pears annually produced in our extensive Orchards, and he suggested sending you samples to be placed before the Committee and duly reported upon. Your reply of the 13th August has been sent to us here, and Mr. Lee further writes to say that he has despatched a case containing samples of apples, pears, some filberts produced at our Ramgurh Estate, and which, we hope, will reach you by the 25th to be in time for your Monthly General Meeting. As we have a larger variety of apples in our Julna Orchards, we beg to advise having despatched by this day's parcel post a small box containing upwards of 40 different sorts of apples, and we feel confident that a more varied or finer collection of fruit has rarely if ever been witnessed in Calcutta. We shall be much obliged by your submitting the sample sent by Mr. Lee, from Ramgurh, and those advised by us, for the approval or otherwise of the Committee at the same time; and as our object in sending the sample is to establish the superior quality of our fruits in the Calcutta market, we hope the opinions of the several members of the Committee will be fully recorded and published in the Proceedings of the Society. Among the sample sent by us we may here mention that Nos. 3, 8, and 14 are Ribston Pippins, Nos. 5 and 10, are the Baldwin, an apple largely exported from America to the Calcutta markets, No. 7, is the celebrated Fall Pippin or white Spanish Reniette, No. 9, the equally well known Reniette du Canada, No. 17, Adams' Pearmain, No. 13, Braddicks Nonpareil, No 22, Pine Golden Pippin, No. 26, Boston Russet, No. 23, the Dutch Mignonne; and we have also sent half a dozen genuine Golden Pippins and the same number of Pommed Apior the little Lady Apple. If you

could kindly arrange to allow the influential residents of the city to examine our samples we should be very thankful.

This collection of fruits was highly thought of by the Members present, the best ever shewn, as the produce of British India. Messrs. Wheeler Brothers add that they have not been selected on account of their size and appearance as specimens, but represent a fair average of our fruits; as far as apples and filberts are concerned. We have thousands of larger apples at this moment in our Orchards. The very few pears we have sent are of our smaller variety, our pears are not yet ripe, and of these we have very fine specimens which will be fit to pluck in about three weeks."

BARLEY RAISED IN THE HIMALAYAS.

Submitted a letter from Captain J. F. Pogson, dated Koteghur, 18th July, of which the following is extract:—

"I have by this day's baughy post sent you two ounces of "*Wheat Barley*," and inspection will show that there are two distinct kinds, one being of the variety raised at Mirzapore by Mr. Nicholson from seed given to one of his servants, and the other being so very like *wheat* in colour and form, as to deserve its name of "*Wheat Barley*."

The zemindars of Kotgurh have grown this Barley, *i.e.*, like the samples sent, from ancient times, and although this place may not be the home of the two varieties of Barley, it has become as common as the other or husked kind, with which it is sown, as I have had to pick out the husked kind.

Thibet may be the home of both kinds, and a traveller from Nepaul may have brought the Barleys, (Mr. Nicholson's variety,) with him to Benares, which is much visited by Pilgrims from Nepaul. If this surmise be correct, both varieties of Barley should be obtainable in the bazars of Katmandoo, and their introduction into the plains of Hindoostan, under Government sanction and support, becomes a very easy and simple affair.

At Kotgurh, the present price of the Wheat Barleys (mixed,) is sixteen seers per rupee, and if the husked kind be picked out, the cost of labor, and reduction in quantity may bring it down to 10 or 12 seers per rupee.

If Nepaul cannot, *or may not* supply the seed, I shall be happy to execute all orders sent through the Society. Officials or Collectors of Districts, could have their indents executed through Major Parry Nisbett, the Deputy Commissioner of Simla, or if they preferred it, I would do the needful.

According to "Ures Dictionary:"—"The weight of the husk of Barley is one-sixth the weight of the grain, or in simpler language is maunds of English Barley, contain one maund of *husk*. Now, as the husk has no nutritive value, it must be admitted that, the price being the same, the purchaser of six maunds of "*Wheat Barley*," obtains one maund, or 82lbs. more of food for his money, than does the purchaser, of six maunds of the common Barley, or to put it in rupees, a saving of one in six results from the use of the "*Wheat Barley*." Good Barley contains two and-a-half per cent. of "Phosphate of Lime," the principal component of all *bones*, Indian bred horses and ponies, are deficient in bone, as compared with the Arab horse, Burmah pony, and Thibet pony, all being fed chiefly on barley. The Indian horse gets barley and gram mixed, but preferably only gram. The results is the high price of *gram*. *Now if* the Government fostered the cultivation of "*wheat barley*," two valuable results would follow, the first being the improvement in bone, of all horses, bred and raised for the mounted branch of the Army, and the second a very considerable saving in the cost of horse food.

The zemindars, or agriculturists interests may now be considered—First, all unsold "*Wheat Barley*," excepting that required for seed, would be available for food—2nd, the corresponding quantity of wheat would be placed in the market for export to London—3rd, a considerable quantity of gram now consumed by horses, would be sent to Europe, and as this might be "*white gram*," the zemindar would realise the difference in money value, which would not be insignificant—4th, with this *wheat barley* to hand, European distillers could produce very large quantities of extra superior whiskey and a glass of hot whiskey punch, would come within the means of the ryot in place of the poisonous 'Mudrack," of the Kullaul. Finally the Excise would be a gainer, and Rs. 24 per dozen and upwards would cease to be paid for imported Scotch and Irish whiskey, whilst an export trade in Indian whiskey would be called into existence, and become permanent."

PINUS LONGIFOLIA.

The Secretary mentioned that he had distributed largely the seed of *Pinus longifolia*, received in June last, from the Superintendent of the Botanic Garden, Saharunpore, and that there was still a good quantity in hand, for which he would suggest early application. This tree, it would be remembered, was brought to the notice of the Society by a Member (Dr. Geo. Henderson) in the early part of the year (*see* proceedings for February) as well worthy of cultivation whether for shade, ornament, fuel, or timber. A list of parties to whom the seed had been distributed was placed on the table, including managers of Tea Gardens and others in various parts of the country.

Letters were submitted—

1. From Secretary, Government of Bengal, on the subject of certain models of Agricultural Appliances from China, Japan and the Philippine Islands.

2. From Baboo Mohesh Chunder Bose, Berhampore, forwarding two instruments to add to the collection of Agricultural Appliances one of iron and another of silver, used for making incision in poppy pods.

3. From the Under-Secretary, Government of India, Agricultural Department, forwarding copy of a correspondence regarding the cultivation of *Ileana luxurians* in the Punjab.

4. From the Secretary, Agricultural Institute, Bijnore, returning thanks for supplies of seeds.

5. From the Deputy Commissioner, Peshawur District, stating in reply to inquiry, that the white gram alluded to in the recent proceedings is cultivated in the Logar Valley and the country generally round Cabul. It is sown in March and ripens in July and August.

6. From the Assistant Commissioner, Hurdui Oude, applying for some of Captain Pogson's seed barley, alluded to in the proceedings for June. Mr. Naber writes—"I am in charge of the Public Gardens, and we are just now trenching some land according to the wishes of the Commissioner, a portion of which has been turned up by experimental plough, in which I should like much to try this barley also in the garden. I see you have been discussing the white gram. I have grown it for several years; but always found both at this place and Pertabghur that it required irrigation to bring the grains to their proper size."

MINERALOGY.

THE Government of Bengal has made a definite offer of three lakhs of rupees for the Bengal Iron Works, and the liquidators propose to put up the property for sale at auction, in one month's time, setting upon it an upset price of three lakhs, and if no bid above that sum is made to accept the offer of the Bengal Government.

CHARCOAL IRON IN INDIA.

ARCHÆOLOGISTS have divided prehistoric times in every country into the ages of stone, bronze, and iron, according to the nature of the implement and weapons found in ancient dwelling-places and tumuli. Dr. Percy, the chief metallurgical authority in England, used to insist that the three ages could not possibly have succeeded one another in the order usually given - the age of iron must have come before that of bronze. It is true that the iron implements now discovered mark a degree of civilization higher, as a rule, than that indicated by bronze remains; but then iron is such a perishable metal, that the earliest weapons and utensils made of it may have long ago disappeared, while those of bronze remain. This opinion, so much at variance with the current theory, Dr. Percy founded on a metallurgical argument—the extreme difficulty of making bronze, a mixture of two metals both very difficult to extract from their ores, and the ease with which malleable iron may be made from ores which occur in abundance nearly everywhere. As a matter of fact, at the present day bronze is only manufactured in the most highly civilized countries of the East and West, whilst every savage living in countries containing the ore (except the Americans) knows how to make excellent iron. From pure oxides, such as occur in many countries, iron can be extracted so readily, that it could hardly miss being accidentally discovered by a savage who had lighted a fire and made use of pieces of the ore as hot stones to boil his dinner.

In India we find the aboriginal populations everywhere expert in the manufacture of iron. In Kumaon and the hills generally, this work is left to the Dums; and in West Bengal and Chota Nagpur to the Aghurias, who, from their ugly features and their habit of working at night over the glowing furnaces, are said to have been the prototypes of the ghouls and ogres of fable. The methods of making iron in India have been often described by officers of the Geological Survey and others. A small clay furnace from 18 inches to three feet high is used, and the fire in it is constantly blown by pairs of bellows, of various construction working alternately and sending the air in by separate pipes or tuyers. Perhaps the commonest kind is the ordinary goat-skin bellows, two of which are worked by a man sitting between them. Charcoal is first filled into the furnace and, then lighted and blown till it forms a glowing, nearly white hot mass; when alternate layers of finely-broken ore and charcoal are placed on the top until as much as can be conveniently worked in the furnace has been added. An opening is made for the slag, or molten oxide combined with the impurities of the ore and fuel, to run out; and then a lump of soft spongy iron mixed with slag is removed and instantly welded into a compact mass. The whole process lasts about six hours. The iron thus obtained is of the softest and toughest description, equal for making horse nails and such purposes, to the best Swedish.

The great drawback to the process is that it is so wasteful both in the matter of ore and fuel. We learn something about the amount of this waste from a sort of inter-provincial report on the native methods of making iron in this country, and on the prospects of the trade in competition with the cheaper English-made iron. The paper is circulated by the Bengal Government; it was printed at the North-Western Provinces Government Press; and though it bears no name either at head or foot, internal evidence shows that it was probably written by an officer of the Punjab Forest Department. It therfore deserves to be called inter-provincial. It seems that, on the average, only about one-third of the total iron in the ore is extracted by the native process, the other two-thirds being lost in the slag; and to make a pound of iron, about 13lbs. of charcoal are required. In the round-about process of making smithy iron employed in England (formation of pigiron, puddling, rolling puddled bars, piling, reheating, and rolling again) only about 20 per cent. of the iron is lost, and the total expenditure of coal or coke—much cheaper kinds of fuel than charcoal—is only about 18lbs. for a pound of iron. But for the superior quality of the native iron, the industry

would, doubtless, for this reason have been swamped long ago by the cheap supplies obtainable from England. Another objection to the native process is that only the very purest ores, carefully washed and sorted by hand, can be employed, because if inferior ore were employed it would be impossible to exclude the earthy matter from the spongy iron. The objection, however, is of little force in India, where labour is so cheap and where, as at Lohara in the Central Provinces, we have entire hills composed of stone which contains 98·6 per cent. of the pure oxide of iron. The objection to the Indian charcoal iron on the score of cost would doubtless disappear if, instead of the native process the English method of employing large blast furnaces producing cast-iron were introduced under proper conditions. The blast-furnace method, though indirect and to some extent wasteful in the matter of fuel, has the great merit that by fusing the iron it effectually frees it from the earthy matters of the ore, and of the ash when coal is used as fuel. None of the new direct methods, after which the Government of the Central Provinces has been striving for some time, can do this. The spongy iron must be melted either in the furnace or in a cast-steel-crucible, or else we must sacrifice more than half the iron to form a fusible slag as in the native process.

There is no reason why iron equal to the best Swedish should not be made out of Indian ores with charcoal fuel, after the Swedish and Russian methods. The cast iron thus produced could be made into the finest Bessemer steel, because the Indian ores are unusually free from the elements sulphur and phosphorus, which, when in large quantity, are fatal to the Bessemer process as usually worked. Pig-iron manufacture by means of charcoal fuel, has just been given up as a failure by the N.-W. P. Government, which for some years carried on a smelting establishment at Dehchauri in Kumaon. Several good reasons are, however, given in the paper abovementioned for this failure. In the first place the furnace was too large to be worked by natives alone; and the pay of the European overseers was too great to be fairly debitable to one furnace, when these men could equally well have looked after several. The chief reason, however, was that half the ore had to be carried 28 miles from Ramgarh on men's heads or on the backs of mules. In Europe the owner of such a furnace would either have constructed a tramway by which to bring the ore from a distance, or he would have tried to work with the ore on the spot. There is plenty of ore at Dehchauri close to the furnace, costing next to nothing to raise; but it was considered too aluminous to work by itself, and therefore the silicious Ramgarh ore was added to it. The writer of the report thinks it a pity that the Dehchauri works were stopped so soon; certainly, before they were stopped, the experiment might have been made of using the ore found at the place, mixed with limestone and sufficient sandstone to make the slag fuse readily. The ore contains 38·3 per cent. of iron; and if 20 per cent. of silicious material were added to it, it would still have as large a percentage of iron as the bulk of English clay ores. A much smaller addition of sandstone would probably have been sufficient.

The manufacture of iron and steel is likely soon to be again revolutionized, as it was not long ago by Bessemer; and the new system will probably prove fatal to the production of charcoal iron in this and other countries. In the Bessemer process excellent cast-steel is made from molten cast-iron in a few minutes; the iron being run into a vessel lined with siliceous materials, and there getting its impurities—carbon, silicon, and manganese—burnt away by a blast of air which is forced through it. At the end of the process, enough pure cast-iron is added to convert the whole mass into steel, which is then poured into a ladle and cast. Steel can be thus made in enormous quantities, for each converting vessel will work off six or eight tons in fifteen minutes. Two impurities, however,—sulphur and phosphorus, of which phosphorus is the more deleterious, as it makes iron or steel brittle when cold,—cannot be removed by Bessemer's process, since white hot iron reduces sulphuric and phosphoric oxides as soon as they are formed by the action of the blast. For making cast-steel by this rapid process, therefore, iron ores as free from sulphur and phosphorus as possible soon came to be in great demand, while the inferior ores have been little used of late years. Recently, Messrs. Thomas and Gilchrist have succeeded in perfecting a process by which the phosphorus, and to a less extent the sulphur may be got rid of, no matter how much the cast-iron may contain. The Bessemer "converter" is lined with magnesian limestone, and the mouth of the vessel above the molten metal is filled with lime. When the phosphorus is oxidised, the oxide at once combines with the lime forming a compound which is not reduced by iron.

The Gilchrist-Thomas process has already come into extensive use on the Continent, where iron-masters are less conservative than in England; but, before long we may expect to see excellent cast-steel made in England from the most inferior ore, and then it will be all over with the charcoal iron industry, except in the most remote countries of the world. India may yet rank, however, as one of the great iron-producing countries if either Government or that private enterprise which is so favourably spoken of now-a-days, would turn its attention seriously to the making of iron by means of Indian coal. There is far more wealth in the iron and coal deposits of the Central Provinces and Bengal than in all the gold fields of the Wynaad.—*Pioneer.*

AURIFEROUS REEFS ON THE NILGIRIES.

THE success of the prospectors of gold mines in Mysore and the Wynaad, and the growing belief that some of the companies already formed to work the "fields" will do well, have directed close attention to the character of the formation of the Nilgiri Hills, with the result that some gentlemen, who are probably not quite disinterested, have arrived at the conclusion, that whatever may be the fate of the industry of gold mining elsewhere, it may be undertaken with great confidence of success in Kotagiri, and possibly also in Keity valley. A few years ago, some Australians passing through the Nilgiri district, noticed the remarkable resemblance which the surroundings of Kotagiri bore to those of Ballarat, and other gold fields in Australia; but it was reserved for Messrs. Sherman, Griffiths, and Mackenzie, to make a careful investigation of the locality, with the result that their expectations of the presence of gold have been fully realised. A number of reefs have been discovered; and have been examined by Mr. Groves and other mining engineers, who have given it as their opinion, that the district is peculiarly rich in auriferous reefs. After having made careful assays of the stone which he himself had blasted from the reef, Mr. Grove drew up a very favorable report of the prospects of the field, and expressed his belief that one of the reefs would give about one and three-quarter ounces of gold, and sixty-two ounces of silver, to every ton of stone. The reefs have been laid bare in parts to a depth of over fifteen feet, but nothing beyond preliminary operations has been yet done. Only five reefs have been examined on the property, which contains about from seven hundred to a thousand acres, and these are found to run up the hill to the north of the valley. They vary greatly in thickness, and in the quality of the stone. One reef near the bed of the stream, is from forty to fifty feet in breadth; another, about a quarter of a mile distant, to the north is about ten feet broad, and is almost in the bed of one of the large streams that run down the mountains. From this stream rich alluvial deposits have been taken. A third reef is situated some hundred feet up the hill, towards Kotagiri, and it is believed to be a continuation of number two, already mentioned. This third reef is not far distant from a rapid stream which runs on the other side of the hill on which it is, and the quartz taken from it, could be run over the crest of the hill to the stream on the other side where a second reduction establishment could be formed. The quartz is white, but a good deal stained with a reddish tinge, and is charged largely with pyrites, in which iron, arsenic, copper, silver, and gold, appear to be combined.

Situated at an elevation of about 7,000 ft. above sea level, Kotagiri is well adapted for mining operations; and possesses some advantages which none of the other Indian gold fields can boast of. Taking up a position about two miles west of Kotagiri, on the crest of one of the ridges of the surrounding mountains, and in the centre of what is regarded as the auriferous district, the land lies mapped out at one's feet. Southwards lies the richest part of the valley, at the depth of some hundreds of feet; and this valley is seen to be bounded by lofty and picturesque mountains, except to the east, where the hills gradually slope towards the plains, until a large high bluff standing out clearly against the far distant blue plains is reached. Still looking southwards, the huge hills forming the Kunda range which intervenes between Kotagiri and Coonoor, tower up; and on their steep sides, appear, here and there, the estates and bungalows of coffee-planters. To the north are Down-like hills sweeping away in graceful undulations. Four different streams running down the mountain sides, unite a little above the narrowest part of the valley, and the united body of water passes through it. It is believed that sufficient water power to work a 20 head stamp can be safely calculated upon from year's end to year's end; and that by constructing a large reservoir for the storage of the monsoon rain, as much more hydraulic power as can possibly be desired, may be easily and economically secured. Local labour is at present abundant; and to the Burghers, if not perhaps to the coffee planters, in the neighbourhood, the establishment of a new industry would be welcome. The climate is salubrious, and the temperature is usually 3 to 5 degrees warmer than that of Ootacamund. The locality is thus well suited for the permanent residence of Europeans with their families; and visions of cosy cottages in the midst of flower and vegetable gardens with some of the features of English villages around them, are easily conjured up as one surveys the scene which now wears so placid an aspect. The valley is connected by a road, twelve miles long, with Coonoor; and it has a road of its own to Mettupolliam at the eastern foot of the Blue Mountains. These roads meet the present demands upon them fairly well; but they would have to be taken in hand, and their bridges considerably strengthened, to allow of their being used for the transport of quartz crushing and other heavy machinery. The Kolar gold mines have a great "pull" over the other gold mines in Southern India, by reason of their proximity to the railway and the sea. Against this advantage may fairly be set the disadvantage connected with their inability to use water in lieu of steam power; but as fuel seems likely to continue abundant, this drawback may be overcome. Fuel is not one of the strong points of the Neilgherries, as every one who has resided at Ootacamund or Coonoor, knows to his or her cost; and the proved existence of an abundant and perennial water-supply is likely

to have a good deal to do with the development of the auriferous resources of Kotagiri.

Hope tells a flattering tale to the gentlemen who have been looking beneath the surface of their property; and this tale is borne out by specimens. If—it is disagreeable to have to use this suspicious little word—if Kotagiri should prove to be a Ballarat even on a comparatively small scale a great stride may soon be made towards the solution of that painful question connected with "poor whites," which has proved too hard a nut for several successive Governments of India to crack. The Wynaad gold fields are to some extent handicapped by the Wynaad fever; whereas with ordinary care European and Eurasian settlers on the Neilgiris need fear no fever. But it is hardly worth while to anticipate just at present what may be the consequences of the discovery of payable quartz in the Neilgiris, or elsewhere in Southern India, for the British public, who are supplying the bulk of the funds for prospecting, are growing restless for want of results. They are being assured by specialists that it is idle to demand results so soon; but having to a great extent, rushed into the enterprise with their eyes shut they are not too ready to attend to those who urge them to be patient. It is well known that the prospectuses of a number of new Indian Gold Mining Companies are cut and dried, and are only waiting the announcement of good crushings from Kolar or the Wynaad, or, better still, from both, to be published. Among them we are not unlikely to find a scheme for developing the untold wealth of the Kotagiri valley.—*Madras Mail.*

THE DIAMONDS, COAL, AND GOLD OF INDIA.

MR. BALL of the Geological Survey of India, has compiled a little work entitled "The Diamonds, Coal, and Gold of India, their mode of occurrence and distribution." He does not profess to give the world anything that is new on these subjects, but he has been led to issue his present book by the "growing spirit of inquiry in reference to Indian mineral deposits." Three of the papers in this volume have been previously published. With regard to diamonds, the information he gives us may be looked upon as supplementary to that found in Mr. Emanuel's valuable book on precious stones, &c. They are found in India in "three extensive tracts, widely separated from one another, in which the diamond has been sought for from the earliest periods of recorded history." In this presidency diamond mines have been, or are, met with in Cuddapah, Kurnool, Kistna, and Godaveri districts. Another region where they are found is a portion of the area between the Mahanadi and the Godavery. The third great diamond tract is in Bundlecund. In 1869, we are told a Mr. Richardson, of Madras, applied to the Collector of the Cuddapah to work the mine paying a rent of one hundred rupees. The result was not favourable, although, Mr. Ball adds, there "are accounts of two diamonds having formerly come out of this field which were eventually sold for Rs. 5,000 and 3,000 each." In the Kurnool district, there are some eleven localities where, according to Mr. King, diamonds may be, or have been, found. The Nawab of Kurnool leases out certain diamond mines for Rs. 750 a year; so we naturally draw the inference that they are not very valuable. Diamonds are sought for in the Mahanuddy, in the bed of which stream are also to be found pebbles of beryl, topaz, carbuncle, amethyst, cornelian, and clear quartz. The following description of the method of working will give our readers a fair idea of Mr. Ball's style of writing:—"In the centre of the Mahanuddy, near Jhunan, there is an island called Hira Khund, which is about four miles long, and for that distance separates the waters of the river into two channels. In each year, about the beginning of March or even later, when other work was slack and the level of the water was approaching its lowest, a large number of people—according to some of my informants as many as 5,000—assembled and raised an embankment across the mouth of the northern channel, its share of water being thus deflected into the southern. In the stagnant pools left in the former sufficient water remained to enable the washers to wash the gravel accumulated between the rocks in their rude wooden trays and cradles. Upon women seems to have fallen the chief burden of the actual washing, while the men collected the stuff. The implements employed and the method of washing were similar to those commonly adopted in gold-washing, save only that the finer gravel was not thrown away until it had been thoroughly searched for diamonds—at least I was given so to understand, but Tavernier's account of this part of the process is probably correct. Whatever gold was found became the property of the washer, as already stated. Those who were so fortunate as to find a valuable stone were rewarded by being given a village." We have not space to refer to all the districts referred to by Mr. Ball. He tells us that none of the attempt made by Europeans to mine for diamonds has turned out successful. He does not suppose that there has been any real exhaustion of the localities where mining is possible, but owing "to the facilities for peculation in consequence of the readiness with which a gem may be conveyed," it is doubtful whether Europeans can make the speculation pay. Mr. King says that for those content with a slowly paying occupation and a hard life involving close, personal supervision of the workers, it would pay, provided such persons possessed capital sufficient to last them some years.

We are inclined to believe that India will receive much more money for her "black diamonds" than for her white ones. India has coal in districts measuring 35,000 square miles, as will be seen by the following list, which Mr. Ball says was drawn up by his colleague, Mr. Hughes:—

Godaveri and affluents	...	...	...	11,000	square miles
Sone	...	...	...	8,000	"
Sirguja and Orissa	...	...	...	4,500	"
Assam	...	...	...	3,000	"
Nerbuda and affluents	...	...	...	3,500	"
Damuda	...	...	...	2,000	"
Rajmahal area	...	...	...	700	"
Unsurveyed	...	...	...	2,700	"
				35,000	"

The outturn of coal in India is annually increasing, but whether Indian coal will ever entirely supplant English coal is somewhat doubtful. As railways increase and our interval communications are improved, the demand for Indian coal will doubtless grow. Probably most readers of Mr. Ball's book will be tempted to turn in the first instance to the chapter on gold. They will be disappointed if they expect to find there any thing new regarding this absorbing topic, so far as South India is concerned. We are told what Mr. Smyth says, what Dr. Barwell says, and so forth, and there are extracts from William Abbot's monthly price list, and from the *Times of Mail*, but we did not read the book for the purpose of being told what we had previously read, and consequently we must say that we are greatly disappointed with Mr. Ball's book. It is merely a compilation from various Government records that are accessible to everyone. Of what value can the following opinion be to any one:—"In the neighbourhood of Chaibassa the chief town of Singhbhoom, I have been especially struck with the auriferous aspect of the rocks. The earthy slates and shells with magnesian schists, and numerous small quartz reefs, are precisely the rocks which, judging from all experience, *ought* to yield gold." Had Mr. Ball wished it, he might have made his book really valuable and useful. There is a mass of information in various official records that he had available for his purpose. A man with his knowledge and opportunities ought to have produced a "standard work"—one to which people would refer during the next quarter of a century. As it is, we have got little more than what may be described as a "catch-penny" book,—one written to sell.—*Madras Times*.

THE SALT CAVES AND MINES IN THE PERSIAN GULF.

FROM a recent report by Assistant Surgeon Abder Rahem, it appears that in that part of the Persian Gulf lying between latitude 26° 10' and 27° 10' N. and longitude 53° 50' and 56° 30' E. is an extensive area, abounding in a large deposit of salt, which crops out at various places on the earth's surface, rising up into ranges of rocks of no little magnitude. The following are the principal places from which salt is obtained in this area:—Kowin, on Kishm Island, Hormuz, Larak, Pohal, near Khamir, Sir-bu-Na'air, Jabal Bostana, and Hameran, on the Persian coast. The salt-bearing rocks are of a reddish colour, from red ochre, varying from earthy consistence to stony hardness, which covers the salt deposit, and is more or less mixed with it, imparting to it a red tint. The ochre is associated, to a small extent, with specular iron ore. The association of the ochre with salt is so constant in the salt area that the existence of the former is almost a sure indication of the presence of the latter. About 16 miles from the Bassidore Station in a south-easterly direction, and three miles from the village of Kowin, on the island of Kishm, is a range of rocks bordering on the sea, and consisting very largely of rock salt covered in some parts by red ochre, while in others large masses of salt of stony hardness and reddish tint compose the surface and mass of this rock, giving it the appearance of a structure made of red bricks and mortar. A salt cave is situated in the western end of the range of rocks, and besides this there are several other places where briny water issues, and collecting in hollow ground close to these rocks, deposits beautiful crystalline masses of salt by spontaneous evaporation. It is stated that some forty years ago, the salt was largely procured by this method; numerous shallow pits were excavated, where, as the brine evaporated, it deposited salt, which was then collected for commercial purposes; but since the natives commenced to quarry the salt, the pits were neglected, as the process was tedious, and the salt obtained, little in quantity, and not good in quality for commercial purposes; at the present time, however, the streams of brine and some of the pits still exist, and yield a certain quantity of salt for home consumption. The working of these salt mines during the past thirty or forty years has given rise to large caverns in the bowels of the rock. In almost all these caves, from the trickling of the brine, stalactites of various shape and magnitude are formed, yielding snow-white masses of salt of saccharoid description. The salt is found in four principal forms. First, pure white masses, easily reduced to granules; second, red masses of stony hardness; third, saccharoid masses, from trikling of brine; and fourth, translucent and transparent masses of cubical forms. The granular form is the most valuable, and is generally of a pure white colour; the red hard blocks are principally used by the natives for salting fish. The salt is dug out by means of crowbars, and it is by no means uncommon during the working of the mines for people to be buried alive from earth-falls. The mines which yield the present salt are situated about two miles from the seashore, and the path leading to them winding between the rocks is

very difficult for the camels to traverse. The salt is brought on the beach by the camels, costing about 4s. for every *bahar*, or ton and-a-half, and, calculating the customs charges at 1s. 6d., and the cost of quarrying at 5s., the total cost of the salt on the beach would be about 10s. 6d. per ton and a-half. Recently salt of an excellent quality was quarried from the rocks, about 100 yards only from the seashore, thus saving the cost of carriage to the miners. The salt mines at Hameran are also extensive. They are situated about four miles from the seashore, and the salt is found in beds of about 4 ft. thick, with intervening layers of earthy material. The salt beds are hard in consistence, and broken by means of gunpowder, the masses being subsequently reduced to granuels by wooden and iron mallets. Some of the specimens found were of a pale greenish colour, from an earth of that tint. This earth exists in isolated deposits and mounds, varying from earthy softness to stony hardness; the green tint being produced by the influence of manganese. The quarrying expenses at these mines are about 5s. each ton and-a-half, camel hire amounting to about 4s. 6d., and boat hire to Lingah being about 8s. Large quantities of salt are exported by native boats to Muscat, whence it is carried by merchant vessels to Bengal, Zanzibar, Mauritius, Batavia, &c. There is an average annual export of from 25,000 to 30,000 tons of salt from these mines, the best quality coming from the Kishm Island and Sir-bu-Nufair. The price of salt at Linga varies from 4 to 5 dollars, while at Muscat it is from 5 to 6 dollars per *bahar*, or ton and-a-half. There are, in addition to these caves and mines, certain springs in the rocks close to the village of Salakh, near Henjam, the waters of which are warm, and charged with salt, yielding naphtha of a reddish colour. It is highly combustible, burning with thick smoke. The natives use it for purposes of light, and also use it locally for rheumatic complaints.

DEEP BORING FOR GOLD.

THE diamond-drill has made a conspicuous success. We recently reported that in the Crown Cross United mine at Stawell, the diamond-drill was set to work at a depth of 1,322 feet, and on boring 375 feet further had pierced a reef of about 10 feet in thickness. The core has been tested, and is found to contain gold at the rate of 17dwt. 3grs. per ton, a prospect with which the company is so satisfied that it purposes at once beginning to sink for the reef. This work will occupy a year, and will cost about £1,000. The discovery is entirely due to the new and valuable instrument of which miners have recently secured the use. Without it, it is quite possible that the company would never have incurred the expenditure necessary to sink a shaft. This is not the only, though it is the most prominent instance of the usefulness of the drill as an instrument for prospecting. It is not long since that its use in a claim at Hepburn led to discoveries which improved the quotable nature of the claim to the extent of £10,000. At Stawell, we learn that the discovery in the Crown Cross United mine of a paying reef at a depth of 1,700ft. has infused a new spirit of enterprise into mining work. The discovery in itself of paying quartz at this great depth is of vast importance as giving an enormous extension to the area of our known workable ground, and it immensely enlarges our views of the permanence of gold-mining in the colony. But the great point of interest is that the discovery was made by means of an instrument which reduces the cost of underground exploration in a very great degree. It is quite natural that the utility of the instrument should specially strike the public mind when it leads to a positive discovery. But it is easy to see that it is equally useful when its use indicates at a small outlay the inutility of expending money in any certain direction. We have to count not only what it gives, but also what it saves. It is satisfactory to see the rapidity and enterprise with which companies are adopting these useful adjuncts to the art of the miner. The general use of the drill will give greater certainty and precision to mining work, and while it will often, doubtless, lead to eminently satisfactory discoveries, it will also tend to materially improve mining as a sphere of investment.—*Australasia.*

THE GARDEN.

WE may observe once more that one little islet of the Bristol Channel alone preserves the red peony. Holyhead Island has half-a-dozen rare species. The Jersey centaury, Pelisser's linaria, and several other southern flowers, have died out everywhere save in the Channel Islands. Sicily shares with them in the sand bird's foot. The Irish Arran and other Irish islands have many peculiar species; and a few southern types even reach. But and the western Highlands; for, as everyone knows, Rothesay has a climate almost as warm as Torquay. So, too with the peninsulas. The Lizard, with the most equable temperature on the English coast, is a perfect mine of wealth to the botanist. It has three peculiar southern clovers, and lots of other rarities. Penzance, at the very heart of Cornwall, has five or six peculiarities. The position of Kerry gives it a climate like that of Finisterre, with the appropriate flora. Wild Madder belongs only to a few headlands of Pembrokeshire, the Damnonian peninsula, and the south-west of Ireland. Torquay, on the promontory of Hope's Nose, shares a southern buplever with the Channel Islands. Babbicombe has a species almost to itself. Corfe Castle, in the so-called Isle of Purbeck in Dorset, divides a Spanish heather with Cornwall and the West of Ireland. One kind of restharrow, after getting up from the Pyrenees as far as the Channel Islands, then positively takes a second spring to the Mull of Galloway. As to the number of Mediterranean plants which are found in Britain only in Devon and Cornwall, or in Kerry and Connemara, or in both, I spare you the recital of them. Even the more inland and moorland types, which each survive on one high common alone, answer to the same law; for south-western slopes. Thus, the chedder pink grows in a single basking hollow heated by radiation from two great walls of limestone rock upon the western flanks of Mendip; the purple lobelia loiters on a bright upland near the warm valley of the Devonshire Axe; the white sedum struggles on upon the edge of Malvern; and my hairy woodspurge here battles hard for life on Claverton Down, close to the steaming basin of the old Roman Thermæ at Bath.

NOTES ON ROSES.

EVERY one who is at all conversant with the character of our exhibitions for some years past, must have noticed the increased and increasing numbers of roses of this beautiful class. Do not be afraid, good reader—I am not about to ride off in an estate, frenzy upon their value and beauty; no Amadis of Gaul, descanting of the beauty of his fair Elisena—no, not even Don Quixote himself, when describing his Dulcinea, has used more extravagant language, or written more sentimental nonsense, than have some exceptional lovers of the Tea Rose. But there is without doubt an elegance and refinement, and a delicacy of colouring about them which is possessed by no other class of roses; they are essentially the ladies of the court of the queen of flowers, their delicate fragrance being a fitting pendant to the colour. Then again their permanence of bloom is a great feature in their favour; a bloom of the most exquisite hybrid perpetual a few hours after it has been cut has lost its beauty, the colour has flown, and it is only a shadow of its former self; not so the Tea Rose; at least, with many, indeed, most of them, there is such thickness of petal, such firmness of texture, that they retain their beauty for days; then the colours, being of a character less affected by light, are more enduring, and I have known instances where individual blooms have done duty at two shows some days apart.

These characters are not shared in even by their closely allied neighbours, the Noisettes, Maréchal Niel, that grand yellow rose and universal favourite, cannot be said to be a refined rose; while Gloire de Dijon, grand old flower as it is, or Solfatorre, or Madame Berard, cannot claim the same distinction. Several causes have, I think contributed to the great increase of the growth, and consequently of the exhibition of the Tea Rose, but the general reason is, without contradiction, the introduction of the seedling Brier, by Mr. George Prince of Oxford. I say, the introduction, because although it may have been used by others, and especially by the French growers, for the same purpose, yet he was the first who boldly, and as some thought rashly, entered upon it. The Brier had ever been considered the most appropriate stock on which to work them. The Manetti did not answer with a good many varieties, its vigour was too great; and many a novice who had watched the vigorous growth of his plants and wondered why they did not bloom has been disagreeably disenchanted in finding that his poor Tea Rose had been smothered by its foster mother.

Now the Brier seems to possess just the vigour that is required, and the seedling Brier possesses this advantage over the old form of growing on the standard or half-standard—that it can be budded low down, and consequently protected, whereas, in such winters as the two last those on the wild Dog succumbed to the frost. The tens of thousands of this class sold by Mr. Prince and the demand made on other growers for sale to supply them show how much the rose-growing public has appreciated this step. Another evidence of this increase of growth is seen in the fact that it is not now uncommon to see stands of twenty-four, eighteen, and twelve teas, whereas formerly twelves and sixes used to be the utmost that was attempted.

At the same time some of the old ideas on the subject of their culture (owing, indeed, in a good measure to the new method of growing on the seedling Brier) have been abandoned. We are told that they would not bear the knife well, and therefore in pruning all were so pruned simply to shorten the tips. Now this is all altered; it is generally admitted now that they will bear the knife as well as the hybrid perpetuals, and may be cut quite as hard. The last two winters have indeed taught us many a lesson, and this has been one of them. Tea roses have been killed down to the snow line or the mulching line, and all the frozen or half-frozen wood had to be cut away, but they almost immediately started into fresh growth, and although a little later this was no evil, as they often came in so early as to have their blooms ripened. With this, then, all necessity for putting fern amongst the branches for protection has ceased, and I would, even if the winter were mild, be inclined to cut them as hard back as I would a rose of any other class. Probably in the northern parts of our island, and in the Midland Counties, exception might be taken to these statements, for I believe growers have been discouraged from making the attempt, owing to their failure under the old conditions; but I am none the less inclined to think they too, if they were to grow on the seedling Brier, and mulch heavily, say to the depth of 6 or 8 inches, would find that they could manage their cultivation without their having recourse to glass or taking up the plants and laying them in by the heels.

Into the very vexed question of hybrid teas I must not at present enter; the present year's exhibitions will be conclusive as to their value in this respect, and, also as to garden roses; the French have sent us some over, and Mr. Bennett has added largely to the list. They are now both on their trial, and the result a few weeks will determine. But I think that few persons will view with regret the rule of the National Rose Society which excludes them from being shown amongst the pure bred teas and Noisettes; the introduction of foreign blood has not improved them in those two points, for which I contend the Tea Rose is pre-eminent—delicacy of colouring and refinement of flower.—*Wild Rose.*

HYDRANGEAS.

THERE are few species of this family of plants, but such as there are, are among the most beautiful of decoration plants. Every one is familiar with the common hydrangea, so common that it has with cottagers all over the country monopolized the family name, as it were, without the use of any specific designation whatever. It is the hydrangea hortense, the hydrangea of the garden of the botanists; but with greater fitness it might be called the cottage hydrange, as it is decidedly more generally cultivated in cottage windows than in gardens. Of late years, however, nurserymen and florists have given more attention to the culture of this plant than formerly. London florists grow it by the thousand for the supply of Covent Garden Market. They grow it in small pots, 5 or 6 inches in diameter, in rich soil, from cuttings that have been rooted in small thumb-pots; and by feeding the plants well with liquid manure, after they have filled the larger pots with roots, they obtain splendid foliage and a magnificent head of bloom to each plant. To follow up this system well, the amateur would require to be provided with at least a small frame in which to strike his cuttings and grow them. The cuttings should be taken from the growing points of the stems of an old plant, the strongest only being taken, and each cutting should have at least three pairs of fine leaves above the pot or soil, and be inserted to the depth of one joint in the soil, a clean cut being made across immediately under this joint, removing all of the stem that may be attached below before insertion into the soil. The cuttings must never be allowed to become dry nor be exposed to strong sunlight till they are rooted, else they will lose their foliage, and, though they may even root after the leaves have dropped, they are weakened and disfigured by the loss. As soon as they are well rooted they should be shifted into their flowering pots, either 5 or 6 inches diameter, according to the apparent strength and promise of the individual cuttings. They should then be gradually inured to air, which, by and by, they will bear in such abundance as the temperature out of doors may suggest. If they are rooted in early spring (and they may be done at any season except the dead of winter, if suitable cuttings can be obtained) or late autumn, it will be more necessary to give careful heed to this point than if they are done any time between those two periods in the summer half. The plant is very hardy, but is easily weakened when growing freely by sudden cold approaching to frost, or by frosty wind being admitted to it. The compost should be made up of rich materials, chiefly strong but friable loam, abounding in vegetable fibre, and further enriched by the addition of horse droppings, which should be put through a sweetening process before being used. In fact, the compost should be made before being required for three months; the horse droppings being used in the proportion of about one-fourth of the loam. The plants must be kept growing freely till they have quite filled the pots with roots, when they should be well exposed to sun and air, and kept supplied with water in abundance, each watering with pure water being alternated with manure water from cow manure or good guano, the latter in the proportion of about 4 ounces to the gallon, made up some hours before being used, in order to allow of it becoming clear, when it should be run off into watering-pots for use. A little iron-filings put into the liquid will give that peculiar blue tint to the flowers which is so much admired in hydrangeas.

Other species of hydrangea there are, but none so useful for general decoration, and for keeping up a successional supply for the conservatory or green-house as hortense; it is the queen of the genus for that purpose. The next in importance, simply because it can be treated in the same way, is *H. Japonica*, the most common form of which in gardens is that with silvery variegated leaves. The chief difference between the two species rests in the flowers, which in hortense are wholly monstrous, that is, each flower is accompanied by bracts or floral leaves, which are popularly regarded as the flowers, which, however, really are only the small body in the centre of the bracts of pink or white or blue floral leaves, which give character to the floral cyme or head of bloom. In *japonica* the flowers in the outer branches of the cyme are accompanied by this bract, while the central flowers are naked, thus reducing the decorative importance of the plant somewhat. Nevertheless, it is a beautiful plant, and well worth growing for variety's sake when more than a few are wanted. As before said, it will respond to the same treatment as hortense, and deserves to be more frequently grown in the same way than it is.

The next most important species for decorative purposes is one of comparatively recent introduction. *H. paniculata grandiflora*. It is more shrubby than either of the two foregoing, which are also less hardy. In fact the present subject will endure our hardest winters out of doors, as has been proved in many parts of the country during the last and immediately preceding exceptionally severe winters. It survived last winter in the open air, and is now flowering or rather showing its panicles of flowers bravely. It is a grand acquisition to our list of hardy shrubs, and is no less valuable for pot culture for conservatory decoration. The flowers are creamy while produced in elongated panicles, forming most graceful objects in summer and autumn in the green-house or open air.—*N. B. Agriculturist.*

CULTIVATION OF VIOLETS UNDER GLASS.

THE present will be a good time to pot up the necessary number of plants for yielding a good supply of these ever acceptable and much sought after deliciously-scented flowers through the autumn, winter, and spring months. And the fact of their being had out of season—a circumstance which, like all garden produce, greatly enhances their value—renders them all the more acceptable. In order to attain success in this respect the plants should have been previously prepared for this purpose by thinning out the runners (which those planted out individually in April or May send out freely when they commence to grow) to four or five of the strongest, and those having the most solid crowns, and the points pinched out, and all the other runners cut out as soon as they appear, the object in view being to concentrate the sap into those left, from whence eventually the flowers proceed.

In the event of the abovementioned details not having been attended to, as described at the proper time, they should be observed when the plants are being potted, which should be in an admixture of good friable loam, decomposed cow-dung, and leaf-soil, with sufficient sand to keep the whole porous. If the plants are potted into three sized pots, viz., 24's, 32's, and 48's—they will come in very useful for the embellishment of the conservatory, &c. When the plants are being potted, let the young crowns be placed regularly round the edge of the pots, and the soil pressed firmly together and watered. The plants should then be taken to the frames allotted to them, and the pots plunged to the rim in sawdust. The frames should occupy a warm corner under a south wall, and be fixed in such a way as to allow of bottom-heat being applied when necessary by means of fermenting dung and leaves, and so that the latter are not exposed to view, and therefore not objectionable in that respect. This is easily managed by measuring the length and breadth of the frame or frames, intended for the growth of the violet plants, and then taking out a trench a couple of feet deep, and a few inches narrow and shorter than the frames and having some oak posts 7 feet long driven into the ground about 3 feet 3 inches, and about 5 feet apart, the exact width and length of which should be identical with those of the frames. On those posts, which should be level, fix an oak plate, about 2½ inches deep and 8 inches wide, for the frames to rest upon, and a piece of inch board projecting an inch above the plate or frame-sill, nailed to the latter at the sides and ends, to keep the frames in position. The frame-work should be bound together by means of cross-pieces fastened to the upright posts about 3 inches below the bottom of the frames, to allow of a bottom of straight-edged slabs being made for the latter, which should then have sufficient sawdust put into them to raise the plants to within a few inches of the glass when plunged to the rims of the pots. This done, the sides and ends of the skeleton frame should be boarded up, and shutters made to fit between the posts in the back, and fastened by means of wooden nuts fixed to the former, so that they can be easily removed and replaced when necessary.

In the event of bright sunshine at the time the plants are potted shade them for a few days until the roots have taken hold of the soil, after which subject them to the full rays of the sun, and as the plants become well established in the pots by filling the latter with roots, weak liquid manure should be given them occasionally, which will enable them to throw up and develope finer blooms, and in greater profusion.

On bright days the sashes should be taken off the frames for a few hours to allow of the foliage getting dry, as also to maintain the plants (which should not be coddled) in a sturdy condition; and with this object in view they should be ventilated freely on all favourable occasions. On the approach of winter provision should be made for excluding frost from the interior of the frames, as well as conserving the heat therein that may have been imparted by the sun's rays or fermenting material underneath; and for this purpose it will be advisable to protect the ends and side of the frame and framework with a wall of dry fern, built up as follows, *viz.*, commence at one end of the frame, or range of frames, as the case may be, and make a row of holes in the gravel about 6 inches deep, 1 foot apart, and 9 inches from the base of the framework, and into each of those holes put a stout and pliable bean-stick sufficiently long to reach to within a few inches of the sashes; then pack the space between the sticks and the woodwork with layers of dry fern up to the top of the former, which should then be securely tied with strong string to a row of screws previously put in the frame within a couple of inches of the top for that purpose, and the same distance apart as the sticks. This done, the loose projecting pieces of fern should be trimmed with a pair of shears; thus completing a neat and effectual side and end protection to the frame from frost, which, together with a covering of fern and mats on the sashes at night during frosty weather will be sufficient protection for the Violet plants.

Violets may also be grown and flowered satisfactorily planted out in frames within a few inches of the glass, in about 7 inches of soil, placed on a hotbed made of three parts leaves and one of stable-dung (including the horse-droppings), and built upon half-a-dozen or so of faggots, to admit of drainage to the bed. But better still, and more satisfactory in the results, a hot-water pit, in which the floral results in quantity and quality are more in the hand of the cultivator.

In conclusion, I may remark that there is no flower that pays better for a little extra care and trouble in the cultivation than the Violet, of which the Neapolitan, Marie Louise, Belle de Chatenay, and The Czar, are the best to grow—especially the two first named varieties; but Belle de Chatenay (double white), and The Czar (dark blue), give variety of colour in addition to sweetness.

It would appear from Tennyson's lines—

> "Thick by ashen roots the Violet grows"—

that it was a shade-loving plant, and flourished especially under the shadow of the ash. This, however, is not the case, as conclusively proved by the profusion of flowers supplied by the Neapolitan and other varieties, which have been planted under sunny walls for supplementing the supplies from those grown under glass in the spring.

Although the Violet has always been a favourite flower in England, there is very little popular tradition connected with it. As an emblem of constancy it has been esteemed in France from a very early period; and this signification may perhaps have had something to do with its adoption by the expectant Buonapartists. And it is stated to have been the prize bestowed upon the troubadour in olden times, and to have been subsequently replaced by its representative in gold. A golden Violet was the prize instituted by Clemens Isaure at the floral games established at Toulouse early in the fourteenth century, which have been kept up with occasional interruptions, to the present day. Yet further back Athens was noted for its love of Violets, and the term "Violet-crownd Athens" is said to occur more than once in classical authors. And though the Violet is not mentioned in Holy Writ, its odour is spoken of in the Koran as "excellent above all other odours; it is as warmth in winter, and coolness in midsummer."

Byron, in his poem, "Napoleon's Farewell to France," makes the following allusion to the Violet:

> "Farewell to the France; but when liberty rallies
> Once more in thy regions, remember me then;
> The Violet shall grow in the depth of thy valleys,
> Though withered, thy tears will unfold it again."

We are told that when Buonaparte was finally conveyed to St. Helena that he gave a Violet to an English naval officer who accompanied him—an intimation, it may be, of his hope (which was never realised) of a speedy return. The revival, in a greater force than ever, in connection with the late Emperor, as manifested at his funeral, and at the mausoleum at Chislehurst, which is sometimes nearly hidden by Violets, is, no doubt, chiefly due to tradition. Its popularity, however, was, says Mr. James Britten, probably enhanced by an incident which happened at the time the late Emperor escaped from the fortress of Ham. A packet of Violet plants having arrived by diligence, the keeper was directed by Dr. Conneau to plant them in pots, and while his attention was thus occupied the escape was effected.

It is stated that the annual sale of Violets in Paris exceeds 6,000,000 bunches, realising a sum of more than 577,000 fr.—*H. W. Ward, Longford Castle Gardens, Salisbury.*

DENDROBIUM FORMOSUM.

OF all the splendid Dendrobes that have their habitat in the jungles of the hills of Eastern India, I think nothing can compare to the plant whose name heads this paper, and yet so little attention has been paid to it that it has been almost totally neglected both in India and Europe. Reputed usually as a Burmese orchid, it is common enough in the lower ranges of the Jaintia and North Cachar Hills, being generally found at an elevation of from twelve hundred to two thousand feet. Its foliage when kept clean, render the plant attractive enough, even when the sweetly scented-lilly-like flower is not out. It is a pure epidendrum, and when in full vigor attains a growth of about eighteen inches in height. The stems are jointed at about every two inches, are longitudinally corrugated and generally covered with short bristles, the strap-like leaves springing from either side of the joints. The flower (which makes its appearance in April and May and again occasionally in September) is produced from the apex of the stems. It measures about four inches across the sepals and petals are pure waxy white; the tip the same, but stained at the bottom with canary yellow. If care and cleanliness are attended to, *D. Formosum* will yield a blossom from each stem, and when in full bloom the effect is very beautiful, the delicate scent diffused, with the chaste appearance of the flowers combined with the dense fleshy foliage make up a truly charming picture.

There are two varieties of this orchid, or at least botanists assert that there are, but I cannot say I have been able to distinguish any difference except from the conditions of growth. *D. Formosum gigantium* is but I believe, the plant when it gets fair play, high up on the *bonak* tree on which it is usually found, for I have invariably found the specimens some forty feet from the ground yield better flower than those obtainable lower down. The plant requires 300 inches of water yearly and exposure only to the north-east sun. It is particularly liable to the attack of the large black ant from the quantity of saccharine matter contained in the stems, and from this pest it is necessary to guard it, which in an orchid can easily be accomplished by rolling a grummet of jute round the suspender and smearing the same with kerosine, which presents an effectual bar to all parasitical intruders. This orchid presents one of, if not the very best medium we have for hybridising, and from the robust nature of the lip and almost certainty of the pod forming, nearly any combination of variety in colour might be obtained. Crossed with *Arundina* we should have a flower rivalling in beauty the loveliest of the Amazonian Lælias, but the immense variety of the impregnating pollen available when the plant is in bloom will of itself suggest to orchid-growers the proper selection. I have this suggestion to make with regard to impregnations. Instead of using the knife, except in the first instance of collecting the impregnating pollen, I think it more advisable to collect the latter in a quill, and gently blowing it into and underneath the stamen. When it is understood that in all hybridising we are endeavouring to imitate the gentle action of the legs and antennæ of the bee, and other natural hybridisers, we cannot be over careful in avoiding all roughness. The hybridising of orchids can only be carried out with time and patience, so that none but such as intend devoting those qualifications to the object had better attempt it, but to such who care to do so, I may mention that a hybridised Cymbidium sold in London in April last for 140 guineas, and a similar result is certain to attend on all successful efforts at hybridising, albeit the hybrid will not be ready for exhibition until two years from impregnation. This assertion may be disheartening to many, but it is better to out with the truth at once lest some might be misled. I myself took six years to get a hybrid between *V. cærulea* and *Plane maculata*, and then only partially was successful. The most energetic orchid-grower in your town, Mr. Lynam I believe, has not yet succeeded in raising a true hybrid; but if he will adopt the quill in preference to the knife, I think I can promise him a victory. If orchid-growers would take *D. Formosum* as their standard, I think we could in Calcutta rival the celebrity attained in England by that veteran hybridiser, Mr. Dominy, whose scientific success is the envy of the leading botanist here. *D. Formosum* is best grown on a clean block or virgin cork, and requires neither more nor other dressing, being an air plant pure and simple. Manure will, however, greatly stimulate its growth; and I brought one of these plants to great perfection by a bi-weekly watering of diluted stable refuse. A little water given when the blossom opens will preserve the flower for nearly three weeks, although the scent fades out at the end of the first ten days. Those specimens, of this plant that I have seen in dealers' hands in England get neither heat, light, nor water enough, and in consequence their real beauties are seldom fairly developed, hence one of the prettiest *Dendrobiums* is lost to the public. The heat required is between 60° and 80°, when the plant is in activity, but during the season of rest, if the temperature is as low as 30°, the plant will not suffer. Perfect drainage must be insisted, as I must reiterate in the case of all orchids.

OSWIN WEYNTON.

In Assam.

FORESTRY.

THE Eurasian Association is about to start a company to grow the Casuarina. Companies to grow this tree have uniformly failed hitherto, but there are conditions which negative failure if the cultivation is undertaken by the Association. As firewood is largely used by the railways, there ought to be no doubt as to the demand. The tree does not appear to be fit for timber, and is unsuited to localities away from the sea coast, and especially those of considerable elevation. A few Casuarina trees may be seen growing about Ootacamund, but they are stunted.

AT a meeting of the Committee of the Agri-Horticultural Society of Madras, it was stated :—The Rain-tree (*Pithecolobium saman*) in the gardens, the measurements of which were given in the Proceedings of 7th August 1878, and then believed to be under six years from the seed, continues, in spite of its having been necessary to amputate some of its largest limbs, to grow enormously. Measured on 30th July last it gave in girth 9 feet 4 inches at the ground, 6 feet 3 inches at three feet high, and 5 feet 9 inches at five feet high; in spread about 85 feet from north to south; and a total height of about 46 feet. A reference to the former measurements shows that the girth at 3 feet from the ground has increased in the last three years 2 feet 2 inches. The age of the tree is, if anything, over-estimated; but search is being made for traces of the receipt of the seed, which it is believed came from Ceylon about 1872. A casuarina tree standing alongside, which was the specimen of its order when that part of the ground was laid out at the Botanical Garden, and is therefore known to be about ten years old, now measures at 5 feet from the ground only 2 feet 8½ inches, though it is about 82 feet high.

SANDAL PLANTING IN MYSORE.

LOOKING at planting in its two aspects,—of the production of strong healthy nursery plants, and of getting these planted out so that there shall be no interruption of growth,—sandal-planting is not an easy operation. The seed, a ball of soft, sticky, albumen, the size of a pea, in a fleshy fermentible pericarp, is very liable to go bad; but in ordinary soil it germinates with difficulty, so much so that it was supposed at first that the seed required, as in Nature, to pass through the intestines of birds or animals; but here it was overlooked that a bird's gizzard would be certainly destructive to the seed, and the digestion of animals most probably so, while it is a matter of observation that sandal comes up naturally in many places where there are no animals to help it. It is a fact that soaking the seed for one or two days in a mixture of cow-dung and water has been found to hasten germination; but this is observable in other seeds. The difficulty of getting sandal to germinate in the early days of forestry may be put down to bad seed and ignorance of the way to sow it.

As soon as the young sandal has come up its troubles begin; at first, during the rains, with a species of rot in which the root may be observed attacked by a fungoid-looking growth. The leaves turn yellow and drop off from below upwards, and the sandal seedling appears as a little stick with only the terminal bud left. If the attack is mild the plant makes fresh root growth, and terminal bud new leaves; but if not attended to, plants perish very rapidly in this way. I have seen a nursery of 20,000 seedlings destroyed in ten days during heavy rain. The remedy is drainage. The foresters, as soon as the disease appears, "lift" the tile-pots, taking them out of the beds and standing them on one side, high and dry, with the air playing round the pots. When the heavy rain is past, the tile-pots go back into the beds.

During the monsoon, to some extent, but more usually afterwards, many plants are lost from grubs eating the fleshy cellular portion of the tap-root. Sandal has a tap-root like a miniature radish, and it is attacked in the same manner as that and other fleshy roots.

These dangers past, it was observed in the early nurseries that something was wrong during the dry season. Here and there was a plant growing *à merveille*. One thought with horror of its tap-root for the next planting season. Elsewhere, in odd corners, a few plants pushed on steadily: the generality looked pinched and miserable, in different soils, variously manured, and properly watered. When the planting season arrived there was a small proportion of good plants left; and yet, was it not worth planting sandal even on these terms?

The remedy for bad germinations and subsequent poor growth in the nurseries has been found in humus, or the nearest thing to it, in the way of a vegetable manure, which the climate produces. The seed is sown on the tile-pot beds just covered with a mixture of sand and leaf mould. From then, till the plants are transplanted, a year afterwards, the beds are kept constantly *covered* with old leaves, dead grass, or any litter at hand. The leaves and litter, if properly watered, decay rapidly and require to be replenished at intervals of a few weeks. Last year this plan was tried in a few nurseries, and gave good results where persistently carried out. But it raised opposition;—to the careless it gave trouble, to the neat it looked very like a messy craze. During the present season it has been followed in 17 nurseries, in different hands and in different parts of the country. It is easy to account for its beneficial effect; as a matter of observation it leaves nothing to be desired in the appearance of the nurseries. The portion of each nursery under sandal is shaded with boughs so as to afford a broken half-shade similar to that in which sandal comes up naturally in thickets and hedges. Each tile-pot now contains a bunch of fine plants with the rich dark foliage of healthy sandal. There are this hot weather (1881) above a lakh of tile-pots stocked with sandal, and in many nurseries it would be difficult to find an empty pot.

Let us pass now to the planting out and management of the tap-root. In young plants the tap-root is usually longer than the height of the plant above ground. It is very sensitive to injury, and this was the cause of the failure of the early attempts to plant sandal. If cut so as to only remove two or three inches, *leaving ten inches above perfectly undisturbed in its pot*, the plant will usually die. The plan now adopted to keep the tap-root of manageable size is to have a layer of bits of broken tile strewn so as to lie flat at the bottom of the tile-pots, much as one pots plants in a flower-pot, and doing so may be presumed to afford the same advantages in the way of drainage. By this means the tap-root is stopped growing down more than ten inches, the depth of the tile-pots; it divides and accommodates itself within the tile-pot; lateral roots develope, and we obtain a form of root suitable for planting.

Transplanting begins as soon as the ground is thoroughly moistened by the first rains: it takes usually about ten inches of rainfall to do this. The tile-pots are lifted, walked away to the newly filled pits. One tile is gently removed and the cylinder of earth and root resting on the other tile slipped into the ground. The earth is filled in, and the remaining tile, gently pushed back from the roots it has protected and confined during the last year, is pulled out, and goes back with the return coolies to the nursery to be re-set, and begin its work again. Watering should be stopped in the nursery a day or two before the tile-pots are taken out, so that the earth cylinders may be as hard as possible, and the transplanting rules provide for a little watering, for a day or two after the plants are put out. It is worth noting that the best planting—the minimum of root disturbance—is during the driest weather [for the season]—a curious adaptation to the weak point of the climate.

Some one may ask why not use flower-pots instead of tile-pots? In the first place flower-pots are more expensive—all potters cannot make them, and, secondly, many of the advantages of tile-pot nurseries would be lost, *i.e.*, the shape of the tile-pot cylinders giving roots with the maximum of depth and the minimum of width—the compactness of the nurseries and consequent saving of water for each bed is a honeycomb of 100 tile-pots in a space of 50 inches + 50 inches—the ease with which the tiles can be removed from the cylinders of earth and used again in the nursery next year. The system of planting from tile-pots has been already described in the pages of this journal. In Mysore, during the past season, two and-a-half lakhs of plants were put out from tile-pots

at a saving of fifteen rupees per 1,000 plants. Of this, 5,000 odd was sandal, and the precentage of hot weather failures among the sandal was 85 per cent. It must be remembered that this was the first year of sandal-planting on a large scale, and this figure will probably be much reduced in the future. As usual, nothing was spent on watering or weeding after the plants were put out. Repeated failure is not a very serious matter on those terms; Rs. 5-8 per 1,000 plants represents the cost.

Each tile-pot contains usually more than one sandal plant, sometimes as many as half-a-dozen, depending on how the seed comes up.

There is thus a survival of the fittest for rot, grubs, and the first hot weather to work on; and then, when space is required for growth with the first monsoon after planting out, all but the best plants in each pit are cut out.

A word in conclusion about sandal plantations elsewhere. We have heard about those of Madras, and would be glad to earn more; their forest reports always late, have latterly not been sent to Mysore. It is believed that the plantation on the Neilgherries cost considerably more than Rs. 30 per acre of 500 plants, and that near the Cauvery falls is really *in situ* sowing with a suggestion of English ploughs and elephants—costly enough, and impossible for work among hills or in existing forests. Rs. 30 per acre of 500 plants is now the maximum cost of planting in Mysore, but it is hoped that sandal may do with pits 2 feet instead of 3 feet cube, and then the cost of planting will fall to Rs. 16 per acre of 500 plants.

Sandal-planting has been begun, I believe, in the Nizam's Dominions and in the Central Provinces, to both of which places seed has been sent from Mysore. There are some sandal plants now growing in the Botanical Gardens, Brisbane, from Mysore seed. Possibly the existence of frost may mark the northern limit at which sandal can be profitably grown in India. A specimen of sandal from the Nizam's Dominions compared with Mysore wood, showed a denser structure, and was nearly scentless but no particulars of the elevation at which it was grown were received. Probably good sandal could be grown anywhere in Southern India between 1,500 feet and 5,000 feet elevation, and a moderate rainfall. The higher limit would be approximately the climate of Brisbane; below the lower in Mysore, the tree looks straggling and forced, but it does not lose its scent. There is now in the Bangalore Museum a specimen fully scented, which was found growing on the banks of the Cauvery at only 1,200 feet elevation. There is a large trade in sandal between Polynesia and China, which began about 40* years ago. The people of Western Australia find it pays them better to export sandal at £7 a ton than to till the ground, and the sandal trade has been credited with atrocities in the Southern Ocean and with the present backward state of Western Australia. This wood however, is inferior stuff. Indian sandal stands as far above all other kinds in the China market as does Indian opium. It is stated that the profits of the middlemen are enormous, and that £200 a ton is a common price for first class Indian wood in China. Be this as it may, is there any other wood in the world which will fetch a *steady nett* price at the place of production of £45 a ton?—*Indian Forester.*

* Forty years ago the sandal wood trade reached a development which is accounted for by the high value attached to this wood by the Chinese. Speculators fitted out ships and cut down the forests of the Melanesian Islands. The natives naturally resisted this devastation. They were answered by the rifle. In 1842 the crews of two English vessels landed at Sandwich Islands, one of the most luxuriant in the Archipelago of the New Hebrides. The islanders, when resisting the destruction of their woods, were set upon by the whites, who killed twenty-six, and driving a great number into a cave, suffocated them with smoke till not one remained.

THE CULTIVATION OF CASUARINAS.

AT the meeting on the 3rd ultimo, of the Madras Agri-Horticultural Society, there was read an article on "The Profit of Casuarina Cultivation, published in the *Madras Mail* of the 20th July last, as an extract from *The Eurasian and Anglo-Indian Advocate*, in which it is reckoned that 18,000 trees may be grown on six acres of land to produce 8 annas each in four years, at a gross expenditure of Rs. 1,400 resulting in a net profit of Rs. 7,600, or a return in four years of 550 per cent. The Honorary Secretary, who has had considerable personal experience in this matter, stated that such estimates are liable to cause much mischief by inducing people to speculate without the means "The most successful casuarina plantors in the neighbourhood of Madras, where the land is specially adapted to the industry, plant only 800 trees to the acre, and consider themselves very fortunate if, after being twelve to to fifteen years without return for their money, they can cut an average of anything over forty tons of firewood to the acre; or if, in other words, they get their wood to market so as to give a net return, at Rs. 6 per ton, of Rs. 240 per acre. Multiplying this sum by 6, we have a return of Rs. 1,440 for six acres, against the writer's estimated expenditure of Rs 1,400. Thus, the business is only really profitable when worked on a large scale; when the trees are allowed to grow for much more than four years; when there are very good acres to make up for those that fail; and when water is close enough at hand to allow of the expenses being reduced to the lowest possible amount." We have been informed that no area under 100 acres will pay Europeans, and that these 100 acres must be good land. Natives who plant small plots make profit because they use only the unpaid labour of their own families. Last year as an experiment, a correspondent of ours cut an acre of seven-year old trees—an average one. Its produce was just under 7 tons, and the net value of the wood was about Rs. 6 a ton, so the acre yielded but Rs. 36 after seven years' waiting for returns.—*Madras Mail.*

ON THE INFLUENCE OF FORESTS ON CLIMATE AND RAINFALL.

[BY FREDERICK S. PEPPERCORNE, C.E., NEW ZEALAND.]

THE rainfall of a treeless region, even when it reaches an average limit, is always fitful and uncertain, while the rivers rise rapidly and flood the surrounding country, as has been the case lately in Hungary, the South of France, and Spain. In the former country the destruction of its forests has been a crying evil, and its results are now being felt, while every traveller has loudly proclaimed against the ruthless waste of the Hungarian forests. Mr. Bonar says that—"The Wallacks find it too much trouble to fell the trees they destory systematically; one year the bark is stripped off, the wood perishes, and the year after it is fired. In 1862, near Toplitza, 13,000 *jock* of forests were burned by the peasantry. If this goes on, a time will come when dearth of wood will make itself surely felt." And Mr. Crosse, when travelling in Hungary in 1876, says: "It is impossible to travel 20 miles in the Carpathians without encountering the terrible ravages committed by the lawless Wallacks on the beautiful woods that adorn the sides of the mountains. The great proportion of the forest land belongs to the State, hence the supervision is less keen, and the depredations more readily winked at."

If this be so, the "State" has much to answer for the future generations, and even to the present one, by its reckless disregard, since by a little foresight and skill, much might be done; and if the grand old forests of the mountains were allowed once more to re-assert themselves, we should hear less of calamitous inundations, such as that which destroyed Szegedin in 1879. Unless recourse is promptly had to some practical method for preventing the total disforesting of European countries, we must prepare to witness the depopulation of whole districts, such as has actually taken place in some parts of France and Spain, owing to the immense destruction of timber trees and forests.

All great irregularities, or partial dificiencies, or rainfall exercise, as is well known, the most detrimental influence on the progress and prosperity of the country where they occur. The conservation of the forests is therefore (or should be), one of the first duties of an enlightened Government, and the whole subject is one of paramount interest to all classes of the community, since not only the pastoral and agricultural interests, but also the great manufacturing industries of a country, are immediately connected with a due supply of water. The agricultural prosperity of India, Ceylon, Persia, China, and many other countries, suffers greatly from this cause at present, and unless aided by artificial irrigation, the consequences would be unspeakably disastrous; since in proportion to the increased area of bare soil, will be the increase of the heat and the prolongation of the drought of summer; while the annual rainfall must be more or less dependent upon the condensation and precipitation of atmospheric vapour occasioned by the masses of forests covering the uplands and mountains. These forests being destroyed, the solar heat that falls on the bare surface of an uncovered mountain, or on a great treeless plain is thrown off by radiation and reflexion, and thus raises the temperature of the superincumbent air; and the higher the temperature, the greater is the capacity of the air to sustain large quantities of vapour in a state of suspension; hence the less is the probability of rainfall.

That this is not a one-sided view to take of the subject, is proved abundantly by the results which have followed the destruction of forests in other countries Ancient realms formerly supporting dense populations, and proverbial for their fertility and prosperity, are now sterile wastes; and their mountain forests being cut down, the springs have dried up, the rivers have disappeared, while famine and destitution desolate the country, and the same effects are now being produced from the same causes in other countries which are being disforested with a recklessness which nothing but the most culpable ignorance of the invariable laws of Nature can explain but cannot excuse.

In Upper Egypt the rains, which about a hundred years ago were abundant, have ceased since the Arabs cut down the trees along the valley of the Nile, towards Lybia and Arabia, while a contrary effect has been produced in Lower Egypt from the recent extensive system of tree planting initiated by the late Khedive. In Alexandria and Cairo, where rain was formerly unknown, it has lately become more frequent, and the same effects have followed in Algeria, where the *reboisement* of the country has been carried out largely during the last 25 years, with the best result.

Professor Macarel, a French writer, observes on this point that—"Necessary as are the forests of a country to the individual, they are not less so to the State. All the wants of life are closely related to their conservation, and the existence is of itself of incalculable benefit to the countries that possess them, as well in the feeding of the springs and rivers as in their prevention against the washing away of the soil upon the mountains, and in the beneficial and healthy influence which they exert upon the atmosphere. Large forests deaden and break the force of high winds, that beat out the seeds and injure the growth of plants—they form reservoirs of moisture, they shelter the soil of the fields, and upon hill sides, where the rainwater checked in its descent by the thousand obstacles they present by the roots and trunks has time to filter into the soil, and only finds its way by slow degrees to the rivers. They regulate, in a certain degree the flow of the waters, and the hygrometrical condition of the atmosphere, and their destruction accordingly increases the duration of droughts, and gives rise to the evils of inundations."

The foregoing examples have been selected from a mass of facts, illustrative of the dependence, to a large extent, of the rainfall of a country, upon the preservation or renewal of its forests, whether it be on mountain ranges or on elevated table lands or less elevated tracts of country. And although the meteorological action of forests is as yet imperfectly understood yet the data hitherto collected are quite sufficient to point to the conclusion that trees, being the natural conductors of the electricity, as has been proved by the experiments of M. Graudeau, Professor of the "Ecole Forestriere" in France serves as intermediaries for the exchange of electricities with which the earth and the atmosphere are respectively charged.

An Italian writer on this subject states that—"Electrical action being diminished, and the rapid congelation of vapours by the abstraction of heat being impeded by the influence of the forests, it is rare that hailstorms or water-spouts are produced within the precincts of a large forest when it is assailed by a tempest"

It has also been asserted that the earthquakes which are common in some parts of Spain and Portugal would be less frequent and less violent if the elevated regions of those countries were clothed with forests so as to secure a regular and harmless conduction of the electric fluid or agent from the aerial to the terrestrial reservoir and *vice versa*. This is extremely probable, and one thing at all events is certain, which is that hailstorms, which are believed to be produced by certain specific electric action, become more frequent and destructive in districts which possess no forests. On this point Signor Calvi, states in his *Hints on the Importance and Cultivation of Forests,* that—"When the chains of the Alps and the Apennines had not yet been stripped of their magnificent crown of woods, the May hail which now desolates the fertile plains of Lombardy was much less frequent. But since the prostration of the forests, these tempests are laying waste even the mountain soils, whose older inhabitants scarcely knew the plague."

In our vast Indian empire, the Government, until lately, permitted a wholesale destruction of the State forests, but now the forest question is being regarded as one of the first importance, and is being dealt with not by the several presidencies, but by the general Government, on behalf of the country at large, by the appointment of forest conservators, whose duties are to see that the trees cut down are replaced by others, so that the annual growth may be made to balance, as near as may be, the annual con-

sumption. The consequences of this reckless destruction of the Indian forests have already made themselves severely felt by the greater frequency and length of seasons of drought and famine, and with such data as are accessible in late reports, it cannot be doubted that these calamities are in a great degree due to the reckless denudation in years past of the forests.

Enough has now been said to show the calamitous consequences of denuding a country of its woods and forests and to show that writers have acknowledged repute who have made this subject their special study, are unanimous in connecting the occurrence of droughts with all their attendant evils, together with the outbreak of certain malarious epidemics with the reckless destruction and waste of forests.

During the last half century great attention has been paid to this subject both in France and Germany, in both of which countries the art of "Forestry has been largely developed, an art which comprises an extensive range of knowledge in various sciences—such as botany, chemistry, geology, and vegetable physiology. At present the area of the French State forests is put down at fully 3,000,000 of acres, to which may be added upwards of 5,000,000 belonging to "communes," corporations, hospitals, and other public establishments, the whole of which are under the supervision of the French Administration of Forests. In the Vosges, the destruction had gone so far that the humidity had diminished, while the soil had become more arid and inundations more frequent. In the department of the Gard it did not rain in 1837 for more than nine months, and the supply of water from wells was most seriously diminished.

At Bergiors it was reported that the vast forest which once sheltered that place having been destroyed, the loss of the slave cropwas the immediate result; violent storms and torrents of rain certainly fell from time to time, but these, from their violence, did more harm than good, as the water washed away the soil without penetrating into it. At the present regulations that have been put into force by a wise Government for the conservation and management of the forests are of the most stringent nature.

In Prussia Proper, out of 35 millions of "hectares"* eight millions are classed as forests, out of which nearly four millions are private forests, and in both cases the regulations for their management and conservation are sufficiently comprehensive.

In Switzerland the question of forest conservation has become of such national importance that it has been proposed to modify the constitution in order to enable the Federal Government to undertake duties which have hitherto been performed by the several cantons.

In Austria the management of forests has recently been transferred from the Finance Minister to a distinct department presided over by the Minister of Agriculture.

In Canada there has been a certain amount of legislation on this subject, but in France, Sweden, and Norway the most rigorous measures have been devised for the protection of the forests even of private owners. A tabular statement of the proportion of forests remaining in different countries gives the following results:—

	Per cent.		Per cent.
Great Britain ...	5·55	Spain ...	5·60
France ...	16·00	Portugal ...	4·40
Belgium ...	18·50	Denmark ...	5·50
Sweden ...	60·00	Holland ...	7·10
Norway ...	65·00	Italy ...	20·50
Germany ...	26·10		

In the Australian colonies of Victoria, South Australia, and New South Wales, the evil produced by a gradual diminution of the forests have begun to make themselves felt and with the destructive bush fires, have combined to render the climate, which is naturally a dry one, still more so from year to year. The indigenous timber in these colonies is disappearing with such rapidity that unless immediate steps are taken to conserve large tracts of existing forests, the consequences must inevitably be of the most serious description.

Of course there are large areas in all the colonies where there are no forests to preserve, and here it would be necessary to create forests by tree-planting on a large scale. This is no new suggestion, as some years back a proposal was made in Victoria, which met with the general approval of scientific men, that the fiery blasts of the hot winds might be tempered by the state taking in hand from year to year, the planting of belts of trees at intervals along the northern parts of the colony. This proposal was not acted upon, neither was a scheme of forest conservation, which seems to have been based upon sound and common sense principles, and therefore was ignored. It was proposed to let out timber reserves in areas of sufficient extent to enable the work of destruction and replantation to proceed *pari passu*. In each area, for example, not more than one-twentieth was to be cleared in any one year, and in the year following this was to be replanted with young trees, under sufficiently stringent condition to secure performance, and thus the forest growth would be secured, as from 20 to 30 years, it is said, is the average period required for the *eucalyptus* tree to arrive at maturity.

This would secure an object of immense importance in a climatic point of view, while the annual supply of timber would suffer no diminution, and the economical value of the forests would be maintained. If a beginning were once made under the auspices of the State, which is the proper conservator of woods and forests, it is highly probable that destructive droughts in future would be to a considerable extent mitigated, and what we see to be both sound as a matter of scientific inquiry, and which had been verified by observation and experiment, on a small scale, is capable of being done on a large scale, so as to produce very beneficial results.

Unless recourse is had to some such practical method as is here pointed out for preventing the total disforestation of the mountain ranges in Australia, we must be prepared to witness, at no very distant period severer droughts occuring more frequently, and of longer duration than before, to the utter ruin of pastoral and agriculture pursuit in all the colonies.

In South Australia the subject has, however, received some attention of late, and proposals have been made by Mr. Goyder, the Surveyor-General of that colony, to initiate and carry out a systematic course of tree planting. Mr. Goyder proposes to reserve a block of 200,000 acres of land, and to spend on it, in tree planting and management, £14,000 during the first year, and £10,500 during each of the following 11 years, thus making the total expenditure £130,000, when the whole of the 200,000 acres would be planted and fenced in. During the first five years, there would not be any revenue, but during the sixth, seventh, eight, and ninth years, the revenue from periodical thinnings he estimated at £35,000 per annum, until the end of the 21st year, when the colony would be in possession of 200,000 acres (or 310 square miles) of forest.

It is possible that this estimate of revenue may be a little overdrawn but the scheme is an excellent one, when it is considered that the forests of *eucalyptus* are vanishing in all directions, and it is to be borne in mind that in no case is the natural forest, or as it is colonially called 'the bush,' so valuable, commercially speaking, as a planted forest, carefully attended to. Probably, however, it would be found to be more advisable to make the areas smaller, and, in lieu of one block of 200,000 acres, to make four blocks of 50,000 acres planted in different localities, which would exert a more beneficial influence on the climate and rainfall of the interior.

If, on the other hand, the continuous denudation which has been continually going on for nearly 60 years in Australia, is still to be continued, then will the changes in the climate produced thereby entail on future generations evils of incalculable extent, which must prove fatal not only to the successful prosecution of all the pursuits of husbandry, but also to the future habitability of the country, for nothing less than this is really involved in the momentous question under consideration.

The whole topic of forest conservation and tree planting, and consequently of regular and well balanced rainfall, is one of such paramount importance in the colonies, that it needs only to be pointed out clearly in order to prevent the disastrous consequences which must result from further apathy or negligence. Through the continued alternation of very wet and very dry seasons, the productiveness of the soil will be gradually reduced, and large areas now covered with a luxuriant herbage and vegetation, will, in time, become as arid as the Central Steppes of Russia and Siberia, and like them become cheerless and barren deserts.

We are, in Australia, and New Zealand, much in the same position as the inhabitants of India, in this respect, that we are only beginning to feel the calamitous results of the wholesale destruction of our forests. And even in New Zealand the cutting down of the timber is beginning to tell on farming pursuits, though, fortunately at present, without doing any material harm.

Dr. Hochstetter in his valuable work on the geology and natural history of New Zealand, pointed out the fact that extensive districts which had formerly been covered with forests of kauri pine, were, when he wrote so no years ago, totally destitute of this most valuable of forest trees. He also said that its extermination was progressing from year to year at such an alarming rate that its final extinction was as certain as that of the natives themselves, only in a much shorter period of time.

Dr. Hector also, in a very interesting paper showing the percentage of the forest lands in New Zealand to the whole area of the colony made the following estimate of the destruction of forests between the years 1830 and 1868:—

In the Province of—	Per cent.
Auckland	58
Taranaki	10
Wellington	20
Hawke's Bay	60
Nelson	16
Canterbury	10
Otago	12
Marlbourgh	12

This shows that the average annual destruction of the New Zealand forest during the 38 years terminating in 1868, was at the rate of about 23 per cent., while during the five years from 1868 to 1873, it was estimated that the following amount was destroyed, out of that which remained in the former year:—

In the Province of—	Per cent.
Auckland	27
Taranaki	11
Wellington	25
Hawke's Bay	30
Nelson	20
Canterbury	53
Otago	10
Marlborough	28

In other words, taking the average of the whole colony, 20 per cent. of what forests remained in 1868, had been destroyed in five years. It will be observed that at this rate of progress of destructiveness, very little, if any, of our New Zealand forests will be in existence at the end of the present century, and such being the facts of the case, with periodic droughts in all the Australian colonies of greater severity looming in the future, and which will be mainly attributable to the annually increasing denudation of their forests; with springs and streams drying up, with a grass famine staring the colonists in the face, and the country becoming unfit for pastoral or agricultural pursuits, it is surely incumbent on the Legislature to take some steps for the preservation of the State forests.

In such a case it is unquestionably the duty of the State to set the example. The most stringent measures will have to be adopted; every municipality, should have its "forest reserve" adjacent to it, if possible, and every encouragement should be given to landowners towards the planting of large numbers of trees on their estates.

Sir Julius Vogel said this in 1874, and a valuable state paper was published in that year, showing clearly the necessity of preserving the New Zealand forest, as well as the injurious effects following their destruction. He also pointed out that what is required, and in fact demanded, in the interests of the colony is a system of forest falling by selection and of planting, under State supervision, in order to repair the annual loss of timber.

Unless this is done, and should no steps be taken in this direction, the consequences must inevitably be most disastrous, to the future prosperity of all the colonies, some of which are beginning to suffer from the scourge of alternating disastrous floods and still more disastrous droughts due chiefly to the destruction of the forests.—*Australasian*.

* A *hectare* is equal to $2\frac{1}{2}$ acres.

TEA.

The quantity of tea exported from China to the United Kingdom from the 1st June to the 18th of August this year was 80,076,095lbs., as compared with 82,774,374lbs. exported in the corresponding period of last year. The quantity exported to the United States of America from China and Japan in the same time was 27,043,960 lbs. as against 25,702,483lbs.

THE number of coolies imported into Cachar for the tea gardens, was 1,527 as compared with 3,077 for the preceding year, a decrease 50 per cent. This decrease is not due to any falling away of the industry, but to the fact that the improving communications which now exist between the recruiting districts and the tea gardens, has led to a large number of labourers finding their way to the gardens without the intervention of the coolie contractor and his multitudinous following. This will speedily make the Emigration Act a dead letter, when the prices of labour may be expected to fall to more reasonable rates. The total number of "Act" coolies in the province at the close of 1879 amounted to 62,547, and at end of 1880 this number had fallen to 60,714, a decrease of 2·93 per cent. The population of the province exhibits a great change since the census of 1872 was taken. Then the numbers were 205,027, whereas there are now 334,326 people in the province. This increase is 63 per cent., or at the rate of 7 per cent. per annum. While the general population has increased so enormously, owing to the extensive immigration which has been going on for the past 25 years, the hillmen are decreasing in number, the figures for 1872 and 1881 being 30,000 and 22,379, a fall of 25·4 per cent. This seems the fate of aboriginal tribes all over the world; they become improved off the face of the earth before the advance of civilisation.

A tea-planter has written from Assam to the *Rangoon Gazette* pointing out what a splendid field for tea cultivation this province presents to speculators. Doubtless there are many parts of our hills from 2,000 to 4,000 feet high where tea and coffee would flourish luxuriantly. But we certainly require more liberal land laws before we can hope to attract capital and labour to Burmah. Every thing now is in the hands of the district officer, and he on the most flimsy pretexts has it in his power to resume land from the grantees. Then, again, Government have decided only to lease land in Burmah instead of giving, as in Lord Canning's time, the fee-simple where there are literally millions of acres of land available. Why should not land be given out and out to *bonâ fide* capitalists anxious to introduce new industries? Land Companies might then easily be brought out in England for taking up land in Burmah, just as they have been for Australia, New Zealand, and other English colonies. But capitalists will not put their money out on land which under the present system may be resumed at the whim of some interfering Deputy Commissioner, just as it is on the eve of becoming remunerative.

INDIAN AND CHINA TEAS.

THE following tables, compiled at the Industrial and Technological Museum by Messrs. Cosmo Newbery and F. Dunn give the average results of a series of analyses of teas carefully drawn from the bulk.—

Season.	Percentage of mineral ash.	Percentage of extracts.	Percentage of soluble salts.	
1880-81 Auction Sale Indian Tea, 15 samples =770 hf.-chests, avgs.	5·81	39·12	3·16	
1880-81 Auction Sale Indian Tea, 46 samples =3,131 half-chest., avgs. ...	5·46	42·40	4·06	
1881-82 Auction Sale Indian Tea, 36 samples =1,812 hf.-chts., avgs. ...	5·54	43·91	3·27	
1880-81 Auction Sale Foo Chow Congous, 15 samples=1,904 hf.-chts., avgs. ...	5·40	29·26	2·88	
1881-82 Auction Sale Foo Chow Congus, 50 samples=2,880 hf.-chts. avgs. ...	5·40	31·30	3·60	
1881-82 Auction Sale Foo-Chow Congous, 20 samples common=6,220 hf.-chts., avgs.	5·32	33·60	3·26	First crop teas.
1881-82 Auction Sale Foo-Chow Congous, 20 samples medium=1,152 hf.-chts., avgs.	5·40	35·20	3·48	First crop teas.
1881-82 Auction Sale Foo-Chow Congous, 10 samples good = 1,957 hf.-cht., avgs.	5·44	35·04	3·54	First crop teas.
1881-82 Auction Sale Foo-Chow Congous, 10 samples fine=957 hf.-chts, avgs. ...	5·50	34·32	3·52	First crop teas.
Genuine Tea of lowest class contains	4 to 6	32	3	

N. B.—The result in favor of Indian teas is too marked to need further comment. Many of the China teas will not pass the standard of a genuine tea.

COFFEE.

THE most astounding results are reported of the cultivation of coffee from the Bourbon seed. A Brazilian planter states that he has obtained 30 cwts. of coffee to the acre from this variety, only 4½ years in the ground. Locally 10 cwts. an acre is a highly profitable yield, but a ton and-a-half would beat gold into a cocked hat.

THE Americans are anxious to introduce Liberian coffee to the United States consumers of the beverage. Mr. E. S. Morris of Philadelphia deals in coffee of this description, and undertakes to dispose of consignments to the best advantage.

CINCHONA.

A CORRESPONDENT writes to a contemporary—have you been told of the new enemy of the cinchona tree that we have found out? The coolies taking off the bark about a foot up from the ground, and selling it in the villages. The wily native finds a decoction of it good for fever. I came across (this morning) one of my finest trees that had been robbed. You should give cinchona planters the hint to keep watch. It is not merely the loss of the bark, but the tree is liable to be injured if not destroyed, should they ring the trees.

THERE are few Government concerns that can compare results financially with the cinchona plantation and factory near Darjeeling. The latest report of the Government Quinologist, which deals with the year 1880-81, discovers no falling off in the prosperity of either. The profits of the year's working amount to Rs. 80,290 over and above the saving which the Government effect by the substitution of the febrifuge made at Darjeeling for quinine, which is itself estimated at four and-a-half lakhs per annum. The reason why there is comparatively so small an actual profit in rupees, and one so immense on the sale of the febrifuge is because the factory is debited with the bark used at actual cost, and not the price at which it would sell in open market. Our Allahabad contemporary is much pleased at the success of this Government undertaking. We are equally pleased, but in this very success we see a strong reason why Government should now retire from the industry. It is the duty and interest of the Government to undertake the initial and experimental stage in all such industries, a work which is generally beyond the power of private enterprise. This over, and the success of the new industry assured, the duty of Government is then to withdraw, and hand over its work to some company. This was done with tea, and will doubtless be done with cinchona as well, and we think the time has arrived when this ought to be done. When the profits on the manufacture of febrifuge and growth of bark amount in one year to more than the entire capital invested, it may safely be affirmed that the industry is a success, and if it be beneath the dignity of Government to make a profit by selling coals, it ought to be equally inexpedient to sell febrifuge. It is no doubt true that the sale of this medicine is presumably doing much good, but this would be equally true if it were made by private enterprise. We trust, therefore, that the Government cinchona plantations in Darjeeling and on the Neilgherries will soon be advertised for sale.

CINCHONA is not a new industry here, for as far back as the year 1865, a healthy movement was made by a private firm to plant different parts of the country with it, and it was carried out to a certain limited extent; but the next year and those following, it lapsed into disuse, and became neglected. It lacked encouragement and was never thought to have such a brilliant future in prospect, as it has now attained, and coffee was giving sure and quicker profits; so that until 1877 the few hundred *C. succirubra* trees which were left and had survived, and that without any care or attention, were simply regarded as curiosities, and samples of what the soil could produce, if it ever became necessary to encourage them. (I do not here allude to the Rev. Mr. Richter's cinchona garden, which has steadily been cultivated since 1863.)

IT is a fact worth noting that of the 1,080,209 lbs. Cinchona shipped from Ceylon to the date of the last Chamber of Commerce Return, during the current season, over 300,000lbs. were bought locally and shipped by Continental houses to Quinine manufacturers in Europe and the United States. One of these houses shipped over 200,000lbs. or one-fifth of the total quantity. There can be no doubt that this new element of competition has been to the advantage of the growers, whilst at the same time this new trade with continental ports will help to stimulate the manufacture of quinine in those countries.

CACAO.

CACAO IN BRAZIL.

BETWEEN the Rio Negro and the Xingu, the most important lowland crop is cacao. It is true, the trees will grow quite as well or better on the *terra firma*, but Brazilians prefer the *varseas* for their plantations because the ground is easily prepared and takes care of itself; besides, the orchard arrives at maturity much sooner. We hardly notice these cacao plantations from the river; the dark green of the foliage is so like the forest, and generally there are other trees near the shore. But for miles the banks are lined with them, mostly the orchards of small proprietors, who own a few hundred *pés* of cacao, though some of the estates have twenty or thirty thousand trees. In our wanderings about the lowland we often pass through these cacoas. They have a rich beauty of their own,—the dense foliage, twilight shade beneath, and the dark [illegible] leaf or five, together with the fruit

growing, not among the leaves, but directly from the trunk and main branches, attached only by a short stem. The ground is quite clear and free from underbrush, and in the summer when the fruit is gathered is for the most part dry. The harvest months are July and August when the gatherers go every day to pick the ripe fruit from each tree and bring it in baskets to the house. There the oval, ribbed outer shell is cut open and the seeds are washed from the white pulp; then they are spread over mats and placed on raised stagings to dry in the sun; care being taken to turn them at intervals. Most of the seed is exported in this form; a little is roasted, pounded, and made into cakes with melted sugar for the delicious chocolate of the country. Unfortunately on the mazons the sun is a very uncertain drying agent; frequently there are heavy showers, and the sky is clouded for days together; so it often happens that the imperfectly prepared seed gets musty and half-rotten before it reaches the market. Much of the Pará cacao therefore, does not rate very high with the manufacturers. All this might be avoided by the introduction of a simple drying-machine, such as is used at Rio for coffee. Stopping at the *fazendas*, we frequently get a refreshing drink, made from the white pulp which surrounds the cacao seeds. Enterprising planters prepare from this pulp a delicious amber jelly, which if it were placed in the market would be much more popular than guava jelly. Even the shells are valuable; they are dried and burned, and from the ash is prepared a very strong brown soap—a necessity to every Amazonian washerwomen.

We could call the attention of cacao planters in Ceylon to these last sentences, from which it will be seen that the cacao pod is of value in more than one way.—*Ceylon Observer*.

SERICULTURE.

THE silk industry is reviving in Louisiana, the reports of the hatching of 1881 being very encouraging. Interest in the culture is growing and inducements are offered to silk workers to come from France and engage in the business. The first exports of silk from Louisiana were made as far back as 1718. The culture of silk is being revived in South Carolina and Georgia.

THE following particulars regarding the Japanese silk industry are contributed by a correspondent, who has recently returned from a tour in the silk-producing districts, to a Yokohama paper:—"During a visit made during the last few days to the silk districts of Busho and Jusho, I have been enabled to verify the fact that the education of silkworms has not had any very great success in those two provinces. All went well until the fourth stage; but at that critical period great heats occurred, which caused the worms to commence spinning, without being sufficiently nourished, and the cocoons thus produced were poor and light. The Japanese are greatly disappointed with respect to this, and talk of a deficit of at least 15 per cent. In fact, along the the entire route, from Kumagai, Hunjo, Shinmachi, and Tamamura to Maibashi, one saw very poor samples of the cocoons of this district. A large proportion of them have rotted, for—in consequence of the bad weather—there has not been time to dry in the sun all the cocoons which it was intended to have reeled. This will naturally, largely diminish the product of these districts, and if one thinks of the haste of the Japanese to spin, as quickly as possible, those cocoons which are daily being spoiled before their eyes, the inevitable interference can be drawn that the *recolte*—in the above-mentioned district—besides being short in quantity, will also be very defective in the qualities of regularity of size and cleanliness."

THE following statistical remarks on the silk industry in the United States should be of interest to Japanese and foreigners engaged in the silk trade of Japan:—

With a rate of duty ranging from 60 to 120 per cent., there were imported into the United States last year $33,305,460 worth of silk goods of foreign manufacture. This is an increase of nearly $8,000,000 over 1879, and $13,000,000 more than in 1878. It is desirable that the United States should import none but the raw silk, if, indeed, it prove impossible to raise our own silkworms, and the duties have been maintained at their present excessive rates mainly with the view to protect the domestic manufacture. This is conducted chiefly in Connecticut, New York, Massachusetts, Pennsylvania, and New Jersey, and has proved very successful as regards certain classes of goods. A silk manufactory on quite a large scale was established in Baltimore about 1870, but it did not prosper, and the enterprise was abandoned. Our present silk manufacture, as will be seen below, is very small. Gov. McClellan in his last annual message, in adverting to the valuable work of the New Jersey State Bureau of Labor and Industries, said that his State consumed more than sixty per cent. of the raw silk imported into the United States, and that it was eminently desirable to have some action taken upon the recommendation of that bureau in favor of extending special encouragement to the culture of the silkworm. The Jersey silk mills give employment to 13,932 hands to whom they pay wages to the extent of $4,047,745—$300 per capita, which is considered nominally good wages, considering that a good many of the employés are women and children. The gross value of the manufactured silk products in the United States for the census year 1880 was $40,975,285, the gross value of materials and supplies for this manufacture was $22,371,400; the net value of finished goods was $34,410,463; the number of silk factories in the country was 383; the capital real and personal, invested in this industry was $18,899,500; the number of looms at work was 8,467; the maximum number of hands employed during the year was 34,440, including 9,350 males over sixteen years of age, 16,341 females over fifteen years old, and 5,605 children and youths who received $9,107,835 in wages, equal to $264 per capita.

TOBACCO.

WE take the following from an old chronicle:—"I have been told that in the last great plague at London none that kept tobacconist's shops had the plague. It is certain that smoking was looked upon as a most excellent preservative, in so much that even children were obliged to smoke. And I remember that I heard formerly that Tom Rogers, who was yeoman beadle, say that when he was that year, when the plague raged a schoolboy at Eton, all the boys of that school were obliged to smoke in the school every morning, and that he was never whipped so much in his life as he was one morning for not smoking.

THE quantity of tobacco consumed in the world must be enormous. Some curious statistics relating to tobacco smoking in France appear in the Belgian *National*. It appears that there are 5,671,000 smokers, each person smokes an average of 9lbs. a year. For every fifteen smokers, eight smoke pipes, five cigars, and two cigarettes. The total consumption of cigarettes is estimated to be 294,000,000,000 per annum, that is, 800,000,000 a day, 33,000,000 an hour, 550,000 a minute, 9,166 a second; finally, if all these cigarettes were placed end to end they would reach 514 times round the globe. This is for France alone, and we imagine there are countries where more tobacco is used than in France, Germany for instance. France makes a considerable profit from the monopoly she enjoys in connection with tobacco, and there is no valid reason why tobacco should not be heavily taxed. It is clearly a luxury, and not a very good one at the best. The question of making this article a monopoly in India has often been discussed, and has invariably been laid aside on account of the difficulties attending the administration of such a monopoly, and because of its being looked on in India as a necessity of life. We do not see much difficulty, provided the several native Governments would likewise make its cultivation subject to such rules as control opium cultivation. Its universal consumption, which is urged against the proposal, is, in our opinion, the very reason why tobacco is a suitable article for monopoly. Excepting salt, it is the only article on which a tax would be of universal application, and it would enable the Government to lighten that on salt. This latter, although very light, is open to the objection of being a tax on a positive necessary of life.

SINCE the commencement of tobacco growing by the Government, and more recently by the enterprising proprietors of the Poosa Farm, with a view to prepare the weed for European consumption, much has been done. We learn that 13,723,660lbs. of tobacco, worth only £126,322, were exported from India in 1878-79. In the following year a less quantity was exported, but the total value had slightly risen. This would seem to indicate an improvement in the quality of the exports. The fact that the value of non-Indian tobaccos has been falling during the interval, puts the prospects of the Indian trade in a still more favourable light. The few who have really studied the subject know that, in the estimation of London agents and merchants, the Indian leaf only requires the labour of skilled curers to compete successfully with the produce of America and the Manillas. The native agents here are the persons who are chiefly responsible for the abominably bad way in which the leaf is prepared. This shows clearly that the general quality of Indian tobacco is improving. The recent withdrawal of the Spanish Government from the Manila monopoly should further advance this trade, and if only the native growers would procure good seed, and bestow more attention on curing, there is no reason why Indian tobacco should not be equal to the very best in the world.

ADVERTISEMENTS.

TO PLANTERS.

A GENTLEMAN with 6 years' experience in general cultivation in Southern India, a sound knowledge of Agriculture in all its branches, and a two years' experience of the Mincing-lane Tea Market, is desirous of obtaining a post, as Acting Manager on either a Tea or Indigo estate. Will undertake the Analysing of Soils, and the supply of Chemical Manures.

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

ON THE BARK OF THE *BROUSSONETIA PAPYRIFERA* AS A MATERIAL FOR PAPER-MAKING.

I.

TO THE EDITOR.

SIR,—You have done our English paper trade good service by directing attention to Dr. Brandis's memorandum on the above paper-making material in your journal for August last.

I do not believe there exists in the whole world a more valuable fibre for paper-making than this bark, and it possesses the great advantage that it requires no mechanical treatment, the stripping and cleaning of the bark being effected by hand labor, and, as Dr. Brandis remarks, its cultivation also is of the simplest character, "*Coppice-wood on a short rotation similar to osier beds.*"

The wonderful paper made by the Japanese for ages past (its introduction dating A.D. 610) is produced from this bark, and although the paper they make is not fitted for European requirements—merely owing to the peculiarity or fashion of its manufacture—a practical investigation of the bark itself can leave no doubt as to its value: it is, indeed, far too strong and fibrous for the ordinary papers used in England, if worked by itself alone, but its great value consists in the superior quality it would impart if used as a blend for mixing with and strengthening the materials now currently employed; used, in fact, as we paper-makers employ fine flaxen hempen rag material.

I believe I am correct in stating that it will be found some of the varieties of the silk worm (tussor and others) feed on the leaves of the Broussonetia, and thus two industries might be promoted simultaneously, as after the leaves had been utilised for the worms the branches would remain for cutting and furnishing the bark for paper stock.

Some years since on a visit to Italy I endeavoured to procure the branches cut from the white mulberry, which there furnishes the food for the silk-worms, the trees being pollarded and the branches cut down every season, but I failed, owing to the irregularly distributed growth of the trees, and the consequent cost of collection for so widely diffused a material, besides fuel being scarce and dear the custom is to use these shoots for pot-boiling.

This would not, or need not, be the case in cultivating the Broussonetia on a regular system, as planted regularly like osiers are in this country (and in Japan) they would be cropped continuously as Dr. Brandis observes "on a short rotation."

Although thus drawing attention to the Broussonetia it must not be supposed I relinquish my predilection for bamboo, the first being considered an "article de luxe," the latter an "article de necessité," and preferable in so far that it already exists in exhaustible quantities in the native forest at present as it were a waste product only requiring collection, whereas the first demands cultivation, and

although probably superior in quality would require years to furnish an adequate supply, while the bamboo can be used in its entirety, can certainly be produced at less cost, and is more generally adapted for most classes of paper.

The action of the French in Tunis and Algeria will most probably seriously affect our supplies of esparto grass in the future, and as we in England, are mainly dependant for this our chief paper material from Northern Africa, the time should be most propitious for stimulating enterprise in the production and export of paper-making materials from India.

The Crimean War was the stimulus to the jute trade, as previous to 1856 the imports did not amount to 30,000 tons annually; they now exceed 400,000 tons. In like manner the Confederate War in the United States inaugurated the use of esparto, as up to 1861 when my process of treatment was introduced I was the sole user for paper-making, and last year the importation exceeded 200,000 tons. It is said that a retrospect of the past is the truest guide to the future.

India can supply the world with paper material, *as cheaply, as abundantly*, and *of better quality*, than that we now are compelled to use. I desire to impress the fact on those interested in Indian commerce, and shall be happy to communicate with parties desiring to entertain this branch of industry.

THOS. ROUTLEDGE.

Claxheugh, Sunderland, Sept. 12.

II.

SIR,—In my last communication referring to Dr. Brandis's memorandum in your August number, directing attention to the above bark as a valuable adjunct to our supplies of paper-making material, I now forward you the *St. James' Gazette* for the 21st September, drawing your notice to an article therein on "Silk-growing in Burma"* written evidently by one fully conversant with the subject.

I think you will do good service by publishing this article *in extenso* in your journal, and I need only remark that the "Burmese Mulberry Bush" the "poh-tsa-bin, the tree the silkworms eat" is the Broussonetia papyrifera, the tree referred to by Dr. Brandis.

"From small beginnings great things spring," and I trust that the notice I doubt not you will attract to this question in your journal, may, as suggested in my last letter, induce attention to the subject, and, that a stimulus may thus be given to two new industries simultaneously, *viz.*, the increased production of a silk, which, although it possibly may not be equal to Italian and French, or even Chinese, will bring good value in our Home market, while the bark from the shoots cut down every season when denuded of their leaves will form a valuable paper-making material when converted into "stock."

For some time I have given attention to this class of material, and having obtained some of the Broussonetia bark from Burma, after a long series of experiments, have matured a simple process of converting the same into a fibrous paper-stock of very high quality, this process also being applicable to several other indigenous barks which, although not of so high a quality as the Broussonetia, may still be utilised at fair profit for paper-making material.

I am satisfied that a new and wide field is thus opened to British Burma, the most flourishing province of our great Indian Empire.

THOMAS ROUTLEDGE.

Claxheugh, Sunderland, 28th September 1881.

* The article on Silk in Burmah will be found among our selections. —ED., *I. A.*

SULPHURIC ACID FOR ASSISTING GERMINATION.

TO THE EDITOR.

SIR,—In your issues for September and October there are some statements with regard to the use of sulphuric acid in promoting the more rapid germination of seeds or fruits contained in shelly capsules, such as nuts, &c. The tea seed is contained in a shelly capsule, very much resembling a nut, and if a few days could be gained in the germination it would be of some benefit to planters.

If you happen to know the proportion of sulphuric acid to be used or the solution, and will kindly inform me, I should like to try the experiment with some tea seed, and will let you know the result when the seeds germinate, if you should care to hear.

CHARLES P. BRUCE.

NOTE.—See an Editorial Note elsewhere.—ED., *I. A.*

The Indian Agriculturist.

CALCUTTA, NOVEMBER 1, 1881.

ADMINISTRATION OF THE CENTRAL PROVINCES.

THE Central Provinces administration report for 1880-81 is to hand, and appears much earlier than these reports usually do. The area under the Chief Commissioner is as follows in square miles :—

		British.	Native.	Total.
Cultivated	...	24,108	5,440	29,548
Culturable	...	25,733	12,949	38,682
Unculturable	...	34,367	10,445	44,812
Total	...	84,208	28,834	113,042

Thus out of the whole culturable area only 43·3 per cent. has been brought under the plough. This was to be expected from the paucity of population, which, over all the province, is in the proportion of only 81 to the square mile.

Details regarding four crops are given very fully, and give us a fair idea of the state of agriculture in the several districts. We summarise these details thus, the figures being per imperial acre :—

		Average Rent.	Produce in lb. Min.	Max.	Average.
Rice	...	Rs. 0 9 0½	245	680	461
Wheat	...	„ 1 8 7	364	768	594
Cotton	...	„ 0 15 10	17	128	54
Oil Seeds	...	„ 0 13 1	100	440	231

These figures are striking. They are all low, very low, and the discrepancies, especially in the produce of cotton, are great. It passes comprehension why the cultivators in Raipore continue to grow cotton year after year, with an out-turn of 18lbs. per acre. During the year the price of cotton in Raipore averaged Rs. 20 per maund, so that the gross value of the out-turn was only Rs. 4-6-3 plus the value of 36lbs. of cotton seed. On the experimental farm at Nagpore cotton was tried with the result of producing 90lbs. after the land was ploughed with the American plough, and manured with ten tons of *poudrette* per acre. Three acres were cultivated, and irrigated twice, yielding 103lbs. cotton and 301lbs. seed per acre. Prices of food-grains were very much lower than during the previous year, and the general condition of the people was better in consequence.

There are now 19,666 square miles of forest as under :—

First class reserves	...	2,535
Second class reserves	...	16,850
Unreserved	...	281
Total	...	19,666 sq. miles.

This is regarded as satisfactory, but it should be remembered that the more these forests are reserved, the higher becomes the price of firewood, and this again re-acts on the manure supply, and leads to a larger quantity of *oopla* being used.

We are told that the Charwa Agricultural Company has collapsed. This company started with a great flourish of trumpets, and took up land in the Hoshungabad district, intending to carry on agricultural operations on a grand scale. The report is silent as to the cause of the failure, and we should like to have known something about its working and its collapse. There is room for many such companies, and much good might be done by wealthy companies taking up extensive grants, and sub-letting the same to settlers, helping them by financing on reasonable terms. The company could do this at rates and on terms much under those of the ordinary money-lender or village *bunia*, and still secure a good return for the funds invested.

The revenue assessment is classified in a very close and detailed manner in the last administration report. It

is as follows: On cultivated land, it ranges from 2as. 4 pies per acre in Sumbulpore, to 11as. 4 pies in Nagpore, the average being 6as. 10 pies. On culturable land, not under cultivation, it runs from 1 anna in Mundla, to 9as. 2 pies in Nursingpore, the average being 3as. 4 pies, or as near as may be one-half of the other. Over the whole area of settlement, the annual charge runs from 6 pies in Sumbulpore, to 6as. 5 pies in Nagpore, the average being 2as. 5 pies per acre. This is the custom all over India—to charge less on land not under cultivation during any given year. It is also followed by most zemindars in exacting rent. We do not think it is an equitable system. As well might the tenant of a dwelling-house be exempted from payment of rent during the season he and his family spend at the coast. It would be much more in accordance with reason, if a rate was charged irrespective of whether the tenant chooses to cultivate or not, as the land is as much out of the landlord's hands, so far as re-letting is concerned, when the tenant does not cultivate, as is the dwelling house of the family whose members vacate it for several months every year.

The Government of the Central Provinces do not seem to have done much in the way of irrigation. We find the following statistics to represent the irrigated land under the Chief Commissioner's government—

Land irrigated by Government	...	214 acres.
Do. by private individuals	...	836,297 "
Total	...	836,511 acres,

that is to say, out of every hundred acres, private individuals have provided for 99·97. Of the total under cultivation, which amounts to 13,844,031 acres, only 836,511 are irrigated. This is only 6 per cent. of the whole. Surely something more might be done by Government.

The farmers are comparatively rich in draught cattle, as we find they possess no fewer than 5,670,178 cows, bullocks, and buffaloes. They have, however, only 777,801 ploughs, and as this is one plough to every 18 acres under cultivation, there is room for improvement. The influence of the railway and of other means of communication is clearly seen in the price of food-grain in various districts. For instance, in Bilaspore the average price of rice was 12as. 3 pie per maund, while in Hoshungabad it was Rs. 4-8-0. The rent of rice land was 6as. per acre in Sumbulpore, and Rs 5 0 0 at Nimar. There is much room for improvement in the agricultural attainments of the ryots, the average produce in lbs. per acre of various crops having been as follows:—

Rice	...	410
Wheat	...	529
Goor	...	481
Tobacco	...	199

The outturn of tobacco in the Punjab being 800lbs. per acre. The soil is good, but the rainfall is variable, and often deficient, hence the urgent need for Government to step, in and do something towards improving the irrigation of the provinces.

NOTES FROM A COTTAGE GARDENER.

I.

Sowing Seeds.

(Communicated.)

THE condition in which the ground ought to be to receive garden seeds, is one of those subjects on which much difference of opinion exists; for we often see a successful result from two causes, widely differing from each other in their origin; and the sowing of seeds by hand is often done in a manner diametrically opposite to that in which nature performs the same operation. The latter mode is simple enough. Seeds ripening in the summer or autumn of each year sow themselves, and either fall on, or are scattered over the ground at the time when its extreme dryness precludes the chance of its vegetating then; even if it did, the hardness at the top would prevent it obtaining nourishment there. But many seeds that ripen in summer do not grow until the following spring, even when they fall on ground apparently favorable to their growth. This wise provision of nature prevents the plant vegetating at a time when it is sure to perish by the weather likely to follow. This is one of nature's modes of sowing seeds: let us see how far we imitate it.

That of many of our garden products, whose origin, if not tropical, are certainly from a more temperate region than ours, *Scarlet Runner Beans* are large, and apparently robust seeds, yet they will perish if placed in cold, damp earth. Other seeds are similarly influenced by the same causes, in proportion to their capabilities.

But many of our garden vegetables are either indigenous plants improved, or plants from those parts of the continent different but little from us in the general conditions which regulate the growth and well-being of the plant. Carrots, celery, the whole of the cabbage tribe, and various other plants, are only improvements on seeds of an unpromising description; and, consequently, their seeds are more hardy than others. True it is that carrot seed sown too soon perishes in the seed leaf, but this is often from the attacks of insects, and, after all, it is likely we sow carrot seed earlier than it would be done if left in a state of nature; for the seed does not easily part from the stem, and if left alone would, in all probability, hang until the proper time for its dispersion by the wind, or other causes; whereas, in an artificial condition, it is cut and harvested; on this point we, therefore, see the difference there often may be between the natural and horticultural mode of sowing seeds, and the want of success in the latter way may be often satisfactorily accounted for, as seeds refusing to vegetate and prosper when sown at a contrary time of the year to that suited to them.

In regard to the depth seeds ought to be buried, there is much difference of opinion; but the general rule of covering them with an amount of earth, five or six times their own thickness, is on the whole a correct one for everything sown in an artificial way, as almost all garden seeds are. Beans and Peas may be even deeper than that; but seed coming up with weak cotyledons, as carrots, can scarcely be covered too lightly. In fact, they would do without any covering, if we could depend on the seeds remaining on the ground undisturbed. Radishes are a robust crop, and will bear as much covering as *Kidney Beans*, which are much larger seeds.

Sowing thickly or thinly on the ground is not so important an object, as the after treatment of the crop. Many seeds are so plentiful and cheap, that a little extra seed is not a serious affair. But the welfare of most crops depends on their being immediately thinned as soon as they can be handled. Where this is impracticable, do not sow too thickly, for the greater part of crops are the better by not being too thick on the ground.

II.

Potatoes in the Darjeeling District.

The seed that was imported last year by Government has now been distributed amongst the planters and others, throughout the district. The variety on the whole seems to be pretty good, and will improve the quality of the potatoes in the district immensely. This year Government planted this seed first, to ascertain the most suitable way of planting them. Their recommendation is, to plant them in September, and again, in March; should this mode be carried out many years in succession, this new seed will be found to deteriorate considerably; and in all probability be lost sight of in a very few years. Experience tells us, that it is impossible to get two crops of really good potatoes in one season. But, to plant good seed in September, one can rely on a good out-turn, and if these same seed be planted again in March, the quality is very inferior, so much so, that a really good eating potato never can be got from them after.

The elevation recommended is 4,500 feet; this is all very well; we have good potato fields at 6,000 feet, and we have good ones in the plains, so it is impossible to know the most suitable elevation for a potato. The cost has been very large to Government by all accounts, and in their letter they admit it has cost them thirty rupees per maund. And as the same seed can be bought in England at eighteen shillings per maund, there must have been some oversight on the part of those who had a dealing in this matter, to allow the cost of transit to be so heavy.

NATIVE AGRICULTURAL EXPERIMENTS.

(Continued from page 290.)

Experiments towards the introduction of improved implements.

1. PLOUGHS.

I have purchased this year, from the Madras and Cawnpore Government Farms, a number of ploughs, and experimented both in wet and dry lands towards their introduction in this locality.

1. NAWAB PLOUGH.

This plough I purchased from the Cawnpore Government Farms, it resembles the country plough, consists of the working parts made of iron in the improved fashion, having mould-board and share, so as to loosen and at the same time invert the soil, and to this working part, an upright handle, and a rigid beam, to which the cattle is yoked, are attached. This plough is very light, weighing only 22lbs., costs Rs. 6. It can be conveniently carried on the shoulder ; moreover, the management of this plough requires only a little more intelligence and special instruction on the part of the ploughman ; it ploughs in the wet land, about ½ of an acre to a depth of 4 to 5 inches, in a day of 6 hours.

This plough, I think, can be best substituted for the country plough in the wet lands.

2. KAIZAR PLOUGH.

I have purchased this plough also from the Cawnpore Government Farms ; it is constructed after the model of the light American combined plough, has no wheel or coulter, and is attached to the yoke by a rope fastened to the ring at the end of the beam, is very light, weighing only 28lbs., costs Rs. 6. The adjustment of this plough is rather difficult on the part of the ploughman here. It ploughs about ¼ of an acre in friable soils, but in clayey, wet lands fails to work.

3. THE LIGHT AMERICAN COMBINED PLOUGH.

I purchased two samples of this kind, one with an upright mould-board, and the other with somewhat elongated mould-board.

The one with an upright mould-board weighes 48lbs., costs Rs. 9, fails to work in clayey, wet lands, but works in loose, friable soils.

The other weighs 56lbs., costs Rs. 12, works tolerably with the ordinary cattle in wet lands, as well as in dry lands, but however the draught is not less to the light iron plough, and at the same time the work done is not so good as that done by the light iron ploughs.

4. LIGHT SWEDISH PLOUGH WITH ONE STILT.

This plough is an iron plough manufactured in the Madras Government Farm after the Swedish model, weighs 72lbs., costs Rs. 20. This plough works well with somewhat better breeds of cattle both in dry and wet lands. It ploughs in the wet lands about ½ of an acre, to a depth of 6 to 8 inches, and in dry lands more than ½ an acre in a day of 6 hours.

I have also purchased 3 more sample ploughs from the Madras Government Farms, one of which is a large Swedish plough, and the other two B. F. I. of Ransome's Head and Jefferies, but as I have received them long after the ploughing season, I have not experimented them as to their utility in this locality.

II. REAPING KNIFE.

The reaping knife used here in cutting down the ripe paddy plants, &c., is in the form of a semi-circular arch having serrated edges, is very light, weighing only ¾ lbs. with the handle. Therefore the plants are cut down by the expense of much force, by the aid of serration in the edge ; moreover, the knife in cutting the plants jerks and gets higher, and catches only a very few plants. A large portion of the straw is thus left waste in the fields in the form of stublets.

I purchased from the Madras Government Farm a sample knife which has the form of a curve at the base and lengthened at the apex.

This knife is heavier weighing 1½lbs. It catches more plants and cuts closer to the ground. I have some knives made here of this sample, and experimented with them.

A man with this knife cuts down paddy plants in an area of ½ of an acre, leaving the stublets only to the height of 2 or 3 inches, whereas with the ordinary knife cuts down the same extent leaving the stublets to the height of 6 to 12 inches.

Coolies not being trained to handle this improved knife, some of them stupidly sometimes jerk the knife as they do with the ordinary knife, and cut the artery of their left hand, but I think if the coolies become accustomed they won't be liable to such mistakes, and the work will be facilitated.

III. WINNOWING MACHINE.

Cleaning the seed from the admixture of unfertile grains, chaff, dirt, &c., and selecting the good ones for seeding purposes, seems to be very essential, because, owing to the drought and submersion, and imperfect cultivation, a large percentage of the grain in the produce are only imperfectly developed ones, and these, when sown without separation, only the plants of a like nature germinate which die sooner or later from casualities, or yield a very inferior crop.

The ordinary process of winnowing followed here is the exposing the seeds to the wind, which operation effects only an imperfect separation and is very precarious

The process of separation by the wicker-works called Moram and Salladi, made of bamboo slippers, cleans the seed well from the admixture of unfertile grains, dirt, &c. This process, however, being very slow and tedious, is only used by women in husking the paddy.

In May last I applied to the Madras Government Farm for a sample of the winnowing machine. The then superintendent replied that the Government didn't allow the manufacture and sale of the implements and tools in the Government Farm. I then applied to the Cawnpore Government Farm for a sample of the winnowing machine and obtained from thence a machine at a cost of Rs. 30.

I experimented and found that by the assistance of this machine 3 men clean about 40 kulums of seeds in a day of 8 hours' work, but a complete separation of the seeds from the impurities is not effected in a single process, and it requires to repeat the process more than once. Moreover, the working of this machine requires the application of great force on the part of the workmen.

In January last I again purchased from the Madras Government Farms a winnowing machine of Dray Taylor & Co., London, for Rs. 80.

I experimented and found that by this machine 3 men clean about 80 kulums of paddy seeds in a day of 8 hours' work. A complete separation from the impurities is effected in a single process.

As to the amount of advantages in the selection of seeds for seeding purposes, I have not experimented this year, as I have received these machines long after the sowing season.

CATTLE.

I am thoroughly convinced as to the vital importance of keeping the cattle under my direct management by the results of the experiments I have made in my experimental village.

Throughout the year a regular shed against the inclemency of the weather, good and wholesome food, containing all the essential ingredients, sanitary arrangement, and medical assistance, are all indispensable requisites for the well-being of the cattle.

Under the present state of circumstances, none of these the cattle could get from the Porakudies, because—

1. Merasdars invariably employ other coolies in conducting the harvest, who cut the ripe paddy plants close to the ear, leaving a large portion of the straw in the form of stublets. Again these Porakudies during the period of their own starvation, sell for their food whatever they have in their hand, and leave the cattle miserably to starve and die.

2. The Porakudies who are so ignorant as not to feel the want of proper sheds for themselves, can never be expected to provide sheds for the cattle under their charge.

3. It is impossible to inculcate the principles of sanitation and proper medical aid to the semi-savage Porakudies, and I think if the Merasdars could restrain themselves from giving the cattle to the Porakudies, it will materially improve the sanitation of the miserable Porakudies themselves.

Therefore, if the Merasdars pay a little attention at the time of harvest, and cut the plants closer to the ground and preserved them without giving into the hands of the Porakudies, sufficiency of straw can be had throughout the year.

A little additional experience in purchasing the oil-cake bran, or inferior food-grains, &c., to form an admixture to the general food, he paddy straw will not come oven to the sum of money which the Merasdars annually give, for the purchase of the cattle, or *Mattu Varagum*.

The erection of permanent buildings for the cattle, of course, involves considerable expense on the part of the Merasdars, but however, this would never exceed two years' cattle purchase money, and the Merasdars can conveniently afford to have a portion of their capital laid out in the construction of permanent sheds for the cattle.

The following table shows the account of the cattle for the villages of Aroon and Thathangoody for the year 1880-81 :—

The number and valuation of the cattle on the 30th June 1880.		The number and valuation of the cattle died during the year.		The number and valuation of the cattle purchased during the year.		The total cost of feed, attendance &c. of the cattle during the year.	The number and valuation of the cattle sold during the year.		The number and valuation of the cattle on the 30th June 1881.		The value of the manure obtained during the year.
	Rs. A. P.		Rs. A. P.		Rs. A. P.	Rs. A. P.				Rs. A. P.	Rs A. P
87	625 0 0	7	78 12 0	12	250 4 0	536 1 0	...	...	12	640 0 0	50 0 0

The above account is ledgered as follows :—

CATTLE.

Dr.				*Cr.*	
To valuation on 30th June 1880	... 625 0 0		By valuation on 30th June 1881	... 640 0 0	
„ food, attendance, &c.	536 0 0		„ the number sold	.. ...	
„ number purchased	250 0 0		„ Manure	... 50 0 0	
„ „ died	... 78 0 0		„ Balance	. 795 1 0	
Total	... 1,485 1 0		Total	.. 1,485 1 0	

The total cost of cattle keep for the year 1880-81, for both the villages, is Rs. 795-1, and the yearly expense under the Porakudi system for the past 13 years, as given in the table, amounted to more than Rs. 450 besides the Varum.

In the year 1880-81 out of 42 bullocks, 12 bullocks were employed in ploughing by light improved ploughs, cutting and other purposes, and their extended labour reduces their cost of keep very much.

In the Arachoors Bingah of my estate, which consists of 4 full villages, extending about 1,000 acres, and situated within 3 miles from my residence, I refused to sanction money for the cattle purchased, and purchased the cattle myself, to make up the number lost by death, and kept a portion of them under my direct management, and gave the rest to the Porakudies.

I allowed to those Porakudies whom I permitted to carry on the cultivation operations with the cattle under my management, all their inams and wages, as usual on the Porakudi system, excluding the straw.

Thus, for the year 1879-80 I had about 150 cattle under any direct management, and for the year 1880-81, their number was increased to about 250, and as a consequent result, the mortality of the cattle under my management is greatly reduced, while in those of the Porakudies ranged in the usual percentage.

Moreover, the working capability and valuation increased in the same way, while in those of the Porakudies decreased.

It suggests to me that the institution of the Government Farm and School of Agriculture in Madras, may perhaps be an ample means for the diffusion of sound agricultural principles abroad in the country, if the agricultural people be properly educated.

Most of the people engaged in agriculture in this country are scarcely able to understand what the Farm Institution is doing for the improvement of the country.

Moreover, they are so governed by custom, habits, and religion, that any step towards the improvement seems to them incomprehensible and impossible.

Therefore, I am of opinion, that the desired effects of the institution of the Government Farm and Agricultural College in Madras will only be produced, if Government Farms be opened in the districts, and placed under the charge of students trained in the institution, who will be able to conduct experiments and demonstrate the benefits arising from the adoption of rational principles of agriculture; get, and supply the necessary improved implements, and train men practically for engagement under large landholders, &c.

2ndly. The chief difficulty in bringing about changes, in the agricultural practices of the country, lies in the unwillingness of the Porakudies. The object of rational agriculture being to economize labour, the Porakudies are afraid that they will be thrown out of service, and oppose the introduction of salutary changes. In such cases, the Merasdars are obliged to dismiss them, and also to eject them, which, however, they cannot do without the intervention of Civil Courts. The procedure is costly, and the delay long and unavoidable. The best course would be to invest the Collectors of the Districts, as before, with summary powers to inquire into such cases, and eject the Porakudies, without putting the Merasdars to inconveniences, and pecuniary losses.

KRISHNA SAWMY MOODELLIAR,

V STREEVAS ZAR, Agricultural Manager.

EXPERIMENTS IN THE SHAHJEHANPUR DISTRICT.

(By Pundit Ajudia Prosad.)

DURING the course of the last year, your department sent me seeds of different kinds for experimental cultivation in my farms. Each particular kind was accompanied by a request asking me to report the result of the trial. As it would be a rather tedious and lengthy task for me to report the result of each separately, I hope I would be forgiven the liberty I have taken in submitting the results of all in one report.

This report may be divided into the following different heads.

I. Grain. (a) Indigenous. (b) Foreign.
II Roots. (a) do. (b) do
III. Vegetables.
IV. Fodder crops.
V. Cultivation of things which do not, properly speaking, fall under any of the preceding heads
VI. Miscellaneous remarks.

I. The cultivation of grain can be classified under two general heads, *kharif* and *rabi*. I treat of each of these separately.

Different kinds of rice were sown in the former season, but owing to the want of grain no good results were obtained. Although there was some outturn, still on comparing with that of better and former years, it was merely insignificant. There would have been a difficulty in obtaining even this little had not the Assamees wisely listened to my proposal of throwing *kacha* dams across the Gomtee, which enabled them to water their rice in the severe and protracted drought, and thus to ensure a meagre rice harvest in the Indalpur Gomtee valley. This laudable example was, I am glad to say, followed by the other copar in villages in the vicinity, and they also were rewarded with a shadow of success.

Of the remaining *kharif* grains the result was rather better, though not equalling that of past years. The reason for this is that these grains do not require so much of water as rice, and so the drought did not have so baneful an effect upon them. In addition to this, it may as well be stated that this part of the district is peculiarly suited to *til*, *bajra*, *mong*, &c. No or very little crops having been obtained towards Tilhar and Shahjehanpur, *Juar* is not generally cultivated here, but as I stated in my report last year, I tried it and experimented with nearly forty beeghas of land. The result was, I am sorry to say, very bad. This may in a greater part be attributed to want of rain. To remove this doubt, I intend giving it another trial this season.

Of foreign *kharif* corn only maize was tried on my farms with seed received from the Agricultural Department. I was apprised

by Circular 6A of that department of the despatch of five kinds of American maize to my address. The names of those are :—

(*a*) Golden dent corn.
(*b*) Adams extra early corn.
(*c*) White flint corn.
(*d*) Yellow Canada corn.
(*e*) Tuscarora corn.

By some mistake only 3 kinds reached me, two bags containing Canada corn and Tuscarora corn having been replaced by bags of two of the other varieties. Two kinds of Jaunpur maize were also received by me. All this grain was distributed equally to four of my farms, *viz.*, at Indalpur, Hetinagar, Doondwo, and Karkya. The American maize occupied 36 beeghas of land in all the above farms, but unfortunately it did not germinate all well, only a few struggling plants being found here and there. This miserable little number of plants even was not destined to prosper, as rats immediately attacked it, and many were eaten up root and all. Seeing the fate the remainder were likely to suffer, in farm No. 2, I got them transplanted, and they were then watered nearly six times. They thus yielded a few seers of seed, which was not as good as the original. In the other three farms the plants were allowed to remain in the same fields, they received every care and were weeded, but did not produce any crop. The two kinds of Jaunpur maize was tried over nearly 30 beeghas in all the four farms, just after germinating, the plants were very healthy and promising, and remained so up to the time they flowered. But immediately the flowers appeared, the plants were attacked by myriads of large insects with black wings, who ate up the flowers and also the hairy flocks of the cobs. Thus no grain was formed in the cobs generally except in a very few instances, which have been very carefully preserved.

In the *rabi* season no foreign seeds were tried, and the South Australian wheat was given up owing to the many and successive failures which occurred in attempting it. Country wheat was tried largely as usual in all the farms. In this part generally Katha wheat is sown, which is small, hard and red in colour. I got two superior country kinds called Samharea and Moondea, the latter so-called because its ears are void of whiskers. These two kinds are large, soft and white, and are in every respect better than Katha wheat. The respective average produce obtained from each of the three kinds is herewith given. The average outturn obtained from Katha wheat is 1 maund 7 seers per beegha, that from Moondea is the same, whereas that from Samharea wheat is 1 maund 13 seers. These fields were not watered ; my object was to find the wheat which with ordinary culture would pay best. I accordingly proceeded entirely on the native plan, and am glad to say that Samharea wheat is the species which has appeared to me best hitherto.

Gram was a total failure this year. It did not germinate nicely, in the first place owing to the dryness of the land and yielded very poor crops in a few places, but such spots are rare.

Barley and Gojae, though not equalling preceding years, were, seeing the other *rabi* crops, tolerably good. It may here be not out of place for me to state a fact which shows the immense advantages upon which a cultivator can surely calculate if he uses the light English plough Kaisar. I tried Barley in 22 beeghas of land worked with the native plough ; the outturn was very wretched indeed, an average of 20 seers per beegha only being obtained. A little plot of three beeghas of similar soil was worked with the Kaisar in the rains and then sown with barley. Both the plots were exactly similar, and an uniformity of condition was maintained between them as far as practicable. The outturn from this latter field amounted on the average to 2 maunds per beegha. Thus the result of the experiment is another addition to the already numerous proofs obtained which show the decided superiority of the Kaisar over the native ploughs.

II.—Roots (*a*) Indigenous.

Carrots were tried on a plot of land which received manure at the rate of ten maunds per beegha. This manure was prepared, as I last year stated in my report, by storing up cow-dung mixed up with cattle urine and dead leaves. The field besides received five waterings. The outturn amounted on the average to 2 maunds per beegha. The liberal outturn which this crop gives as well as the comparative ease with which it can be cultivated together with the good stead in which it stood to people in the last two years of drought, has, I am glad to say, stimulated many cultivators here to try it largely. There was, and still exists to some extent, a prejudice among the higher classes of Hindus against eating carrots, because its Hindi name Gajar (*Gajar*) commences with the letter Ga (*Ga*) which is also the commencing letter of the word Gai (*Gai*) cow. This prejudice is gradually giving way, and leads men to expect that in time it will be totally erased. Onions were tried experimentally as a field crop in a plot of land which was manured just like the carrot field, but received only two waterings. The outturn amounted to 3 maunds per beegha. In this part the climate appears suited to its cultivation and as a small quantity of seed gives large crops, I should strongly recommend its trial. The people here with the exception of Hurdea, Moroos, and malees, are prejudiced against its cultivation. The Hindoos generally do not eat it, and consider it unholy.

Turnips.—Some turnips were tried by me as a garden crop, and yielded very fine roots. The people are generally prejudiced against eating and sowing them as against onion.

Turmeric.—I tried turmeric in a plot of land this year. The average outturn amounted to 3 maunds per beegah, the roots being weighed just after being dug out of the ground and washed. This, I am told, is not a very good return as turmeric yields an outturn nearly equal to carrot. I wanted much to try it largely, but unfortunately here the prejudices of my countrymen stood rather awkwardly in my way. It may not be out of place for me to describe the prejudices which prevail in this part of the country, and I believe all over the N.W.P. about cultivating this root. It is used in almost every Hindoo worship, and when mixed with lime forms the red substance which is applied to the forehead (roli). Here no class of people whatever will ever cultivate this thing except the particular class of Moroos termed Hurdeas who derive their name from the Hindi word (hurdea) turmeric. The Moroos will never sell the seed tubers as they consider it unlucky, and likely to result in the death of their families or some other misfortune. If any one of their class comes to a village and chances to have no seed, they all give him a little, and with that he commences business, and is in two or three years enabled to gather seed enough. Besides these Moroos, other people consider it unlucky even to sow the seed into the ground for another man. My *malee's* answer was characteristic when I asked him to sow for me last year—"Neither my father ever did so, nor my grandfather before him, and I will also never do so even if you dismiss me." Should any Moroos other than Hurdea, ever cultivate it, his caste people would ex-communicate him. This prejudice does not prevail towards Pallia in the extreme north of the district, and the lands beyond the Gogra in the Lukhimpore district in Oudh. There, every class of people and almost every cultivator cultivate it as a field crop. They prepare the land just as it is prepared here for the sugar-cane, and when it is ready to receive seed, two ploughs go in front, and a man walking behind, lays the tubers in the furrow, about a foot apart. The field is then harrowed. When the plants grow up, they are weeded twice. If the rains are favourable, no irrigation is necessary. This crop needs no watching as, owing to the peculiar smell and taste of the leaves, no animal will graze them. The tubers when they are boiled and dried form the *huldee* of commerce. Those which are kept for seed are stored up in a pit dug in moist ground, and are taken out only when about to be sown. Seeing the comparative ease with which this can be cultivated, and the good outturn which it yields, I can safely recommend its cultivation to every cultivator. The seed tubers which are sown do not rot, but remain adhering to the end of the stem. The Moroo cultivators separate it from the stem when weeding the field, and those who try turmeric largely, separate it when they dig the crops out of the ground. These seed tubers are sold to the cloth dyers (*rungrej*) who use it in dyeing cloth.

(*b*) Foreign roots.

Ground Nut.—I tried a little of this from seed received from the Agricultural Department. The climate seems favorable, and I have, I am glad to say, succeeded in getting seed enough for the next year. The rats did it great injury. The produce does not equal the original in quality.

Mangold Wurzel.—I received through the Director, Department of Agriculture, six seers of seed of two species of this root. I

tried it largely as a field crop, but owing to some defect in the seed, it did not germinate properly—only a few stray plants came up here and there. These were properly taken care of, and yielded roots not at all inferior to those exhibited at the late Lucknow Exhibition. Some which were weighed were nearly five seers. I tried to make seed but could not succeed. I may as well remark that the leaves of mangold wurzel are fit to be eaten by the poor classes as vegetable, so it will not simply be a fodder crop, but will help poor people greatly in times of scarcity.

Carrot.—Two kinds of carrot seed were received from the Department of Agriculture. The seed came rather late, so that it was sowed fully one month and-a-half after the country kinds. The produce was, therefore, less than that of the latter by six maunds per beegah. I am sure the results would have been equal had the English species been sown as early as the country one. I should, therefore, strongly recommend an early supply of seed. The roots of the English kind were larger and better flowered than those of the country kind, and were much liked by the Moroos and other cultivators, who wish to try them. I am going to supply them with a little seed next season.

III.—Vegetables.

Cauliflower.—I stated in my report last year that the Moroos and other cultivators here hold that the climate of the locality is not suited to cauliflower. I gave it a trial last year and succeeded. This year my success has been a special one; large flower heads were produced which were exceedingly well flowered, and were no way inferior to those raised at Shajehanpore. In order to know whether they would ensure a sale in the market, I sent some there; these were eagerly purchased. This fact, I am sure, will stimulate Moroos to try its cultivation.

Cabbages.—I got some cabbage seed through the Agricultural Department, and tried it here. This was entirely a new experiment. I am glad to say I was rewarded with success; the heads were exceedingly large and pleasant to the taste. Natives are generally prejudiced against using it, but as I had a very large quantity I used up as much as I could and sent some to the market, where it fetched a high price. I am sure this will be a very good industry for the Moroos and other vegetable cultivators. I tried to make some seed, and have succeeded in getting a very small quantity, the productive capabilities of which, as compared those of the imported seed, I will try next year. The Moroos want seed, and I will let them have some.

Pumpkin.—Mr. Stoke of Shahjehanpore very kindly procured me a few long pumpkin seeds from Azimgurh. I sowed them here along my garden wall, and when the plants came up trained them so that they spread on the wall. They fruited immensely and for a very long time. The majority of the pumpkins produced here were about four feet long. This would no doubt be a great help to the poor classes when corn fails, as the plant requires but little care and continues to afford food for a time longer than the pumpkins cultivated here. I have got a very large quantity of seed which I will distribute freely this year.

IV.—Fodder Crops.

Reana.—The present was my second trial of this fodder, but I had no better luck this time than last year. I am disposed to think that this would do as a garden crop, but is unfit for the field, as it requires very careful treatment, and is very delicate.

Sorgho.—I got 20 seers of sorgho seed from the Department of Agriculture last year, and I tried it here in two places. The plants were healthy and juicy. The general cultivators here do not prefer it to their own chari, as they urge that their own kind affords fodder for their cattle during the winter months, and also supplies them with grain to some extent. The sorgho grain on the other hand is bitter. I, however, prefer it owing to the peculiar property of fattening animals, and increasing the quantity and quality of milk in them. I have besides another point in view. At the late Lucknow exhibition, I saw a sample of sorgho *rab* exhibited by Mr. Harrison of the Agricultural Department. I am going to try to press sorgho juice and make *rab* from it. If I succeed, I am sure sorgho will be adopted almost universally by the cultivators here.

Lucerne.—I received some seed from the Agricultural Department, and tried it. As regards the quality of enriching the soil this grass is said to possess, I cannot give any opinion just now, but hope to be able to do so next year after sowing some crop in the plot lately occupied by the grass. As regards the utility of this as a winter fodder, I agree, but at the same time I can safely say that though it may do for large farmers and big landed proprietors to attempt it, still for an ordinary cultivator it would never do.

Fodder crops are, as a rule, only useful in places where pasture is scarce. This part of the Shahjehanpore district, namely, the Khotar pergunnah, abounds in jungles, and consequently in rich grazing lands. Fodder crops, therefore, unless they possess some peculiar advantage, or require little or no labor in raising them, can never be adopted by the cultivators generally. These crops, specially sorgho, will be an invaluable boon towards Tilhar, Katra, and Jellalabad, where there are no grazing lands.

V.—Under this head I have to treat of four things:—

Sugarcane, Tobacco, Cotton, and Inga Dulces.

Sugarcane.—Hitherto, for the last six years my farming career was nothing, somehow or other, but a series of failures. This time, however, in sugarcane I have, I am glad to say, to boast of something having the semblance of success. I tried 48 beeghas of sugarcane in my three farms last year.

Farm No. 1	...	...	20 beeghas.
Do. " 2	...	...	18 "
Do. " 4	...	...	10 "

Of these three farms the sugarcane of Nos. 1 and 2 was pressed by the two Behea Sugar Mills purchased from the Agricultural Department. In both of these farms, the quantity of juice pressed amounted to 20 tirhas. A tirha means 13 matas, which latter is an earthen pot of about three-and-a-half maunds capacity. In working the native kolha night and day, the following number of men are required:—

2 Pindhas (men who beat the cane-bits into the mill with mallets).

2 Mothas (boys who supply handfuls of cane bits to the mill.)

2 Jhokhas (firemen who feed the furnace and regulate heat.)

These laborers are paid in juice which they convert into *rab* or goor and sell for themselves. The rule being that in each tirha after pressing twelve matas for the master, they take the thirteenth to themselves, and partition it among themselves, according to the rate given below. The Pindhas get half, and the Mothhas and Jhokhas divide the remaining half equally among themselves.

In working the Behea Mills, Pindha is not required, and his share goes to the master. I arranged with the laborers in a different way, and paid them one rupee cash for each tirha, which they distributed among themselves. I should here like to show the profit I obtained by using the Behea Mills in pressing my cane instead of employing kolhus.

All the juice pressed by the Behea Mills amounted to 20 tirhas as I said before, and for each tirha, one rupee was paid to the mill laborers, thus:—

	Rs.	As.	P.
Amount paid to laborer for pressing 20 tirhas	20	0	0
Oil, for oiling the mills	0	4	0
Total ...	20	4	0

In using the native kolhu, as I stated before, for every 12 matas, one mata of juice is given to the laborers, each mata yields 20 seers of rab worth Rs. 2 on boiling, thus—

	Rs.	As.	P.
For pressing 20 tirhas, 20 matas ought to have been paid to the laborers, and these were worth ...	40	0	0
To carpenter for looking after the kolhus and keeping them in repair ...	6	0	0
Khundwree or chopping sugarcane into bits @ 1 anna per diem	5	0	0
Total ...	51	0	0

Taking away 20 rupees, 4 annas from Rs. 51, the saving obtained by using the Behea Mills simply in the labor wages is Rs. 30

12 annas. But the juice pressed by the Behea Mill gives an excess of 5 seers of rab, worth 4 annas per mate. Therefore, for each tirha the excess is worth $\frac{13 \times 4 \text{ Rs.}}{16} = 3$ Rs. 4 annas, and for twenty mates this becomes Rs. 65; adding this to the saving in labor, the total profit on the Behea Mills is Rs. 95,12 annas, and therefore on each mill singly it amounts to Rs. 47,14 annas. I this time experimented upon the respective working rates of both the Behea and the country mills, yoking bullocks of average strength to both. It was found that the Behea Mills could with ease press 6 mates of juice in night and day, and if worked hard could turn out 7 mates. On the other hand, the kolhu when worked extremely hard could not produce in that time more than four, whereas at an easy rate of working 3 mates were all that could be expected.

I should now like to touch briefly on the difficulties I met with in manufacturing rab, and should be extremely thankful if any remedy could be pointed out:—1st. There is generally a great difficulty in procuring cane enough to supply the Behea Mills, as the working rate being very fast. I find a difficulty in getting men enough to cut the cane in the field, to scrape and clean each individual stalk, as well as to remove the crown top. If there is any machine which could scrape the cane and separate the leaves quicker, and at the same time be of a moderate cost, I am sure it would be adopted very generally and would be a great boon to the cultivator.

2nd. After pressing the juice, boiling it is another great difficulty, owing to the rude pan used here. This pan is made of circular bits of iron clumsily soldered together. The space between the edges of these is not quite closed and constantly leaks, to prevent which (chorousee) a mixture of ord flour, bael fruit and chopped flax is applied over the parts leaking. This prevents leakage for the time being, but the leak is liable to spring up a new. If it springs up, as it generally does when the juice is in the pan, the loss can be easily conceived; I myself this year having lost about 6 maunds of rab owing to this leaking. If any better kind of pan could be introduced, I am sure these difficulties could be removed. I saw the pan invented by Messrs. Thompson and Mylne, of Behea, at the Lucknow Exhibition, but that sort of thing would never do for a man working on a large scale, a s it is too shallow; we want something which will boil at least 4 maunds of juice at a time. In cleaning juice I could not, I am sorry this year, use lime and clay as prescribed by the Agricultural Department, but I tried some of the native receipes, which are wild sorrel, buttoa grass, castor seed, and buttermilk. These things are thrown into the pan when the juice swells up and the rab is on the point of being formed. Half a chittack of each of the first three is used in cleaning 4 maunds of juice, while of the last one seer is required for the same quantity of uice.

Tobacco.—Of this seed of three kinds, *vi*., White stem, Oronoko and Connecticut was received by me. Half the seed of each kind was tried in Farm No. 3, where it somehow failed to germinate, the remaining half was kept for some time and was then sown. It yielded a crop, and a good deal of seed has been raised which will be distributed among the Moioos who like it exceedingly. The leaf will be cured for the native market.

Inga Dulces.—Two seers of seed was received from the Agricultural Department. It was sown in Farms Nos. 1 and 3. It germinated, but owing to severe illness prevalent in the village in which Farm No. 3 is situate, no proper care was taken of them and almost all died. Some trees in Farm No. 1 are living and are flourishing. These trees will make a good hedge, and would be useful in gardens, but here in the field they would be of little use.

Cotton.—As I stated in my report last year that people in these parts think that cotton cultivation never succeeds here, so I determined to test the truth of this belief of theirs, and tried cotton in four farms of mine. Country cotton was tried as well as three of the foreign kind of which seed was received from the Agricultural Department. Generally very rich land was chosen everywhere for the experiment. In Farm No. 1 country cotton failed entirely as well as the Egyptian cotton. Bamiah, New Orleans and Upland Georgian were the only two that succeeded. A table showing the outturn of cotton without seed obtained per acre in all the different farms is subjoined below.

Farm.	New Orleans in lb per acre.	Upland Georgian in lb per acre.	Bamiah in lb per acre.	Country cotton in lb per acre.
Farm No. 1 ...	82·12	41·25	Nil.	Nil.
" " 2 ...	292 12	211·25	Nil.	Nil.
" " 3 ...	Nil.	Nil.	Nil.	86·00
" " 4 ...	168·75	83·50	Nil.	156·50

Bamiah failed entirely everywhere, no outturn was obtained, only a few plants in each farm yielded a little which was yellow and bad looking. New Orleans appears to be the best. It has, as the table shows, not only surpassed all the remaining imported varieties, but the country one also. Farms Nos. 2 and 4 have done the best, the reason being that in the former the experiment was tried on a flat of exceedingly rich gowhanee land, whereas in the latter an old cattle compound which had been tenanted by cattle for about 20 years and was lying vacant for nearly the last six, was the area experimented upon. I am no doubt sure that New Orleans and Upland Georgian cottons are better than the country kind for the following reasons:—

1stly.—In these two varieties, every five seers of produce obtained from the field yields 1 seer 12 chittacks of cotton and 3 seers 4 chittacks of seed, whereas an equal weight of unginned country cotton will yield only 1 seer 8 chittacks of pure cotton and 3 seers 8 chittacks of seed. Thus there is an increase of 4 chittacks of cotton in every five seers.

2ndly.—The American kinds possess the great advantage of yielding a crop in the second year too. I have allowed the plants to remain, and they are now laden with flowers and pods which foretell a good harvest presently. The village people talk of cultivating these varieties, and I have promised to supply them with seed.

The cotton dressers (Behuas) complain that they find it very difficult to separate the seed of these two varieties from the cotton, as the fibres being larger and softer than those of country cotton, do not pass out easily between the rollers of the gin, but get wrapped round them. This is surely a great difficulty, but can easily be removed if a better sort of gin could be obtained.

II. Under this head I shall treat of two things—(*a*) irrigation: (*b*) cattle.

Irrigation.—Six years' experience as a farmer has shown to me clearly that cultivation can never succeed unless there be an ample supply of water with which to irrigate fields. Deep ploughing and manuring, though exceedingly beneficial in the presence of water, are comparatively of little or no use when that general solvent is not present. People generally assert, and I concur with them, that no kind of water is so useful to crops as well water. The reason for this in my opinion is, that well water contains in solution a great deal of mineral substances taken from the different strata with which it came in contact while percolating through the mass of ground. In sugarcane cultivation specially, people say it is impossible to get a first rate crop without the application of well water, although there may be an abundance of river or tank water. The difficulty of obtaining well water is particularly felt in these parts of the Shahjehanpore district, *viz.*, the Pewayan and Khotar Pergunnahs, owing to the sandy nature of the subsoil and the absence of a solid stratum (Nagasan) which renders it difficult to sink *kutcha* wells. I myself once saw a painful sight. Three brothers were making a *kutcha* well near their sugarcane field, one was inside excavating mud, while two from above were drawing it up in baskets. All of a sudden the earth in which the excavation was made sank down and covered the man who was underneath. One of his brothers went in to assist him and the mud falling in for the second time covered him too. One of these two poor men died and the other was saved, though severely hurt. Besides the danger with which making *kutcha* well is here thus attended, it often disheartens and ruins the poorer class of cultivators. Sugarcane is a crop on which cultivators almost entirely build their hopes, and if to irrigate such a field a man tries to sink a *kutcha* well, and if, as often happens,

fails in two or three attempts, he being a poor man can persevere no longer and his crop is ruined. The construction of *pucca* wells would remove this difficulty entirely. I am making one in farm No. 1, but this will not be able to supply even the whole of the farm with water, not to talk of the whole village.

Cattle.— I had collected nearly two hundred cows to improve the breed of cattle, and feeling the want of a bull of superior breed, asked the Department of [illegible]ture and Commerce to supply me with one, which it ve[illegible] supplied me in February last. I heard from gentlemen [illegible]o had experience with regard to these bulls that they did [illegible]ve cows when brought to these parts. I am glad to say that [illegible] adopted a peculiar plan with the bull, in virtue of which he has up to the present served more than twenty-five cows. I have freed him from all restraint, and let him go loose among semi-wild kine. The result is that it is in exceedingly good health. Seeing that powerful animals were required to work the kaisar plough and the Behea Sugar Mills, as well as to drag garries, I collected twenty buffaloes, and their male young ones I employ in doing the above works.

In these parts cattle are subject to a peculiar disease called (*joak janna*) in which the animal suffering gets a lot of leeches (*jonk*) inside his stomach which injure him and ultimately cause his death. This distemper makes dreadful havoc in the herds of cattle. I myself lost this year nearly 60 cattle owing to it. Besides the above, the hoof and mouth disease prevalent everywhere in India do immense injury to owners of cattle by destroying their animals. Could any remedy be prescribed for the above diseases, I am sure they would be a blessing to the people here.

EDITORIAL NOTES.

A RECENT return from the Officiating Secretary to the Chief Commissioner, British Burmah, gives a mass of interesting information regarding the material progress being made by that comparatively young province. The late census having upset all preconceived ideas of proportions, the population is found to be much larger than was supposed, and the returns, hitherto accepted, of cultivated area are about 15 per cent. below the truth. These discoveries necessitated a revision of the statistics of the province. The following may now be accepted as pretty near the truth.—

Population, about	...	3,700,000 people.
Total area	...	87,220 square miles.
or about	...	56,000,000 acres.
Cultivated area, about	...	3,910,000 „
Area growing rice	...	3,300,000 „
Computed total yield of paddy, or rice in husk, about	...	2,361,000 tons a year.
Average yield of paddy per acre about	...	32 baskets or bushels,
equal to	...	1,600 lbs.
Number of cattle, including buffaloes which are used largely for agriculture	...	1,453,000 head.
Number of carts	...	225,000
Mixed fruit-trees	...	130,000 acres
Danee palm (used for thatching and also for extracting sugar)		30 600 „
Tobacco	...	20,230 „
Plantains	...	17,100 „
Vegetables	...	17 000 „
Areca nut	...	14,100 „
Cotton	...	10,900 „
Pulse	...	8,000 „
Sugarcane	...	5,000 „

It is a curious commentary on the recklessness which has characterised our former dealings in timber, to be told that 80 per cent. of the timber now shipped from Burmese ports comes from outside our frontier. Cutch to the value of £200,000 is exported annually; but, notwithstanding all these, and many other industries, the report rightly adds that the cultivation of rice is the foundation on which the prosperity of Burma must rest. Mr. Hough, acting Settlement Officer under the Chief Commissioner, in looking forward to what the new Agricultural Department may be expected to accomplish, says.—

It seems to me that one of the great wants of this country is a *plough* and more especially, for these elevated and dry and hard soils which are rapidly coming under cultivation through the eagerness of the people to possess, and cultivate land. These soils, as compared with the temporarily submerged tracts are most assuredly deficient in 'lasting power,' and their capabilities will never be enough developed unless and until they are properly ploughed. There is no such thing as a *plough* in Burma. Can we not persuade the people to adopt one? I think we can. The experiment has already been attempted by myself in the Prome district, althoug certainly on a very humble scale, but, so far as it went, it was a success, and gave good hope for the future. The ploughs with which I worked were the 'Kaisar' plough and Cuick's patent plough. To introduce a suitable plough into Burma should be amongst the new Department's most earnest endeavours.

He also adds:—

In order to put the scheme into practice, the first step would appear to be the creation of an experimental farm, the managers of which shall work *amongst the people and with them*. I mean that the farm should be established in the midst of a purely agricultural community, and not within the limits of Rangoon or any other large town in the province. It would, in my opinion, be desirable to locate the farm at a spot where lands fairly representing the great classes of land in the province are easily accessible. I mean hill, upland, and plain. An abundant and constant supply of good water is also essential. A spot fulfilling all the above conditions can, I think, be found near to the town of Pegu, and the projected railway hither would place the farm within easy reach of head-quarters. The Superintendent or Director of the farm will of course be a person with previous experience in such experiments, and I would suggest that his principal native assistant be a Burman Extra-Assistant Commissioner, who shall receive extra pay for duties which will probably be at first somewhat distasteful to him. It is necessary to have in such a venture a Burman official of rank as "right-hand man." Minor assistants might at first be selected from the Veterinary Instructor's (Mr. Frost's) pupils.

This is very much to the point. Very much time and no little outlay have been wasted on the experimental farms in India from a want of anything thoroughly practical in their working. Our aims have been good, but we have signally failed to produce crops equal to those produced by the ryots, either as to quantity or quality. It may be that, instead of aiming at agriculture of a practical nature, we have made our farms more like schools and colleges. What we want is a farm which shall be worked among the people, we should follow, as far as may be, the agricultural customs of the people, improving gradually on them, and showing the surrounding farmers what can be done by slightly improved modes of cultivation. Looking at the richness of the soil of Burma, and at the generally favourable climatic conditions under which agriculture is followed, we may predict a great future for the province.

THE report on cotton cultivation in the Punjab for 1879-80 has only recently been issued, and includes what is known as the cotton year, that is, from 1st July 1879 to 30th June 1880. We cannot understand why there should be so many official years. Every department or administration seems to have its own mode of reckoning the year. For many reasons, the ordinary calendar year would do for all purposes, although the financial year, from 1st April to 31st March, is peculiarly well adapted for agricultural purposes, including as it does both crops, *rabi* and *kharif*. Over the whole province the results of cotton cultivation have been better than those of the previous year, and very much better than those of 1877-78. The following table shows the statistics for those three years.—

	Acres.	Outturn.	Per acre.	Acre Value.
		cwts.	lbs.	Rs.
1877-78	... 6[illegible]	3[illegible],180	58	11-13-10
1878-79	... 80[illegible]	6[illegible]	[illegible]	13-4-5
1879-80	... 800,420	[illegible]	[illegible]	15-0-4

This is of course cleaned cotton[illegible] although the outturn of 1879-80 was much better than [illegible] preceding years, it was very light compared with th[illegible] other countries, America,

for instance. The outturn of cotton in the Uni[illegible] States runs from 250 to 300 lbs. per acre. That this very small outturn is due to inferior modes of cultivation is proved by the fact that in many districts, and even in portions of the same district, the production was very much higher. In the Delhi division, for instance, the following results are reported :—

Gurgaon district	...	82 lbs.	per acre.
Kurnal do.	...	107	„ „
Delhi do.	...	330	„ „
Average	...	105	„ „

The lowest outturn was in the Kangra district, and this was to be expected, as the Kangra country is high and cold, compared with the other cotton districts. The faulty nature of the cultivation is proved besides by the results of certain experiments made. The out-turn of cotton is reported as having been very good. As usual the tehsils of Peshawur, Doaba Daudzai, and Hashtnaggar are stated to have yielded most largely, as a great extent of the country lying in these tehsils is 'abi' or irrigated land.

The returns as to cost of cultivation per acre are very absurd, ranging from Rs. 2-8 in the Kangra district to Rs. 42 in Ludhiana. These figures are clearly unreliable, and the vast discrepancies are doubtless caused by mistaken ideas on the part of the returning officers as to what constitutes cost of cultivation. To arrive at correct data a return should be issued with a line for every possible head of cost, and each detail should be given separately. An attempt was made to obtain correct data, and five districts made returns which are as follow :—

		Irrigated and manured.	Irrigated but not manured.	Unirrigated but manured.	Unirrigated and not manured.
		Rs. A. P.	Rs. A. P.	Rs. A. P.	Rs. A. P.
Umballa	...	37 6 6	27 12 3	25 7 0	16 1 0
Ludhiana	...	42 6 0	33 15 4	21 12 4	11 7 4
Jullundur	...	20 12 0	14 10 0	14 8 0	13 8 0
Hoshiarpore	...	33 14 0	21 7 0	13 7 0	9 10 0
Dehra Ghazi Khan	...	28 4 0	12 5 0	...	4 8 0

From this it would appear that the average cost of irrigating an acre is Rs. 12 11-1, a sum either absurdly in error, or a disgraceful over-charge. The average ruling prices in 1879-80 was Rs. 20-7-7 per cent., or 4·38*d* per lb. It is worthy of note that during the year no experiments with exotic seed were made. We presume, however, that a judicious system of interchange was tried. Exotic varieties have often been tried, but experience has shown that if we wish to excel in cotton cultivation, we must turn our attention to improving our indigenous varieties; and this can perhaps best be attained by careful selection every year, which in a few years will result in our crops being raised from what might be called pedigree seed.

The Directors of the East Indian Railway, in their report for 1880, gives some interesting details of the working of this, the first year under the new proprietary. For purposes of comparison of individual items of goods traffic, the report is not so useful, as during 1880 all materials carried on revenue account were credited to traffic, and the amounts debited to each departmental account. Thus, in the goods carried, there was an enormous increase, although, for the reason stated above, this increase was largely nominal. The following table shows this :—

			1879.	1880.
Goods carried	...	Tons	1,816,001	2,561,049
Minerals „	...	„	748,618	910,060
		Total	2,564,619	3,471,109

[illegible] per cent. The cost of carrying a [illegible] 241*d*., and the average amount [illegible] ·832*d*. The difference of goods traffic, [illegible] account materials now being charged, [illegible]

		Tons.		
		1879.	1880.	Increase.
Railway Materials	...	15,452	522,317	506,865
Coal	...	24	51,297	51,273
		15,476	573,614	558,138

Keeping out this item, th[illegible]ease in tonnage of 1880 over 1879 was 348,352, or 13·5 per cent. On the other hand, the increase in receipts fr[illegible]oods was only £1,256,719 against £1,229,471 in 1879, an [illegible]ase of £27,248, or 2·2 per cent. During the year several reductions were made in the tariff, which accounts for this apparent discrepancy. Looking at the passenger traffic, we find progress being made. The following are the numbers of passengers carried :—

			1879.	1880.	Percentage. 1880.
First	class	...	43,894	43,563	·5
Second	„	...	133,424	145,782	1·8
Intermediate	„	...	563,619	592,119	7·3
Third	„	...	7,028,184	7,300,364	90·4
	Total	...	7,769,121	8,081,828	100

This shows the value of the third class passenger. That the directors know his value, is shown by the consideration they show him. We learn from this report that they are increasing their locomotives and third class carriages, preparatory to reducing the third class rate from 3 to 2½ pies per mile. The cost of carrying a passenger one mile is ·135*d*., and the present rates are 2·25*d*., 1·125*d*., ·5625*d*., and ·3435*d*., for 1st, 2nd, intermediate and 3rd class, respectively. Owing to the preponderance of third class passengers, the average amount realized is ·375*d*., leaving a profit of ·24*d*. per mile for each passenger. This is exceedingly cheap travelling, and were it not for the large number who travel, the rate would have to be higher. The entire management of the line continues to reflect the highest credit on the officials here.

We have lost no opportunity for years of advocating the immediate construction of the through railway from Calcutta to Nagpore, by Midnapore, Sumbulpore, and Raepore. The proposal is now occupying the attention of Government, and we hope soon to see a beginning made. "The proposed railway would run from Nagpore *viâ* Raepore to Burrakur, or thereabout, and would form the much wanted missing link in the direct line of communication between Bombay and Calcutta. It would tap the Warora coal-fields, and it is calculated that the mineral traffic would compensate for the very limited passenger traffic to be expected from the sparsely populated country through which a considerable length of the line would run. Who the promoters are is not stated." This remark about the "sparsely populated country" is quite correct, but we must not run away with the idea that the line would on this account not pay. The population is scanty, it is true, but it will certainly increase when the want of communication is supplied. The soil is the finest in India, and if it is not cultivated more extensively, it is solely because of the impossibility of getting the crops to market. Three or four years ago vast tracts of ripe wheat were allowed to rot in the fields, because the cost of cutting and transporting it was more than it would have realised in the market. The distances to railway stations and other large centres of populations are so great that buyers cannot afford to purchase the grain at anything like reasonable prices. This will all be changed by a railway connecting the rich agricultural districts around Sumbulpore, and westward towards Raepore, with Calcutta on the one hand, and Bombay on the other. Besides grain, the soil produces good cotton, and there is a ready market for that fibre at Calcutta. At present, all grain and cotton from this district of Sumbulpore for Calcutta have to be conveyed a [illegible] week's journey to the river, and are then floated down to Cuttack or Chandbally, thus [illegible] a long and expensive journey. [illegible] a gentleman [illegible]

stationed at Sumbulpore, and who was compelled to visit Nagpore, came to Calcutta as the most convenient way of reaching Nagpore. He was thirteen days en route ere he reached the steamer at Cuttack. A railway through this district would lead to its being more generally cultivated, and in the course of time much more densely populated. Besides the benefit such a line will confer on the country through which it passes, we must not overlook the advantage Eastern India will obtain by being placed nearly a day nearer to Bombay. We presume this will be a trunk line, and on the broad gauge. If so, the distance to Bombay will be about 300 miles shorter by it than by the present line *via* Allahabad.

ANOTHER industry which might be developed in this country, is that of paper making. The quantity of paper used in the world in these days is enormous. The following is the annual production of paper of the leading nations:—

	Tons	lb per head of population
United States	207,000	10
United Kingdom ...	180,000	11
Germany ...	203,000	10
France	132,000	7
Austria	97,000	6
Italy	50,600	4
Russia ..	32,400	8
Spain ..	30,600	4

The increase in the use of paper is so steady that there is little fear of the trade being over-done, and the sources of supply for raw material are becoming more and more unequal to the demand made upon them. India has within herself sufficient raw material to supply the world with paper stock. Mr [illegible] interesting memorandum on this subject points out a vast number of [illegible] [illegible] suitable for paper making, but we need only [illegible] one, viz., the bamboo. Mr. Thomas Routledge, of Sunderland, England, who has given much of his time, attention, and skill to this subject, has placed the question beyond the experimental stage. He has made large quantities of paper from bamboo and other fibres mixed, and also from bamboo alone, and has had several magazines at home printed on those papers. The result is all that could be desired, and Mr Routledge tells us that he has satisfactorily demonstrated the cheapness of the fibre for this purpose, although he imported his paper stock under very unfavourable circumstances as to cost. There can be no doubt that in the bamboo forests of India and Burmah we have a source of paper-stock to fall back upon which will prove inexhaustible. No cultivation is required, only a little care in forest conservation. The paper stock is made of the young shoots about a year old, and by cutting down a forest in divisions, an endless supply might be obtained. All that is wanted is a pulping mill alongside of every bamboo forest, or a river if possible, and where clean water is available. The fibre could then be extracted, bleached, dried and pressed for export, leaving in the meantime the mills of England to finish the article. By-and-by India could take up this part of the industry as well.

COLONEL A. HARCOURT sends the following note to a contemporary:—"I think the theory, that an abundant mango season is a sure sign of an unhealthy year, should be received with hesitation. It is better, in making such forecasts, to go by past experiences, and in so far as I can recollect, a good mango year in the Punjab has not been an unhealthy year. In 1873 the mango crop in Upper India was at any rate an average good one and throughout the Punjab the year was healthy. In 1874 (I was then at Hoshiarpur) there was an undoubtedly excellent crop of mangoes, and there was little sickness; while in 1875, the crop was defective (in Hoshiarpur) and cholera prevailed everywhere. Again in 1878 the mango crop was an extraordinarily good one, the trees between Umritsur and Pathankot being bowed down with fruit, and in the Punjab there was little sickness, while again in 1879 [illegible] and the year was one of the most unhealthy on [illegible] crop is good, and hitherto in the Punjab the general health has been decidedly satisfactory. As to the flowering of the bamboo, I have not made any observations, for the bamboo is not a common tree in the Punjab. But I think there is another indication of a coming healthy and unhealthy year, and that is, the presence or absence of hornets and wasps. I was in Kurnal (Punjab) in 1873, and wasps swarmed everywhere. In 1874 at Hoshiarpur (a healthy year) the hornets and wasps were such a p[illegible] that it was im[illegible] to use the verandah at all; whereas in 1875 (an unhealthy year) hardly a wasp or a hornet was to be seen. I do not remember that in 1878 (a healthy year) wasps and hornets were troublesome, but in 1879 (a year of great mortality) there was a very few of these insects. This year in the place from which I write wasps are in great abundance everywhere. There are very few hornets, and the health of the district is excellent. The conclusions I myself have drawn are, that when there is a healthy year in the Punjab the mango crop has been above the [illegible] and wasps have abounded, while in unhealthy years the mango crop has been defective, and wasps have been remarkable by their absence. It may be that Nature has given us guides as to what may [illegible] healthy seasons, and forewarned we might [illegible] ourselves, for it is quite notorious that [illegible] with comparative immunity in a healthy year is [illegible] when disease is hanging about.

THE China opium question is a constantly recurring one. On the one hand we hear of Imperial mandates forbidding the cultivation of the poppy. These reports come from Chinese official sources. From Consular reports, and from the observations of the few travellers who are permitted to visit the Celestial Land, we hear on the other hand that cultivation is going on apace, and that while it is forbidden by Imperial edicts, it is [illegible] encouraged by the local governors, for the sake of the revenue it brings into the treasury and the [illegible] it puts in the way of those in [illegible]. The latest utterance on the subject is from Acting Consul W. D. Spence, writing from Ichang, who states:—

"O[illegible] cultivation in the West is free and its product is [illegible] of revenue to the exchequer, of pelf to [illegible]. Everybody [illegible] and everybody [illegible]. In these provinces there is no [illegible] and poor, lettered and unlettered, governing and [illegible]. The amount produced is rapidly increasing, [illegible], and from it are [illegible] in contraband channels at present. No Indian opium is consumed anywhere. It is hardly the province of a Consul [illegible] to draw morals from the facts which come to his knowledge, but I think it only right to say that so long as China [illegible], to say as many do, that 'England forces Indian opium upon her, and compels her people to [illegible] themselves' is perilously like nonsense. The [illegible] people who [illegible] a sense of duty which must command respect [illegible] throughout England, in season and out of season, are preaching what the actual state of things [illegible] pure delusions. In judging of the present attitude of this country towards opium production within its own borders, and in drawing reasonable conclusions therefrom, men who [illegible] prejudice and who are guided by intelligent discretion, not by blind zeal, should give more weight to the [illegible] of China than to their words."

We take this to be pretty near the truth. The real aim of the Chinese [illegible] is to get rid of the competition of the Indian drug, that they may be able to increase the excise duty on the home-grown article, and in time they will no doubt carry their point.

SIR J. R. LONGDEN, Governor of Ceylon, in his budget for 1881-82, referred particularly to the rapid strides which had been made by Colombo. Its breakwater was specially spoken of as a great work, and one which could not fail to improve the business of the port. The increase in railways, too, was noticed, although we scarcely think [illegible] went beyond the region of the common-place when he pointed out the benefits which were sure to follow the [illegible] of those useful works, and in the next breath declined to pledge himself to any further extension in the meantime. Colombo

proposes to have a water-supply; the iron piping has been received from England, and the municipal council now only wait a decision as to the reservoir, the site of which has not yet been decided on. The population of the island has increased at the rate of 1½ per cent. per annum during the last decade. The Governor takes up the subject of coffee-leaf disease, a vital subject to Ceylon planters ... mentions with commendatory remarks the experiments made thereon ... Mr. Ward. Mr. Ward's report, he says, "exhausts the subject, as far as it can be carried out in Ceylon," and "although Mr. Ward has not been able to suggest any mode of treating the disease which shall absolutely eradicate it he has at least given to the world in the life history of the Hemileia the true data upon which a mode of dealing with the disease may hereafter be founded, and in the meanwhile such remedial measures may be adopted as may enable the coffee to withstand the strain of the disease." We fail to see the slightest reference to Mr Schrottky's cure, either in this speech or in the Ceylon journals of recent date. The export of cinchona bark increased from 15 000lbs in 1870 to 1,161,989lbs in 1881. Tobacco, India-rubber, and other valuable products are also being grown in increasing quantities, and Ceylon will shortly cease to depend, as it formerly did, almost exclusively on its coffee industry.

The report recently issued by the Secretary of State for India shows that, during 1879-80, the accounts showed the receipt of interest at the rate of eight per cent on the seventeen and a-half millions sterling invested on irrigation in this country. In Madras, the receipts were as high as twenty-eight per cent, in the North West Provinces five per cent.; in the Punjab four per cent, while in Bengal the interest was only one half per cent, and in Bombay there was a loss. We believe that the large returns for Madras are accounted for by the fact that irrigation there, on certain lands, is compulsory. The lands are assessed as "wet," and a proportion of the revenue set down to the irrigation account, whether the ryot wants water or not. In Bengal, on the other hand, the system is supposed to be voluntary, the cultivator taking water or not as he pleases. It is obviously possible to do a thriving business with roaring returns on the Madras plan. If the seller is allowed to fix his own price, and to compel every one within a certain area to purchase whether he wishes to do so or not, he can hardly become a bankrupt. There is more than one store keeper in Calcutta who would undertake to make, not twenty-eight, but two hundred and eighty per cent. if allowed to sell beer, in the way that the Madras Government sells water. Permit him to fix the price that seems to him fair, and to make us all drink, even the teetotallers or—for he would not be too harsh—to pay without drinking the beer, and he would do well in his trade. We would see him for some years driving in state every evening, after which he would retire, to boast at home of his great business aptitude, which had enabled him to gather a large fortune in a short time. His self complacency would be as well founded as that of the Madras Government in the Irrigation Department.

Reuter has told us that the "cotton corner" has been successful, and that the manufacturers have been unable to extricate themselves from the net which had been woven around them. At a meeting of Lancashire spinners held at Manchester on the 16th September, an attempt was made to meet the machinations of the "corner" by closing the mills for a part of each week, and thus reducing the demand for the raw material. The cause of this failure is principally the existence of contracts as to time, which makes it imperative that the spindles should be *worked full time.* Even had this difficulty been got over, the victory would have been purchased at the cost of much suffering to the work people, who would thus suddenly have found their earnings reduced. The cotton spinners must find a more effectual mode of fighting the cotton ring. It appears that a considerable deal of annoyance was felt at the meeting because of the fact that many of the brokers, hitherto considered neutral, had joined the ring, and it was considered, and correctly too, that in thus acting they had forfeited the confidence of the purchasers. The only effective way of meeting this class of trading, or rather speculating, is for the consumers to become their own buyers. This must be done by co-operation. The spinners might appoint a good buyer, who should be in their interest and in their employ, and whose duty and interest should be to purchase as cheaply as possible. It would be advisable that this agent should purchase at New Orleans, and by purchasing for a number of spinners he could consign in shiploads, and thus secure the most favourable terms as to freight. The middleman or broker would thus entirely be got rid of, and the expenses attending this purchasing agent should be met by a small charge per bale, a charge which would practically be almost *nil.*

The Advance Report of the Ontario Experimental Farm for 1881 gives details of some experiments in feeding grade shearling wethers of the various breeds, embracing Cotswolds, Leicesters, Oxford Downs, and Southdowns. The lambs were got by pure-bred sires of the above-mentioned breeds, and out of common mixed-bred Canada ewes. They were dropped about the middle of March, and weaned July 1st. The exact date when the weights and measurements were made is not given, but it is not especially material, as these were all taken at one time, and simply for the purpose of comparing the various breeds with each other. The measurements were as follows:—

	Heart Girth, ft. in.	Flank Girth, ft. in.	Length. ft. in.
Cotswolds ...	4 3	4 0½	4 2
Leicesters ...	4 1	4 1	4 0
Oxford Downs ...	4 0½	3 11	4 0
Southdowns ...	3 11½	3 11½	3 10

The Cotswolds averaged 199 lbs; Leicesters, 198; Oxford Downs, 177, and the Southdowns, 157.

* * * * * * *

Farming in New Zealand, according to statistics lately published, seems to promise a fair opening for moderate capitalists who are not above work. A 100 acre farm of well watered land within a moderate distance of a railway station, and with the necessary buildings on it, will require a working capital of £471. The annual working expenses are estimated at £270 13s, and the returns £713 10s leaving a profit for the year of £492 17. Of course so satisfactory a result, with so small a capital, will not allow a margin for the losses consequent on a want of experience.

Not long ago we called the attention of our readers to the fact that the German Government had requested the Italian Government to interfere to prevent the wholesale massacre of song birds which takes place in Sicily, specially at the time of their annual migration. It appears from the accounts given in the German papers that the French are no less sinners in this way than the Italians. It is well known that the birds of passage gather in great masses on the coast of the Mediterranean just previous to taking their flight into southern climes, or immediately after their homeward flight. The most common means adopted is to construct an erection called *le poste* which is a single chamber of brick work, roofless, about 12ft square, in one wall of which apertures are provided for several guns. At a distance of a few yards are planted a dozen or so of pine trees, to the upper branches of which are fixed dry boughs and artificial perches, and to these are suspended cages containing decoy birds. Most of these birds have had their eyes barbarously gouged out as they have been kept in dark rooms to train them to sing, and the idea is that they would, if exposed to the light, become wild and restless, and lose their song. In this way thousands and thousands of birds of every kind are massacred, and the markets of Europe supplied with these delicacies. But the laws of nature cannot be violated with impunity, and it is instructive to find that the farmers in the south of France are loudly complaining of the increasing plagues of insects, worms, and every kind of vermin which are ruining their crops. In one place it has been found necessary to pass the most stringent laws for the protection of swallows, as the mosquitoes had multiplied to such an extent owing to their destruction.

Our Railway contemporary says:—

"Freight is now being carried from Chicago to Liverpool, *via* New York, for 4s ... and *via* Montreal for five ... per

hundred pounds; the most preposterously low rates ever known. The oppressed farmer of the West would promptly refuse to haul a load of wheat 30 miles at the rate for which railway, a canal, and steamship lines are carrying it half way across the continent, and entirely across the Atlantic ocean, a distance of over 4,000 miles. Would legislation, even of the most communistic stamp, ever compel a reduction to such rates as the railways are now voluntarily affording the public?"

Railways confer such incalculable benefits on a country, that our wealthy zemindars should contribute largely to their construction in their own neighbourhoods, from other considerations than a direct return in the shape of dividends. The price of food-grains would be cheapened, and the general condition of the people ameliorated. This would in time tell on the value of their property, and in this way, apart altogether from dividends, they would obtain good interest for their money. The charge of five annas per cental for carrying grain a distance of over four thousand miles, a considerable portion of which is by rail and canal, is equal to fifteen shillings per ton, or for the quarter of wheat, three shillings and fourpence. From Delhi to Calcutta the charge is eight shillings per quarter, and it is thirteen shillings per quarter from Calcutta to Liverpool. It cannot be too often said, that, until both of these rates are materially lowered, India cannot hope to do much towards supplying the people of the United Kingdom with wheat.

MR. A. B. HEWLETT, H.M's Consul at Canton, in a communication to the Indian Government, dated 22nd June 1881, says:—

The opium crop gathered this year is reported to have been generally above the average, and in some places, such as Honam and Kuldja, appears from the accounts of travellers to have been unusually abundant. The consumption of native opium is undoubtedly extending, especially among the lower classes, who cannot afford to indulge in the more expensive Indian article. The bulk of the native drug brought to Canton comes from Yunnan by sea by way of Pakhoi. Szechuan and Kueichow opium also reaches the Canton market, coming down the north and west rivers. In former years, and as late as 1874, Szechuan opium was brought here by the coasting steamers arriving from Shanghai. But the difficulty of transport down the Yangtsze and the rapacity of the officials at the numerous *likin* stations on that river, made the traffic so burdensome that it was discontinued for some time. Of late, however, an amicable arrangement was arrived at between the governments of the provinces where the opium was grown and those of the provinces through which it was to pass, that there should be a single and uniform charge made at the barriers, and that of a trifling amount compared with the former exactions. As to the Szechuan opium which comes overland, I am informed that it is brought the whole distance to Canton, and here sold publicly without paying any customs duty, or in fact any kind of governmental charge other than the *likin*, which is said to be comparatively light.

This is the way the Chinese Government refuses to draw a revenue from the "misery of the people," as we were told the other day by the Chinese gentleman who visited our Viceroy.

A RECENT return issued to Parliament gives some interesting details as to the land under cultivation in Ireland during the current year, as compared with 1880. Notwithstanding the disturbed state of that unfortunate land, the acreage under cultivation has risen from 5,081,084 to 5,191,361. This increase was evenly distributed over the country, as the following statement will show:—

	Acres.	%
Leinster	36,104	2·57
Munster	27,304	2·20
Ulster	35,210	2·02
Connaught	11,659	1·68
Total ...	1,10,277	2·17

The whole soil of Ireland is thus accounted for —

Cultivated	5,191,361	acres.
Under grass	10,091,688	"
Woods	338,858	"
Bog, marsh, and mountain ...	4,694,953	"
Total ...	20,316,860	acres.

THE anti-opium meeting at the Mansion House, addressed by the Lord Mayor and other celebrities, shows that the movement is not losing, but probably gathering strength. The only way to take the wind out of its sails would be for the Government of India to hasten to give up its monopoly, and let the industry and trade, under strict fiscal laws, pass int private hands.

THE *Rangoon Gazette* has an article on the growth of cotton in Burmah. It seems a good deal of damage has been done to the trade by the monopolies of the Burmese King. Of the cotton grown on both sides of the frontier, amounting to 7,000,000 lbs., about one-tenth is grown on the British side, and the *Gazette* sees no reason why the proportion should not be greatly increased. "There is any amount of unoccupied land in British territory similar to that in the neighbourhood of Meingyan where cotton is grown most extensively," and a paternal Government might do something to encourage the cultivation.

At present, cotton is considered not worth attention, and agriculturists take no pains with it. In most cases it is only sown as an auxiliary amongst other crops, or allowed to grow on sufferance as a weed which it is too much trouble to root out. In British Burmah there is scarcely an instance in which it is attended to for its own sake. A man who has a plantain garden scatters in it a few handfuls of cotton seed and takes no more care of it. If any crop results, so much the better—the fibre is gathered and sold; but no means whatever are taken to bring about a successful result. Now, this is not as it should be, and Government might be less usefully employed than in endeavours to put things on a better footing. The poor figure cut by Burmese cotton in the European markets is justified by its inferior quality, for it suffers from all the most important defects which can be alleged against it,—shortness of staple, yellowness in colour, and heaviness of seed in proportion to fibre.

In view to improvement, the writer proposes that Egyptian and other seeds of fine quality should be imported at the proper season, and bonuses offered to those cultivators who produce the best results.

SOME years ago the Chinese made an attempt to master the cotton spinning and weaving industries, and failed through their desire to exclude the European barbarian. They have now found out their error and propose to make another attempt. This time they will leave nothing undone to ensure success. If they succeed—and we see no reason why they should not, seeing the native of India has succeeded—it will be a heavy blow to the Manchester industry. Judging by the energy and enterprise displayed by the Chinese when they turn their attention to mercantile pursuits, we have reason to suspect that, the initial difficulties mastered, they will in time make cotton manufacture a powerful industry in China. Of recent years the trade in English and American cotton piece-goods has received a shock from the grossly immoral practice of over-sizing, sizing in fact not for the purpose of facilitating the process of weaving, but clearly for the purpose of cheating the ultimate consumer. The industry in India has fully established itself, and not only are all the mills kept at work constantly, but an ever-increasing demand has sprung up for articles of local manufacture. We even learn that some of the more enterprising Bombay manufacturers are considering the propriety of commencing an export trade to Africa. This is meeting Lancashire on her own ground in earnest, and if only the Chinese succeed as well, the manufacturers of Lancashire and Glasgow will have to look out for new markets, which may be found in regenerated Northern Africa.

A CORRESPONDENT writes to the Lahore paper:—In your issue of the 7th ultimo, appears a paragraph anent experiments made in England by Mr. John Tindall on the properties of sulphuric acid for hastening the germination of seeds. The properties of vitriol, as an agent for imparting vitality to wheat seed, and also as a preservative against the charcoal-like appearance of the ears of the corn, are well known to some of the agriculturists of the South of France. The latter say that wheat seed, scalded with vitriolated water, produces a healthy crop, and some of the seed, which sometimes,

would indubitably rot, if it was sown dry, has its powers of germination restored by the action of vitriol. I have no doubt that if tea or any other seed were treated similarly, a good percentage would be saved every year to the planter or to the cultivators.

I saw the scalding process some 25 years ago, and if my remembrance does not deceive me, the operation is as follows:—First of all put in a basket the quantity of wheat you wish to sow the next day. Raise to boiling point enough water to scald your seed. Remove the vessel from the fire and pour in the boiling water the vitriol stones; stir the water with a stick, froth or scum will be produced, I believe, and the water will rise in the vessel; do not be afraid; no explosion will take place.

When the vitriol stones are dissolved, which ought to be done in a few seconds, pour the water on the wheat in the basket. As the water is poured on the wheat, free escape must be allowed.

I could not prescribe the proportion of vitriol stones, but I think half pound of stones to a maund of wheat should be sufficient.

As the process is simple and cheap, native cultivators ought to be induced to try it.

We observe with satisfaction that the Punjab Government has decided on leasing out the water power of the canals in the province. The amount of power available is great, and is at present not utilised. On the Bari Doab Canal there are 26 sites, at which water power is available to the extent of 200 horse-power, and the new railway about to be constructed between Umritsur and Pathankote will pass within a few miles of all these sites. On the Western Jumna Canal, 4 sites of 200 horse-power are available, and 8 with an average of 150 horse-power. This then represents a total of 7,200 horse-power, which it were folly not to use. It seems to us that the power available is much more than this, as the standard for one horse-power has been fixed by the Public Works Department at 15 cubic feet falling one foot per second, whereas the acknowledged standard is fixed at 8·8 cubit feet falling one foot per second. This latter being admitted, the horse-power will show a total of about 12,000. The rates fixed upon are from Rs. 60 to Rs. 150 per horse-power per annum, commencing at the fourth year, the first three years to be free. These are liberal terms, and when the public have experienced the cheapness and convenience of this power, they will not grudge the increasing rates, which at their highest are very low. This example might with advantage be followed on other canals, and as we pointed out on a previous occasion, all those canals fed by the sub-Himalayan streams have many falls at very convenient distance.

The cultivation going on in the low land at the Salt Lakes does not seem to make such progress as is to be desired. The principal crops grown are vegetables and fruit for the Calcutta market. This is a species of cultivation that pays well. In and around the large towns of England are extensive market gardens, from which three crops a year are sometimes raised, and the occupation is so profitable that the cultivators can afford to pay most exorbitant rents. Calcutta is tolerably well supplied with vegetables, but it seems impossible to obtain a perennial supply of certain kinds, and each sort comes in but once a year in its season. Now, in this climate, there is no reason why peas, lettuces, &c., should not be in season all the year round. During the rains, it is necessary to give the young vegetable shelter from the heavy rain and excessive heat. There are, again, other table supplies which ought to be very much cheaper than they are. We would particularise potatoes, which are now selling at two annas the seer, a price ridiculously high, and equal to one shilling and nine pence per stone of fourteen pounds. At home they are not above a fourth part of this price There is great scope for potato cultivation in our neighbourhood, and if only the engineers can keep out the water from the reclaimed plots, they ought to grow root crops in great luxuriance. These have hitherto been found not to succeed, principally on account of wild pigs and rats, but surely these can be got rid of.

Nobody knows precisely where the potato came from originally. It has been found, apparently indigenous, in many parts of the world. Mr. Darwin, for instance, found it wild in the Chonos Archipelago. Sir W. J. Hooker says that it is common at Valparaiso, where it grows abundantly in the sandy hills near the sea. In Peru, and other parts of South America, it appears to be at home, and it is a noteworthy fact that Mr. Darwin should have noted it both in the humid forests of the Chonos Archipelago and among the Central Chilian mountains, where sometimes rain does not fall for six months at a stretch. It was to the colonists whom Sir Walter Raleigh sent out in Elizabeth's reign that we are indebted for our potatoes. Herriot, who went out with these colonists, and who wrote an account of his travels, makes what may, perhaps, be regarded as the earliest mention of this vegetable. Under the heading of "Roots," he mentions what he calls the "Openawk." "These roots," he says, "are round, some as large as a walnut, others much larger. They grow on damp soils, many hanging together as if fixed on ropes. They are good food, either boiled or roasted." At the beginning of the seventeenth century this root was planted, as a curious exotic, in the gardens of the nobility; but it was long ere it came into general use. Many held them to be poisonous, and it would seem not altogether unreasonably so either. The potato is closely related to the deadly nightshade and the mandrake, and from its stems and leaves may be extracted a very powerful narcotic. In England prejudice against it was for a long time very strong, especially among the poor.

The following are the rates of consumption of various articles in Australia, showing the quantities used per head per annum, the calculation being the mean of 1878-80—

Tea	8·05 lbs.
Coffee, Chocolate and Cocoa	1·09 „
Sugar	82·2 „
Rice	15·61 „
Dried Fruit	7·10 „
Spirits	1·43 gall.
Beer (imported only)	15·0 „

Compared with the consumption of the same articles in the United Kingdom, the difference is striking. These are—

Tea	4·66 lbs.
Coffee (alone)	0·97 „
Sugar	48·56 „
Rice	7·05 „

Unless Australia turns its attention to growing tea, this consumption opens up a fair future for trade with India. We do not think Australia will ever do much in tea growing, as the climate is not suitable, except perhaps towards the north, and even there the rainfall is deficient. This opinion receives weight from the recent success of the tea syndicate in introducing tea into Australia, and it is to be hoped that the efforts recently made will be followed up by a judicious nursing of the new trade.

The *Times of India*, which first drew attention to the ring among the owners of various steam lines running between Bombay and England, now tells us that the line of steamers chartered by the leading native piece-goods merchants of Bombay has commenced running. The first steamer left Liverpool on 10th instant, and subsequent steamers were to start from Glasgow, taking their dead weight there and coming round to Liverpool for their light freight. Thirty-six of the leading native merchants form the committee, very stringent regulations have been agreed to, and it is confidently expected that the scheme will prove a success. The market value of vendible commodities can never be permanently enhanced by artificial combinations. We are not aware of any combination among ship-owners in Calcutta, and yet freights now stand abnormally high. For instance we hear of £4-10 being paid per ton for tea to London. As a ton measurement of tea only contains about 900lbs., it follows that this freight is equal to nearly 1¼*d.* per lb. Taking the average value of tea in Calcutta at 15*d.*, this is a charge of 8½ per cent. on the value of the article, a charge much too high. Freights for tea per steamers from China average £3 10-0, and it must be evident that India is handicapped in the trade.

"It appears that a draft of a treaty was lately drawn up between the Chinese Government and Sir Thomas Wade, accord-

ing to which China agreed to open three more ports to foreign commerce, provided she were allowed to levy any duties she pleased on imported opium. The treaty was sent to England for approval, and the Chinese Government, in the belief that there would be no difficulty in the matter, opened the ports in question at once. The English Government, it is said, refuses to enter into such an arrangement; and the Chinese Government will therefore very probably close the ports again."

England naturally objects to the extinction of her opium revenue, and does not see why China should assume that she will agree to whatever terms she proposes. It is true that the extinction of the Indian opium trade is not explicitly arranged for in so many words, but the moment China is allowed to levy any duties she pleases on imported opium, the trade in the Indian drug will be ruined, because a prohibitory tax would immediately be imposed. This paragraph shows the true reason for Chinese objections to the Indian opium trade. So long as it is carried on as at present, China cannot levy any duty she pleases.

THE following is the produce per acre in Australia of various crops:—

AVERAGE PRODUCE PER ACRE

Year ended March 31.		Wheat.	Oats.	Potatoes.	Hay.
		Bushels.	Bushels.	Tons.	Tons.
1871	...	10·1	15·0	3·3	1·1
1872	...	13·5	18·8	3·2	1·4
1873	...	16·5	19·6	3·5	1·3
1874	...	13·6	15·7	2·9	1·3
1875	...	14·6	18·5	3·5	1·3
1876	...	15·5	21·9	3·4	1·3
1877	...	13·2	19·9	3·3	1·2
1878	...	12·4	19·4	3·1	1·2
1879	...	8·8	17·6	2·7	1·2
1880	...	13·3	24·0	4·0	1·5
1881	...	9·9	17·6	2·7	1·2

VEGETABLE WAX is obtained from the carnauba palm (*Corypha cerifera*). The lumps, as imported from Brazil, are about 3 lbs. or 4 lbs. each and bear the shape of the pan in which they have been melted; it is of light sulphur colour, with a lustre between that of wax and resin, and rather brittle. There were imported into Liverpool, in 1878, 80 tons; in 1879, 13 tons; in 1880, 40 tons; and the value has ranged between 35s. and 85s. per cwt.

It is shown, in a recent report of Her Majesty's Consul at Pernambuco, that the export of this wax during 1875-76 amounted to 18,668 kilos, valued at £758; in 1876-77, to 171,980 kilos., valued at £6,957; in 1877-78 it fell to 89,182 kilos., of the value of £3,168; and in 1878-79 to 1,542 kilos., valued at only £61. By far the largest portion of the wax finds its way to this country. It is shown that the decrease during the last year was due to the famine and drought which so severely crippled all industry in the province. It is not a little remarkable that, at a time when roasted date stones are proposed as a substitute for coffee, we should also learn that the stones or seeds of the Carnauba palm, when roasted, are used in Pernambuco as coffee.

IN the vicinity of Preston an experiment has been in the course of trial which we should like to see instituted elsewhere. Some time back the agent of a neighbouring estate divided a few acres of land into small holdings of five perches each. These were offered at reasonable but fairly remunerative terms to the Preston operatives, it being optional with tenants to rent one or more plots. Some forty at once came into occupation but a great many more applied, showing how thoroughly the experiment suited local requirements. Market-gardening on a small scale seems to have been the chief method of cultivation adopted by the operatives, and in this they have already achieved a considerable measure of success. The other day a competition took place among them for trifling prizes presented by the owners of the land, and the degree of skilled husbandry shown on the plots is said to have been quite surprising. Encouraged by this success, those who started the enterprise are about to parcel out several more acres in the same way, and in time, therefore, quite a little colony of operative gardeners may spring up in the neighbourhood of Preston, with the very best results, no doubt, to the health and morality of the amateur gardeners.

THE cultivation of new products such as Liberian Coffee, Tea, Cacoa, and India-rubber, has been largely extended and has been so successful that the enterprise has attracted the attention of even the villagers, to whom every encouragement in such cultivation is being given. There are still large extents of Crown land available for the cultivation of new products in the Western Province, and there is no doubt that, when better means of transport are secured to the Districts selected, these lands will be sold greatly to the advantage of Government as well as of the purchasers. In the development of these new resources new roads are especially required. In the Kalutara, Kegalla, and Ratnapura Districts there is already a large and steadily increasing area under cultivation of some new products, and the roads for which the planters have applied, if they can be openedin an in expensive manner, will, I consider, be productive to both planters and the Government. A through reconsideration of the Road Ordinance of 1861, and a more liberal adherence to its provisions in favour of minor roads, is however necessary before much progress can be made in the matter of district thoroughfares.

THE acreage now under sugar cultivation in all India may be estimated (moderately) at no less than 3,750,000 acres, inclusive of the production of the Native Feudatory states. The approximate extent of cultivation in the several presidencies and provinces is ascertained to be as follows:—

Bengal	...	...	1,400,000
Native Feudatory States	...	...	750,000
North-Western Provinces	...	...	703,163
Punjab	...	...	391,630
Oudh	...	...	203,538
Central Provinces	...	...	107,805
Assam (excluding hills)	...	...	85,738
Bombay	...	...	49,849
Madras	...	...	33,000
Mysore	...	...	14,737
Hyderabad, &c.	...	...	5,594
British Burmah	...	...	4,271
Scind	...	...	4,058

GOOD rice is sold at Madras at eight measures per rupee, while here in Bangalore the commodity is retailed at 12 seers for the same sum. Comparing these figures, it is but natural to assume that grain is cheaper here than in the benighted city; but when it is borne in mind that two Mysore seers are equal to one Madras measure, it will be seen that this is far from being a correct impression, as the equivalent of 12 seers is 6 Madras measures, so that in reality rice at Madras is cheaper by two measures or 4 seers as compared with the seer-rate at which the commodity is retailed in Bangalore. According to another calculation, a Madras measure is said to be equivalent to 1¾ seers (Mysore computation); but dealers in rice aver that this is a miscalculation, for from practical tests conducted by themselves they have found that the proper equivalent of a Madras measure is fully two seers. Among the natives in the Province, raggi is computed by rupee weight, a seer weighing eighty rupees.

FROM a report relating to our colonial possessions, and dealing specially with Gambia, we learn that the trade in cola nuts, *Sterculia acuminata*, is an attractive feature in the commerce of the Gambia. The cola nut is the product of the Sierra Leone district, and the trade in it, both at Sierra Leone and the Gambia, is almost entirely in the hands of women, to a large number of whom it affords the means of livelihood, and in many instances the acquisition of comparative wealth. The nut is largely consumed by the natives of the Gambia. It is of bitter taste, and produces no exhilarating effect, but it is said to possess the power of satisfying for a considerable time the cravings of hunger. For this purpose, however, it is much less used than it is as a luxury. The trade in the article is rapidly increasing. In the year 1860, the import was about 150,000 lbs.; in 1870, 416,000 lbs.; and in 1879, about 743,000 lbs.

A THOROUGH test is about to be made in America of the theory that large areas of arid country in the centre of the Continent can be made valuable for agriculture by means of artesian wells. The propriation made by Congress has been placed in the hands of scientific commission, and the sites for the wells will soon be selected. If a steady flow of water can be obtained from such wells, it will not be long before millions of acres of desert land will be converted into fruitful fields. The soil of the vast arid belt lying on both sides of the Rocky Mountains is by no means absolutely sterile, as its appearances seems to indicate. All it needs is plenty of water to make it productive.

THE proposed railway from Burrakur on the E. I. Railway by way of Raepore to Nagpore will be of immense importance, not merely because it will give us a more direct route from Calcutta to Bombay, but because it will traverse one of the finest grain-producing tracts of India, where the earth's abundance has been wont to rot because there was no means of conveying it to market. It is said that the scheme has been taken up in a practical way at last, and it cannot too soon be carried out.

THE millet seed is excellent food for fowls in winter, and if much of it is used an ordinary flock of fowls will get their living upon the manure heap and around the mangers. Millet makes a very nutritious feed without the seed, and all kinds of stock eat it greedily. The straw is coarse and rank, however, and feeds much nicer after being run through a threshing machine. In regard to the amount that can be grown on an acre, land that will produce 30 bushels of wheat per acre will grow 4 tons of fodder and 10 or 12 bushels of seed.

MR. K. F. NORDMANN, Executive Engineer, has been deputed to "reconnoitre" the country for a line of railway from Raepore to Vizagapatam. It will be his task to ascertain which of the following routes is to be preferred—(1) that starting from Purvatipory and passing *viâ* Rayaghada through either Bundisor or Dadpore east of the Nawagarh hills to Raepore, or (2) that starting from Salur and passing through Nawagarh west of the above hills to Raepore.

THE sheep-breeding farm at Nirayama-cho, Isu province, is progressing fairly. This month five or six catties of wool have been obtained from each of two rams and eighteen ewes which the farm borrowed last year from the Agricultural Bureau. Its quality being good, it is quoted at forty sen per catty, which price should give a good profit to the projectors. They are said to intend to establish another farm of the same description.

WE understand that the Mysore Dewan has been pleased to create three new scholarships of Rs. 10 each for native youths who are willing to prosecute their studies in the Agricultural College at Madras. With this object in view, proceedings we hear have already been passed, and a young man by name Seenapah, of Honganahulli Malur Taluk, has been granted one of the scholarships, and has joined the College.

FROM careful estimates which have been made at the French vineyards, it appears that no extraordinarily large output of wine is expected for the present comet year. The total anticipated yield for the 75 departments where the grape is cultivated is 32,004,816 hectolitres. It remains to be seen whether the quality of this wine will justify the popular belief in the influence of comets upon the vintage.

THE Cosmos Fibre Company of Dusseldorf is said to have invented a machine which is capable of perfectly cleansing the bark of China grass (*Boehmeira nivea*) of all resinous and woody matter. The inventors intend applying for the reward of £5,000 recently offered by the Government of India for such a machine.

THE Chief Commissioner of British Burmah has offered a reward of Rs. 250 for the best translation into the Burmese language of a Handbook of Agriculture (other than rice cultivation) for Burmah, by Mr. Martini. Translations may be forwarded to the Chief Commissioner till the end of November next.

DR. GILBERT and Mr. LAWES, whose work, in connection with the development of scientific agriculture, is well known, have we see, received by the decree of Emperor of the Germany the gold medal of merit for agriculture.

OFFICIAL PAPERS.

SETTLEMENT OF THE BAIGAS.

From Major A. BLOOMFIELD, Deputy Commissioner, Balaghat, to the Commissioner, Nagpur Division,—(No. 1288, dated 10th May 1881).

I HAVE the honour to submit as follows, regarding the Baigas of this district, with a view to further action being taken towards putting them in a satisfactory manner on a fair way to earning an honest livelihood.

2. The recent census has enabled me to ascertain the exact number of the comparatively few who still remain in this district. The following table contains in a simple form the result of the enumeration :—

Caste.	Men.	Women.	Boys.	Girls.	Total.
Binjwars ...	180	156	157	178	671
Nahars or Nahrotias ...	284	291	298	266	1,139
Bharotias ...	147	172	164	113	596
Total ...	611	619	619	557	2,406

NOTE.—There are a few mistakes in the translation in the name of tribe.

There are thus, roughly speaking, about 600 families and 2,500 individuals.

Divisions.

3. They are divided into three Ghots or tribes, *viz.*—

(1) Binjwars,
(2) Nahrotias or Nahars, and
(3) Bharotias.

These are distinct tribes in every way; they neither intermarry nor intermix in any way, and are seldom, if ever, found living together in one village. The Binjwars appear to be slightly Hinduized, and observe sundry petty rules of castle, as if, apparently, they desire to distinguish themselves from the other two tribes, between whom and themselves there is, in physique, language, &c., but little difference. They will not eat the flesh of the ox bison, nilgai, *e.g.*, rats, ant-eaters, squirrels, and many other things which are readily devoured and much appreciated by the other tribes.

Location.

NOTE—In the villages marked thus * they were not regular residents, but merely temporary sojourners for the time, making Tibur, &c.

4. The three tribes are not only found in separate villages, but in different parts of the district. The append ed list of villages in which the Baigas were living at the time of census shows that they inhabit—

(1) The Binjwars in the Paraswara and Man taluks, or, in other wards, the hills and ghats overlooking the upper reaches of the Wainganga river.

(2) The Nahrotias, the central hills of he Sanka taluq, the Dhansuwa pargana, the Saletekri and Bhanpur zemindaris, and further north towards the Mandla border. Before pressure was first brought to bear on them to stop their Bhewar, they were to be found nearly all collected in the central ranges of hills called—

Waijhari ... Dhansuwa Pargana.
Khandaparh ... }
Tipagarh ... } Sanka taluk.
Dukri ... }

the hills of the Hatta pargana, and the hills of the Bhanpur and Saletekri zamindaris. When the Bhewar was stopped in the Khalsa, they mostly went further east into the zamindaris, and since the dhya in the zamindaris has been stopped, they have been coming slowly back into the plain villages, near around the old haunts and hills of themselves and their forefathers. Within the last month or two, several families have emerged from the Bhanpur zamindari to settle in our most promising Baiga settlements of Karwahi* and Bhuddhutola.

*** These are in fact one mauza.**

(3) The Bharotias in the northern parts of the Bhanpur and Saletekri zamindaris, the hilly villages of Bhimlat, the Bhaisonghat range, and the hills of Raigarh Bichia. In these places and along the banks of the Bhanjar river, within the borders of the Mandla district. Since the stoppage of the Bhewar, most of them have gone over the border into Kanarda, where most of them would finally settle, were it not for the Begar that is exacted from them in lieu of land rent or axe tate.

Mode of living.

5. In the days of Bhewar cutting, the Baigas lived comfortably on the produce of their clearings, aided to some extent by the numerous roots, fruits, &c., of the jungles in which they lived. How they have managed to live since the Bhewar was stopped is really difficult to understand. The fairly good condition in which they now are shows

that they certainly have not starved. They certainly have been very hard pressed; some have borrowed grain from their neighbours and got considerably into debt, a state quite new to Baigas, and most have managed to keep body and soul together by selling minor forest produce in the bas aars, and subsisting chiefly on jungle roots, fruits and herbs, and fish from the hill streams. A few have managed to earn a little grain by assisting in trifling matters the cultivators of the neighbouring villages; and some malguzars have tried to give them work, but have found it difficult to discover anything they can put their hands to.

6. Before entering into the subject of the settlement of the Baigas, I ought perhaps to note a very marked difference in the character of the three tribes of Baigas—a difference which should be borne in mind in arranging for their settlement.

The Binjwars are the most civilised of the three tribes; several families living in the marginally noted villages of the Man valley have long been regularly settled as plough cultivators. Some of those in the villages marked† were so when I first came into the district in 1868.‡ They evidently take more readily to the plough, and have no great objection to live in the same villages as other cultivating castes.

† (1) Pondi.
(2) Gudma.
(3) Soukar.
No. 1 is the oldest settlement of the kind.

‡ Vide my letter of 1872 quoted further on.

The Nahrotias come next to the Binjwars. Up to 1870 the only one of them who had at all taken to plough was Ganu, the head of the Baiga village of Goara. About that time the pressure against Bhewar cutting had begun to tell. Mntira Pujari (also a Nahrotia) of Jaldidhar took to the plough in addition to a little Bhewar cutting, which at the time he frankly told he must cut, even if I cut his throat for it. Next, in 1871, § the Randarparhi Baigas, headed by the late Banjar Pujari, willingly volunteered to assist me in the tracking of the celebrated elephant, and on its being killed by Mr. Naylor and me, received the Government reward of Rs. 200. With this and some encouragement, and the good land of Karwahi, they were induced to come down from the rocks of Khandarparhi and take to settled plough cultivation, forming the nucleus of the most promising of our Baiga settlements. Since then the Nahrotias have been gradually taking to the plough.

§ *Vide* my letter No. 193, dated 26th March 1872.

The Bharotias are the wildest of all. I believe that not one of them has yet taken to the plough, and all who have come to me steadily maintain that they can never bring themselves to it.

7. My predecessor in his report No. 1596, dated 14th June 1880, showed what had been done for the Baigas up to that date. It amounted to this: 44 families were provided with bullocks at a cost of Rs. 1,254-8-0, and about Rs. 500 were expended on grain, implements, and so forth. Thus it seems that about Rs. 1,830 have been expended and 44 families have been provided with bullocks at an average cost of about Rs. 40 per family. It must not, however, be supposed that these families are permanently set up, for bullocks will die, crops fail, and wild men be improvident as well as unsuccessful in a calling entirely new to them.

Name of village.		Number of families provided with bullocks at one pair per family.	
Goara	...	8	Nahrotias.
Karwahi	...	24	Nahrotias.
Jaldidhar	...	6	Nahrotias.
Maldhar	...	4	Binjwars
Baiganagar	...	2	Nahrotias.
Total	...	44	

NOTE.—I do not believe this is quite correct; enquiries are being made.

8. During the current year, Rs. 787 have been expended in the purchase of 71 bullocks, which have been distributed as shown in the appended list B. About 12 pick-axes and 13 phaoras, old and much used, belonging to District Funds have been given, and about Rs. 200 to Rs. 850 will be expended in the purchase of seed grain to be distributed chiefly to those who have been recently supplied with bullocks. In this way the expenditure this year will amount to about Rs. 900, and 81*-families of Baigas will be so far provided. Thus on the whole there will have been a total expenditure of Rs. 2,730, providing for about 75 Baiga families at an average cost of about Rs. 40.†

* Exclusive of the 12 people supplied with 1 bullock each to replace deaths among those formerly given.

† This is leaving a margin for grain, &c.

9. The figures I have given above in paragraph 2 show that altogether there are about 600 Baiga families. Of these, about 75 have been provided with bullocks at Government expense, about 40 families have cattle of their own, and about 485 families remain to be supplied. This, at Rs. 40 per family, represents a cost of about Rs. 19,400.

Including those in the Man valley.

Binjwars; Nahrotias; Bharotias.

10. It may perhaps be urged that the fruits of the present system, which has now been under trial for nearly 10 years, are so small that it does not promise much success. This I venture to submit is not the fault of the system, but of the way in which it has been managed. I have not the slightest doubt that if the system be properly and steadily followed up, it will prove a complete success, and not many years will elapse before all the Baigas, even the Bharotias, will have become settled cultivators, quite happy and contented with their lot. Even now there are not wanting signs to show that the Bharotias are watching the progress made by the Nahrotias.

11. The only question is the expense that will have to be incurred to bring about this end, and this seems a proper place in which to insert a few words in favour of the Baigas, to show that they are in all respects worthy and deserving of all that may be expended on them.

12. The damage done by the Baigas has certainly been very great, for aided by the dhya cutting Gonds they have, with a very few exceptions, at periods more or less remote, closely shaven almost every hill in the district. In very rare places indeed is there a hill to be seen that has not a closely cropped appearance, with here and there a tuft of trees, or a single tree, showing what the jungle once was. Now arrivals in the district, and those who are not well acquainted with the Baigas, naturally feel indignant on seeing these devastations, and vow vengeance and reprisals in the way of burning crops, summary ejections, and so forth. But they entirely forget, if indeed they are not ignorant, of the rights which these Baigas might in all justice claim. For generations untold, probably from the time when the ancient Britons were yet clothed in their original garments of skins, the ancestors of these Baigas have lived, died, and been buried on the slopes of these hills and in the fastnesses of these jungles. They have supported themselves, their families, and their aged parents without the aid or interference of the State, or poor laws, or anything else, thereby setting a good example to the more civilized poor of the British Isles, and other countries. They have managed their own affairs without the aid of judge, jury, police or any Government officials; until the last few years they have escaped the grasp of inexperienced Extra-Assistants, and over-officious Police subordinates.

13. Surely then these Baigas might fairly claim absolute occupancy rights of the land they have held so long, or even be considered sub-proprietors of their holdings. They have not, however, in their wild ignorance, put forward any claim whatever. They have quietly bowed to whatever authority has been set up over them, and have never refused to carry out any orders that have been issued to them although they have frequently failed to act up to them. The stopping of the Bhewar cutting was the very taking of the bread from their mouths, yet although trusting to the negligence of native subordinates, they have in places continued to cut Bhewar, they have hardly so much as grumbled; they have given no trouble at all, but have quietly and cheerfully submitted to their fate and with no State aid worth mentioning, earned a hard though honest livelihood in their own quiet way. Had the Southals or Bhils, or the tribes on the Assam borders, been treated in this way, there would have been a very different story to tell; bloodshed and jungle fighting would have been the order of the day.

14. This being the case, I cannot doubt that you will agree with me that the Baigas are entitled to all credit and consideration at our hands. I do not advocate that they be allowed to return to their former wasteful mode of living, but (1) that by steady and continuous effort they be induced to take to regular cultivation, and (2) that they be assisted in every possible way to add to their earnings by any other means that may be most available.

15. I do not think it would be necessary to incur a very large expenditure in any one year, but I do not feel quite confident that a steady continuous pressure, coupled with unchanging kindness and an annual expenditure of about Rs. 2,000 in the direction already commenced, will have the desired effect. The Baigas should in every way be encouraged to bring all their troubles direct to the head of the district, and they will soon learn to be so confident in him, that they will ever be more ready to follow his advice.

16. It can hardly be expected that for some years to come the Baigas will be able to support themselves on the produce of their ploughs alone, and I would therefore assist them in aiding to their earnings—

(1) by working in the 2nd class reserved jungles, cutting timber and bamboos for floating down the rivers to the Madgi Station of the Nagpur and Chattisgarh line;

(2) by cutting and removing creepers which are now doing much damage

(3) by bringing minor forest produce to the local markets;

(4) by reserving to them the right to fish in the small streams above the ghats, of which the fisheries now yield no revenue to Government.

Working in forests.

16. (*a*). There seems to be some difficulty in inducing the Baigas to take to working in our forests. They are not perhaps generally steady workers, but in this case it is not perhaps the work they so much object to, as the forest subordinates under whom they have to work] Under European supervision, as has been proved during the sleeper operations* in the Banjar reserve, Baigas will work very well, but they have no

* In 1870-71.

confidence in forest subordinates. I am trying to get over the difficulty by giving them contract work, but cannot yet report any result.

Creeper cutting.

17. The creeper cutting work I propose to do by contract, allotting to each collection of Baigas a tract of forest in which to clear creepers from all good trees. It will be worse than useless to clear away all creepers, which now furnish to the surrounding agricultural communities a continual supply of valuable fibre.

Gathering minor forest produce.

18. I have endeavoured to encourage the Baigas not yet settled to the plough, to support themselves as much as possible, by the collection of minor forest produce. Tikur, Bychandi, and Chironji, and light bamboo work are the most important items in the Baiga's trade. I have prohibited the forest subordinates from levying any duty from the Baigas resorting to the markets with produce of this kind, for not only could they ill afford to pay the duty, but the trouble given to them in its collection prevented them to a considerable extent from resorting to the markets at all. The forest duty thus lost to Government, amounting generally to about 3 to 6 pies per head-load, is in the year something very trifling.

Fishing.

19. The Baigas of several villages have recently complained to me that the Dhimars of the surrounding villages have endeavoured to frighten them from fishing in the streams passing through the jungles in the neighbourhood. As these Dhimars have no rights whatever in the fisheries, which are trifling, and bring in no revenue to Government, I have given the Baigas written permission to fish, and prohibited the Dhimars from interfering with them.

(1) Karwahi
(2) Goara.
(3) Jaldidhar

20. It now remains to notice briefly the places I would select for the location of the Baigas, with a view to provide them with land suited for the plough. It may here be observed that my predecessor, Colonel Plowden, in his report on this subject, strongly condemned the places* where the Baiga settlements have already been commenced, and recommended in lieu the land of Chakarwa away in Bhimlat in the Upper Banjar Valley. But he was not well acquainted with the Baigas and their habits, and was ignorant of the circumstances which led to the selection of those places. The great desideratum is to get the Baigas to leave the hills and settle down somewhere in the cultivable valleys. Before they have tried their hands at the plough they are naturally and rightly doubtful as to their ability to support themselves by plough cultivation. They consequently cling tenaciously to the jungles and hills they have known from their childhood, and which they look to as their great reserve of all the necessaries of life. As this reserve it may be noted has been proved to be a never failing; for during the famine year of 1868-69 when the cultivators of the plains where so starving and wretched as to require State aid, the Baigas, notwithstanding the failure of their Bhewar crops, were in as good condition and as contented as ever. They will not therefore emigrate to any spot, however distant from their jungles, where the soil may happen to be good, but prefer inferior land nearer at hand. Hence it came about that in the beginning of 1872, in consultation with Runjur Pujari of Khandapur, I selected Karwahi, and Barwahi, these barren wastes, for their settlement. Karwahi, notwithstanding that a road has since been turned through it, is admitted by all to be by far the most promising of all the Baiga locations,† and now with its "tola" called Budhitola boasts of no less than 329 inhabitants, including those who at the census were temporarily absent at Kanhatola, but exclusive of the 10 households recently arrived. ‡ Barwahi has by some mistake been given on a ten years' lease to a neighbouring malguzar § instead of being reserved. Jaldidhar was selected by Mutira Pujari himself, and although not a very suitable place, has, as I expected when I agreed to it, answered its purpose in inducing several Baiga families to settle. Several who first settled in Jaldidhar have moved to Bhainswahi just outside the hills, and the Pujari himself is ready to follow so soon as land is found for him.

† To use an Americanism.

Men.	Women.	Children.		Total.
		Boys.	Girls.	
87	85	82	75	329

‡ These have agreed to settle in Sareka.
§ Of Pinkapar near Rupizar.

Goara was selected by Ganu Baiga himself, and is quite suitable, notwithstanding that the main road to Behir has since been turned through it. Baiganagar, under the Dukri hill, appears suitable; and Mallhar, away on the Western Ghats, will do for the Binjwars.

21. Having said so much about the sites already selected, I will mention a few places I would recommend to be reserved for the Baigas. The villages of Sareka and Jutta, situated within a mile of Karwahi, were leased for 10 years to the Patel of Bhandori, but as he has failed to come up to the terms of his agreement, the leases will not be renewed. In both these, there are large areas of good soil, well suited for the Baigas. Barwahi, which joins Karwahi to Jutta and Sareka, and is close to the jungles, should also if possible be reserved. I have arranged to locate a few families of Baigas at Kumdul, a small piece of good land lying to the south-west of the Tipagarh hill, and some of the Jaldidhar people have already come down to Bhainswahi on the opposite side. If these places shall prove insufficient for the Nahrotias, then the two Government villages of Gogatola and Parsatola, also close to Karwahi, can be made available for the purpose.

22. The Binjar Baigas can be provided for in any of the Government villages of the Man and Paraswara Taluks, or possibly they may be induced to follow the example of some of their caste fellows, and settle with other castes in permanently settled villages.

23. I observe that it has been urged that Baigas should be induced to locate themselves with ordinary cultivators in permanently-settled, villages, but I think I may safely say that great experience shows that for the present at any rate, this is not practicable except with the Binjwars, nor do I think it desirable. Alone the Baigas will learn to use the plough, and mixed with others they will learn no more except that which would be better left unlearnt.

24. The Bharotias will be found the most difficult to deal with. The stopping of their Bhewar has no doubt pressed them sorely, but I hope that now they see the only road left to them is to follow the example of the Nahrotias, they will gradually come down. They can easily be provided for in any of the waste villages of Bhimlat or Baigarh.

25 The late Tahsildar of Behir, Ramcharan Lal, rightly reported that there is great difficulty in collecting Baigas together in large communities. The Baigas when they disagree settle matters by separating. There is no particular advantage in making large collections of Baiga houses, and there will be no difficulty in settling them in small tolas scattered about the village lands. This has been done at Karwahi where there are 3 or 4 tolas, and is a common practice all over the district.

26. I will conclude by giving a brief sketch of an alternative, or it may be styled an auxiliary, scheme for settling the Baigas. I have long had it in contemplation, but have not been able to set it on foot.

27. The measures I have above proposed to be adopted by Government will doubtless go far towards establishing the Baigas as regular cultivators, but there are two points regarding which doubts arise in my mind, namely :—

(a) Will the Government agree to incur this expenditure, which for the present at any rate is in amount beyond accurate estimate ?

(b) Will the permanent improvement of the Baigas be thereby ensured ?

My auxiliary scheme will, I venture to think, go a great way towards stopping any possible gaps that may be left by the Government measure.

28 My proposal is to endeavour to induce the many charitable people and institutions in the British Isles, to send out a Mission to the Baigas ; for I believe that if a really good man such as many of the Missionaries are, could be permanently located amongst them, their permanent improvement would be ensured. and not only this, but that much good would result to the country for many miles round.

29. When last on furlough, I wrote a paper on the Baigas, and sent it round to several Missionary Societies. Most seemed to have their hands very full, working up to the extent of their incomes, and pleaded want of funds, but the Free Church Mission of Scotland said they would undertake the work, if I could guarantee them about £150 a year.

30. Now, I believe that the difficulty about funds can be easily overcome, for apart from any contributions that might be made from Imperial, Provincial and District funds, the money that could be raised from private individuals at home and in this country would suffice to meet all demands. Possibly also the Aborigines Protection Society would give some help. But before the public can be expected to take any interest in the matter, it will be necessary to lay the case before them in a popular manner. This I propose to effect by writing a short paper about the Baigas and circulating it in great numbers amongst all who will probably answer to the call. The only difficulty I have is in the printing, but if the Chief Commissioner, after approving of the draft pamphlet, would sanction this being done at his office press, I would during the ensuing rains re-write in an abbreviated and amended form the paper I drafted in England.

31. I have now only to express my regret that the statistics accompanying this report are not nearly so full as I should have wished, but not finding the materials ready, I preferred not to delay the report for them. I have taken measures to have fuller information ready for the next annual report.

No. 164, dated Simla, 28th September 1881.

From E. C. Buck, Esq., Offg. Secy. to the Govt. of India, Revenue and Agricultural Department,—To the Chief Commissioner of the Central Provinces.

I am directed to acknowledge receipt of your Officiating Secretary's letter No. 3150-176, dated 1st September 1881, submitting a report on the progress which has been made in inducing Baiga families of the Mandla and Balaghat Districts to settle down to regular cultivation by furnishing them with the means of husbandry.

2. In reply, I am directed to express the satisfaction of the Government of India with the results so far attained and with the active efforts which Major Bloomfield, Deputy Commissioner of Balaghat, has successfully made to reclaim these hill people.

3. I am further to inform you that, subject to an annual report of progress, the Governor-General in Council sanctions the yearly allotment of Rs. 2 500 from Provincial Revenues for the next four years, as requested in the 14th paragraph of your letter under acknowledgement.

E. C. BUCK,
Offg. Secy. to the Govt. of India.

LAND TENURES OF TRAVANCORE.

MEMORANDUM.

THE land tenures of Travancore may be chiefly divided into five classes, *viz*:—

1 Jenmom
2 Enam
3 Service
4 Pandara Ootty
5 Pandara Pattam

2. There are no records to show how the Jenmom right originated, but traditional accounts state that Parasurama reclaimed from the sea the country called Malayalam (hill and depth), colonized it with Brahmins from the Paundy country, built pagodas in various parts of the Principality, and granted at the same time in gift extensive tracts of land for their maintenance.

3. Jenmom lands are completely free from assessment, but this exemption ceases whenever the lands pass out of the hands of the original proprietor on any pecuniary tenure. In such circumstances they are liable to be assessed with Arilonoo or Ettilonoo, *i.e.*, one-sixth or one-eighth of the full tax on garden land and mooperah, *i.e.*, three-tenths of the average full tax on paddy land.

4. Classes of Enam lands are numerous, such as Adima, Anoobogom, Thiroovolom, Thiroovadayalom, etc.

5. The quit rent on this class of lands is generally about one rupee per acre, which is increased in proportion as the lands permanently change hands. The tenure under such circumstances is converted into Pandara Ootty.

6. Vrithy or service lands, a considerable portion of which has been enfranchised by the State, are still retained under the original tenure in consideration of the services exacted by the Government from their holders.

7. Pandara Ootty lands are those which are held under mortgage by the ryots from the Sircar, and *vice versa*.

8. The sale of Ootty lands is also accompanied by an augmentation of the original quit rent.

9. Pandara Pattam lands mean Sircar or Government lands. They form the largest portion of landed property, and include Jenmy lands which had been escheated to the State, private lands which, having fallen waste, have been relinquished by their proprietors, service and other lands which have been confiscated by the Sircar, lands which have been reclaimed from the Sircar wastes, and lands which have been purchased by the Sircar.

10. The ryots are secure in possession of such lands under the Royal Proclamation of 21st Edavom, 1040, so long as they pay the stipulated tax thereon. They are not, however, allowed to relinquish them unless they show satisfactory grounds for relinquishment. No remission of tax on account of drought or other adversities of the season is granted generally on such lands, unless the calamity is proved to be *universal* and *unusual*. In view to compensate the holders of such lands for contingent losses arising from deficiency or failure of crops in ordinary seasons a reduction of 20 and 30 per cent. in the Ayacut rates had been made, 20 on Pattom and 30 on Vrithy Pattom land. This reduction does not, however, extend to Pattom lands paying tax below one parah of paddy for every parah of seed land. For improvements made in Sircar Pattam and Ootty garden lands the Government allow in favour of improvers a deduction of one-fourth of the full assessment thereon.

11. By a proclamation passed by His Highness the Maharajah under date 2nd June 1865 / 21st Vycasy, 1040, all Pattom land holders have been made proprietors. The Sircar has given up all arbitrary power over these lands, reserving to itself only the right of regulating the assessment on them.

12. Whenever Nair families become extinct, all the property, movable and immovable, of the last surviving member, becomes escheated to the Sircar. Distant or collateral heirs may succeed to the property on payment of certain fees, equal to a share varying from one-fourth to one half of it. Adoption is also sanctioned by Government on payment of the usual Adyara fees.

13. The property thus escheated is generally sold by the Sircar by public auction, and the assessment on the landed property is then revised under existing rules.

14. Government waste lands are granted under the following rules:—

Whenever any application is received for any piece of waste land, order is sent to the local Tahsildar to make inquiries whether there are any objections to the grant of the same, and if none exist, to ascertain and report the exact extent of the waste land applied for, and the rate of assessment to which it is liable according to standing orders; *i.e.*, the highest rate of tax borne by the adjoining wet lands, and if no such lands exist, the tax determined by Vizours or assessors. If the report shews no objection, the matter is reported by the Dewan Peishkar to the Dewan, who, except in the case of Europeans, passes final orders thereon. If the applicant be a European, the case is then referred to the Palace and settled according to His Highness the Maharajah's commands.

15. If the waste applied for be found to be situate within the limits of Edapully or Vauchcapulay Edavaga, or if found to be a part of any cherikal belonging to any private Jenmy, the applicant is referred to the Edavaga chief or Jenmies.

16. Tax on garden land is 4 chuckroms for first class cocoanut tree, 3 chuckroms for second class, 2½ chuckroms for third class, and two chuckroms for fourth class; 4 chuckroms for jacktree, and one-eight chuckrom for areca nut tree. Tax on waste lands not planted with taxable trees is generally 4 annas per acre.

17. The rule is different as regards the grant of registered waste lands which had been once cultivated. They are disposed of generally by public auction, and the highest bidder secures them on Ayacut rates. They are sometimes granted for a certain period on lower terms if competition does not exist. Hill paddy cultivation is taxed at one-tenth of the gross produce for Government lands and one-twentieth for private Jenmy's lands.

18. The land revenue system is Ryotwary. The revenue is collected by the Sircar servants directly from the landholders.

19. There are some farms the rents of which the farmers pay directly to the Sircar according to the terms of their contract, the collection of the rents from the ryots being made by the farmers themselves. But this system of farming is much discouraged now-a-days.

20. Each ryot is responsible for the revenue so far as it bears on his individual holding. If he fails, his property real or personal, is sold for the satisfaction of the Government demand, and at times his person is also placed under restraint. So long as he has the means to pay, he must pay, whether or not he cultivates his quota of land.

21. In cases in which the ryot is unable to pay the tax, or in cases in which his lands on which the tax is due are washed away by rivers or otherwise permanently placed beyond the possibility of cultivation, the tax is then written off his name.

22. The assessment on the lands abandoned in consequence of the holders's inability to pay tax readjusts itself according to the productive capacity of the land, under the operation of the Durkast system.

23. There are large extents of Kundookrishy lands (crown lands) in the Districts of Ambalapulay, Chunganacherry, Cottayam, and Yettoomanoor. The revenue of these lands is collected wholly in kind by a number of Vicharipcars under the superintendence of a separate Tahsildar, and is appropriated for public purposes. These lands are treated differently and are governed by different principles.

24. Ordinarily no remission of tax is allowed for Government lands left waste. Whether the ryots cultivate the whole or a part of their respective holdings, or whether they cultivate them with paddy or sugarcane or any other production, they are required to pay the fixed tax, and the Sircar does not generally interfere in the way of ascertaining every year the extent and nature of the crop raised by each ryot on his individual holding.

25. The rate of assessment varies both on wet and dry lands. The assessment on Pattom lands ranges from one-eighth to ten parahs of paddy on a parah of seed land. The average assessment comes to something less than half a rupee per parah of land, or about four rupees per acre. Besides these, there are various extra cesses called Chathacooly, Mathapayara, Kottoocooly, Attoovaree, etc., amounting on an average to nearly four annas an acre.

26. Enam lands, such as Adima, Anoobhogom, Thiroovolom, Thiroovadayalom, etc., are subject to a moderate quit rent called Mooperah Vithara, Michavarom, Vithudal or Cadama. The average assessment on this description of lands amounts to generally not more than two annas per parah, *i.e.*, a little more than a rupee per acre exclusive of an extra cess called Choomattoopanom, generally about two annas upon each holding.

27. The land tax is settled in kind, but payed partly in kind and partly in money, according to the Pattayom granted in the Malabar year 949; garden tax is paid mostly in money, and in a few cases in cocoanuts, cadjans, oil, etc.

28. Upon what principle the settlement of the land revenue was originally founded is not quite clear at this distance of time. But it is obvious that the assessment does not appear to bear a just and equable proportion either to the gross or nett produce of the land. The principle seems to be different in different places, and this variation is perhaps due to the difference of systems which had formerly obtained in the several petty states which were absorbed into the present kingdom of Travancore.

29. In Shencottah Talook, Veedippoo, *i.e.*, the average collection of a series of years, has been made the basis of assessment, and in the Augusteswarom Talook the Ayakut account of the year 949 guides the collection of tax.

30. The commutation rate is low, it being only about half of the current market rate. This advantage is not, however, shared equally by

all ryots. In the greater part of the country the proportion of the grain to the money payments is not fixed at one uniform rate. It is genera'ly made dependent upon the extent of consumption of paddy in Devasoms and Ootooparahs in each Proverty. In some places the proportion is eighty per cent., while in others it is as low as ten.

81. The revenue is paid by several instalments. The garden tax by ten, commencing in (*Awany*) August, and terminating in, (*Tycausy*) June; and the land tax by eight, from (*Arpasy*) October, to (*Tycasy*) June, and in some places where there is Madapoo crop to (*Auny*) July.

82. Each talook is divided into from five to ten Proverties, and the division is made in reference to the extant and revenue of each talook. The Proverticar is held responsible for the collection of the land revenue of his Proverthy. This functionary has under him 3 or 4 accountants and 2 or 3 revenue peons. Besides this establishment he has at his disposal a large number of Mullacars and Vrithicars placed in charge of respective villages under him. The Mullacaren is considered as the head of the village over which he presides, and has generally 8 or 12 Virathicars in his Mullay. These Mullacars and Virthicars help the Proverthicars in the collection of the Government dues, in the supply of provisions to Devasoms and Ootapurahs, and in sundry other matters. They are remunerated by the produce of lands granted to them at low rent, and their office is hereditary, the eldest member of the family generally succeeding thereto on the payment of the usual Adyara.

83. The land revenue is paid by the ryots into the hands of the Proverthicars. A Kykanakoo (puttah) attested with the Sircar seal is given at the commencement of every official year to such of the ryots as require it, showing the number of lands and gardens registered in his name, and the rates of assessment payable thereon and other necessary particulars, and all his payments to the Sircar are either endorsed on the back of this document or acknowledged in separate receipts.

84. The Proverthicar sends all the money collected to the talook treasury generally once a month, retaining in his granary all the paddy collections to meet the current requirements of his Proverthy. He assists the Tahsildar in the conduct of various revenue matters and also in the detection and suppression of crimes He is also a Marahmut Vicharipooca, in his Proverty, and is responsible for the conservancy of village roads, canals, etc.

SELECTIONS.

BEE-CULTURE IN INDIA.

BEES' wax and honey form no very insignificant items in our trade returns. People in India care very little for bee-culture; they are content to know that particular districts of Southern India afford both these items of luxury and medicament; some few may try to be critical about Cuddapah honey, but about the honey-bee of India most of us are as ignorant as those simple rustic folk in England, who, though "bee-masters" themselves, yet are in blissful ignorance of the full value of their interesting charge, their instincts and habits. Among the insects of commerce which India possesses, there is a *haitus* left in respect of the bees which amounts almost to neglect of the gifts of Providence. Not many months ago a project was talked of for utilising the countless tons of bats' manure which the hill-caves of Cuddapah were said to contain; whether it is to come to any head, or is to remain in the category of things *in posse*, remains to be seen. In the meantime it is interesting to know that Indian bees are beginning to be recognised as very promising creators of wealth, and that a venture is about to be made for ultilising the Indian bee to the purpose, if not to the same extent, that it is in France and elsewhere. Possibly, with the peculiar views held by certain classes of Mussulmans of the sacredness of the bee, some little opposition to its being domesticated may ensue, but it is not likely to be long-lived. It is a very remarkable fact that customs and prejudices exist long after the age which give birth to them. The hill-men of Cuddapah go out after the honey and wax, which they exchange with the low country-folk with instruments of barbaric sound. We wonder if they have heard at any time of Virgil and the directions he gives,—when you see the swarm issue from the hive, watch them attentively and raise tinkling sounds and clash the cymbals of Cybele. Somehow, the prejudice is both an old and deeply-rooted one which ascribes to bees a love for discordant sounds. To return to our muttons: an adventurous gentleman, whom a recent number of the *Tropical Agriculturist* named, is, we learn, about to start bee-culture in India. People have ventured on silk worms, and recorded successful issues, and we see no reason for believing the bees of the country to be more intractable. Bee-culture may have some little difficulties at first to contend with; so has silk-worm rearing, and what patience and unremitting care has compassed in one instance, they may succeed also in compassing in another. Cuddapah honey bears a high commercial value; when pure, it has a bright light yellow hue: it is only after it gets into the hands of the bazaar man that it acquires the mawkish taste and dull color that it does when it is brought into the market. We venture to predict a promising future for bee-culture in districts whose conditions are favourable to the industry, and trust Narbonne may find a formidable rival in Cuddapah and other honey-yielding tracts. It is not likely that the little honey used in hospital practice is always from Europe; and we see in the determination of Government, to utilise as far as practicable local supplies, an earnest and a guarantee that local efforts will meet with all the support that their real merits entitle them to. To the present day the caves of Salsette and Elephanta are as much frequented by bees as were formerly the clefts of rocks in Palestine, and as now are the fissures and crannies of the Cuddapah hills; no one either in this presidency or at Bombay, or for that matter any part of Asia, has tried to domesticate the bee, and the credit will be all the greater when some one shall be found to dissipate the illusion that the honey-bee of India is an [illegible] creature.—*Madras Times*.

COFFEE AND TEA.

A RETURN has been submitted to the Madras Government, showing the number of coffee and tea estates in the different growing tracts in this presidency, the number of existing plantations, the yield of coffee and tea and the cost of cultivation. The progress which these industries have lately made and the large amount of capital invested in them have induced the Government, for the purposes of preparing the necessary statistics, to obtain these returns which however are quite what are wanted. The column showing the number of plantations is misleading. Is it to be inferred that there are so many coffee estates in the different districts or that the estates are divided into so many plantations? We find it stated that, in the Madura district, there are 2,779 coffee plantations containing a total acreage of 4,581, so that each plantation is not quite two acres in extent. It would have been better to give the number of estates and their extent. But to the returns. We find that coffee is now grown in eight of the twenty-one districts of the presidency. In Vizagapatam there are only six acres of land planted with coffee; in Madura 4,581 acres, of which 3,059 acres are filled with mature plants, in the Tinnevelly district 2,844 acres of land have been taken up for coffee, and 2,005 acres are fully planted out. The coffee industry in the district having turned out well of recent years, has induced many persons, to open up estates chiefly in the Tenkasi and Nanguneri taluqs. In the Coimbatore district very little progress has been made in opening up estates, for while about four thousand acres of land have been taken up for the purpose, about 816 acres contain mature plants. In the Nilgiri taluq 22,648 acres are fully planted out, 221 acres contain immature plants and 21,255 acres taken up for planting have not yet been planted out. The approximate yield of the coffee estates is returned at 10,128,799lbs. at the average of 447lbs. per acre, the cost of cultivation being Rs. 100 to 130 per acre. It is to be feared that the next returns will show a large decrease under this head owing to the fact that many plots of land have, since the past ten months or more, been made over for good mining purposes. In the Salem district the number of plantations is given at 323, the acreage planted with mature plants 3,932; with immature 1,662, and the acreage taken up but not planted 5,075; total land taken up for coffee 10,667 acres; approximate yield of coffee 983,000lbs. The cultivation of coffee on the Shevaroy Hills is being pushed on steadily by the owners of estates, but there is just now not that desire to launch out capital in the enterprise as was the case fifteen or twenty years ago. In many cases, the estates have brought their owners large returns and, as in all other matters, a great deal depends on personal supervision, and where this is properly exercised, success is secured. The present year has not been a very favourable one for coffee on the Shevaroys; the rains have been late, but notwithstanding some of the estate have given pretty fair returns. The Malabar district which includes the Wynaad, has a total of 31,061 acres under mature coffee, the land taken up for cultivation being returned at 62,128 acres and the yield given at 6,114,826lbs. In Cochin about 7,795 acres have been taken up for coffee, of which only 1,436 have been planted. In Travancore, the extent of land planted with mature and immature plants is 16,775 acres against 37,067 taken up. For the entire presidency, the figures are as follows: mature plants 78,822 acres; immature plants 13,463 acres; not planted out 83,925 acres; total land taken up for coffee 176,210 acres approximate yield of coffee 21,492,682lbs. The Travancore estates give an average of 175lbs. of coffee per acre of mature plants against 323lbs. in Cochin and 197lbs. in the Wynaad.—*Madras Standard*.

AN AGRICULTURAL DEPARTMENT FOR BOMBAY.

WE pointed out the other day, in connection with the contemplated local extension of the Department of Agriculture, how meagre and often inaccurate are some of the statistics supplied in the annual Administration Reports of this Presidency. In 1872 the Government of India, to ensure uniformity in statistical returns, enjoined on all local and provincial Administrations the adoption of new statistical tables as perform prescribed by them. These tables have accordingly been appended to the annual reports since 1872-73. Few readers of Administration Reports have the patience to go through these statistical returns; but any one who has the curiosity to examine them with a view to extract any valuable information therefrom, returns back from them disappointed. One of the most vital questions of the day, for instance—one in which the statesman in India, no less than the ordinary tradesman, is interested—relates to the food supply of the country. What is the total food supply of India? This question resolves itself into the question of the produce of food in each Presidency, and that, furthermore, into the question of the supplies of each district. Similar information is needed in respect of the Native States. Taking, however, for the present, British districts of our own Presidency, we doubt if any of our district collectors are able to tell us, within approximate limits, what is the quantity and value of the food produce of the districts under their charge, what is the consumption of the people, and what is the surplus stock left at the end of the year to meet a threatened scarcity, drought, or famine. It may not be the collectors' fault; but there is, nevertheless, the broad fact that on a vital question, on the right determination of which depends the wellfare or woe of millions of people, tolerably correct or reliable data cannot be had. Even the compiler of the *Bombay Gazetteer* has not been able to give the statistics of food supply in all except two or three districts. The fact is such statistics are not to be had. No wonder, then, that even the Famine Commission should be left to guess, or form a vague general idea of the stocks and surplus food produce of each of the large divisions of India. The Commission tells us that, from rough estimates made from data of which the best it can say is that "we hope to see them more accurately established," the increased production of the country has kept pace with the requirements of a growing population. Now, we need no Famine Commission to tell us this. We all know that in ordinary years, with a fairly favourable season, India is not only able to produce food sufficient for its own population, but to leave, over and above what is actually consumed, surplus stocks to meet any immediately threatened contingency. We know, moreover, that large tracts of land may yet be brought under profitable culture, and that with improved methods and extended irrigation, there is reason to believe that increased production may yet be secured. [illegible] is whether and how [illegible] fluential [illegible] in many parts of the country [illegible]

arable lands, to an extent which scarcely leaves good culturable land available for the supply of the future needs of an increasing population. Such fears admit of being easily allayed by a careful compilation of statistics And no time we think is more suitable for this than the present. The period after the famine may be made the starting point of more complete and accurate statistical inquiries, as was done in Great Britain some four-and-thirty years ago. Mr. Caird tells us that statistics in the United Kingdom began to be collected from the time of the potato famine of 1847 in Ireland. "Not for twenty years" says he, "were there any complete returns from Great Britain After long perseverance, I succeeded in obtaining a Resolution of the House of Commons in favour of the collection of agricultural statistics, which were in consequence carried out for the first time in 1867, the collection of the returns being made by the officers of the Inland Revenue, and their arrangement for publication by the Statistical Department of the Board of Trade ;" and fourteen years' repetition of the inquiries has supplied the officers of the Inland Revenue with such a fund of information as to admit of no question as to the substantial accuracy of their returns. It is not, therefore, too much to presume that an era of correct agricultural, vital, and economic statistics may dawn upon this country by the starting into life of the Agricultural Department.

We may here briefly indicate the directions in which steps may be taken to ensure more correct and complete returns, since it is hardly necessary to repeat that upon their completeness and accuracy will depend the public view of the prospects of every coming year in India—prospects in which the Government, no less than the mercantile and general public, are interested. As a first step, the present returns of rainfall in every district require to be more accurately framed. Old and ricketty rain-gauges now in use in some districts must be replaced by new and improved gauges, and arrangements must be made for a regular registration of the gauge indications by responsible persons, and not through the agency of office sepoys or pattiwallas as is often the case now. Government, indeed, supplies us with weekly season reports purporting to convey information to the public about rainfall, state of crops, prices of food grains, &c. We have no wish to condemn these reports, but the best thing we can say of them is that a great deal of paper and printing is wasted upon them. At all events the reports might be made to subserve the ends of statistical inquiry much better than they do at present. Any one who examines these weekly season reports a little closely will find, first, that the record of rainfall given in them has reference to the fall only at the head-quarters of the district, and secondly, that it gives the total fall of the week. But the rainfall at the head-quarters affords, we submit, a most inadequate measure of the rainfall of the entire district, which contains some eight or ten talukas or sub-divisions each covering an extensive tract of country. Again, it is not an unfrequent phenomenon of rainfall in this country that a sudder station may be blessed with a full average rainfall, while talukas of the district may be without a drop of rain, so that plants may wither, and crops may be destroyed there, though the sudder station may be all the same for such deficient fall in the talukas. Then, again, what is of much importance to the steady growth of crops and a bountiful harvest, is a *seasonable* rainfall, more than a sudden and excessive downpour. Half an inch of rain every day for a week, for instance, assists a healthy growth much better than a sudden downpour of four inches of rain in a single day. These phenomena the season reports do not, it may be seen, well record. The same remarks apply to cultivation returns, and to crops and prices. Nobody in the district, so far as we are aware, is responsible for correct returns as to cropped areas devoted to wheat, bajri, peas, orchard produce, drugs and narcotics, condiments, starches, oil-seeds, dyes, cotton, fibres, &c. We make bold to say that the figures given under these heads in the tables for agricultural statistics, according to the forms prescribed by the Government of India, are mere guesswork, put down according to the fancy of the village kulkarni. They cannot stand the test of a moment's examination, the fact being that there is no organized agency to look after the work, and nobody to check the figures. As to prices of food grains published every week, one is at a loss to make out whether they are retail or wholesale prices, and whether they are the prices ruling at the sudder station of the district against which they are marked, or the average of the taluka's prices. All these circumstances, trifling as they may at first sight appear, cause variations in prices Unless the varying causes are recorded, prices of grains in a district afford no better indication of its economic condition than the figures of rainfall. Another element in determining the question of the quantity and value of the food grains in a district is the average yield per acre of its staple products This is usually done by means of crop experiments conducted in a hap-hazard manner, which afford no scientific basis to work upon. In short, until the Statistical Department is organized as a special and distinct agency well trained to its work, there is little hope of problems such as those of food supply and home produce, of surplus stocks, prices, and economic conditions meeting with their proper solutions. If the proposals of the Famine Commission lead to the organization of a trained special agency such as we advocate, and which will supply the requirements of modern statistical science, the Commission will, we consider, be looked upon as having done no small service to India since no better way can be suggested of setting at rest many economic questions of the highest importance which at the present moment are matters of controversy in the absence of correct statistical data —*Bombay Gazette.*

INDIGO IN THE PUNJAB.

THOSE of us who have sufficient of the old Adam left to retain the primeval instinct of gardening, must often have undergone the humiliating experience of finding some self sown plant blossoming gaily in the border long before its carefully nurtured, theoretically-grown pot companions thought of a bud, Indeed, one of the most striking characteristics of India is its passive resistance to whip or spur. The very soil resents being hurried and worried ; it cannot run with new fangled experiments, deep ploughing, and artificial manures ; but if left to take its own course gives —proportionately to the labour spent—a very fair result. So, while the Department of Agriculture and Commerce make costly experiments of superphosphate of lime on *kunkur* soils—a curious experiment, by the way, seeing that the infertility of such land arises from a natural excess [illegible] while they report on the growth of guinea-grass and compare cotton staples, while European companies are started to give an impetus to the [illegible], and Government talks [illegible] in its revenue reports about prickly chomfier and *eucalyptus* trees ; little and self-sown industries, such as the manufacture of Indigo in the Multan and Mozaffargarh districts, spring up here and there, strong and vigorous. Indigo has, we believe, been grown there in small quantities since time immemorial, but the increase of cultivation since the extension of canals, especially in the last named districts, is simply marvellous. Nor do we wonder at it, for the climate is thoroughly suitable, and there is no reason whatever why indigo, fully equal to the Bengal dye, should not be manufactured. As regards to the growth of the plant itself, the conditions are far more favorable than they are down country. As every one knows, the greatest enemy the indigo crop has is rain either when it prevents the seed from germinating, or when, by persistent falls it absolutely washes the dye from the mature plant, and so diminishes the yield. In Bengal, Indigo often has to be sown three or four times ; and it is this susceptibility to excessive moisture, that gives it a bad name amongst the *zemindars*, who look on it as a *suberdust* crop. In the rainless tracts of, and below, Multan this danger does not exist, while the supply of canal water is ample for irrigation purposes. It would only need one glance at the magnificent indigo crops, now standing in these districts, to convince our readers that, as far as nature is concerned, there is no difficulty. The art, however, is not so satisfactory. Muddy water is used for steeping the plant ; the resulting infusion is evaporated in the sun—proceedings which involve a considerable admixture of grit, and a very great loss of colour. Consequently, we find that, while Bengal indigo sometimes brings in Rs. 400 a maund, that grown in the Punjab used to sell for Rs. 40! During the last few years, however, an enormous improvement in manufacture has been effected, with a corresponding rise in prices, and this year some consignments have actually reached a price of Rs. 140 a maund. With proper vats and skilled supervision, there is no doubt of what the result would be; and always providing that the lately raised scare about the discovery of artificial indigo is not true, we are certain that a factory on the Bengal plan would yield rich returns to any one who started it. As it is the *zemindars* are daily becoming more and more alive to the value of the industry ; and well they may since we believe it to be a fact in one village of the Mozaffargarh district where the total Government *jumma* is Rs 300 that the cultivators have netted between Rs. 7,500 and Rs. 10,000 on their indigo crops alone. In fact, what a few years ago was one of the poorest districts in the Punjab, bids fair to be one of the richest. This is of course most satisfactory both to the cultivator and to Government who, as the district has just been re-settled, will of course have taken these facts into consideration, and gain a corresponding increase of revenue.—*Civil and Military Gazette*

ASPARAGUS ON CLAY SOIL.

WHERE there's a will there's a way, and this is the best time to plant Asparagus. This sea and sand loving plant does not like a cold clay soil, and it may be (but should not be) a hard task to make a fine plant, wherefrom to cut fat sticks, on a soil that may be compared to wet putty in winter and Babylonian brick in summer. Before I became a Hermit the heavy undrained clay at Hermitage had never borne a crop of Asparagus, but as I brought with me experience of a quarter of a century of horticultural work on the worst soil that could be found in Stock Newington, I ordered a beginning to be made for Asparagus at the upper end of a piece of very wet grassland that sloped very slightly from the site selected towards the natural flow of the water. And the first step taken was to sow a bed in a sheltered garden a furlong distant, where we could not afford room for our bearing beds, the only object being to obtain plants to begin with. The rule determined on was to form two beds every year until a certain space was covered, each bed to be 4 feet wide and 60 feet long, on a foundation of unmitigated clay, a considerable piece of which was to be converted into a kitchen and reserve garden.

When your people understand you the wheels do not need greasing. If there is a bit of hurry you do not run against each other, and if an accident happens no one is in haste to utter a word that sounds naughty The faithful Tom sauntered up to the high road, and caught sight of a string of carts conveying the rubbish from some buildings that were in process of demolition, and with the caution of a Jew he asked, "How much," There was a bargain made instanter, and we had carted in, for "a mere song" (which I am now singing) a grand lot of this rubbish. It was knocked over, and the large stuff wheeled away as metal for roads, the woody stuff went towards the chimneys, and the mixture of plaster mortar, sand, and small broken brick remained as the raw material for the manufacture of Asparagus.

This stuff being laid in convenient ridges, the top spit of grass turf was taken off on a space 60 feet long by 14 feet wide, leaving an ample margin for two 4 feet beds and a 2 feet alley between. But the margin was none too much, as you will see. Then we brought to the spot all the old leaf-soil and cleanings of melon pits, and scrapings of turf from odd corners—a sort of indefinite infinity of all kinds of rubbish, but every bit containing something suitable to feed a plant. All these things—the top turf, the calcareous rubbish, the leaves, and the sweepings—were thrown together methodically and the mixture made a great raised bed, looking very grey and stony, except where chips of live turf stood out to make a few dots of greenness.

This being accomplished in the month of March, the new bed was at once planted with Ashleaf Potatoes ; while on the other side, in the sheltered garden, the Asparagus to follow the Potatoes was making a beginning of its noble career. The Potatoes were a grand crop, good in every way save that they were round in the skin ; and the only exhibition they were fit for was that which took place daily with the aid of a plate or a bird or it might be the only fair family blower

When September arrived and the "Taters" were gone, the new big bed was well stirred over, and some fat dung was laid in the trenches as the work went on. All being made tidy, the ground was pegged out to form two beds of 4 feet each with a 2 feet alley between ; and then we made shallow furrows for the plants. These were taken carefully so as to leave the seed-bed well occupied to furnish plants for the next year without need for another sowing. In planting we put single plants in their places and slightly covered them with the finest of the stuff near at

hand, and when this was done the earth from the alleys and outsides and ends was strewn over and amongst them, all lumps and stones being thrown out, and the bed was then raked over and the rows carefully trodden to fix the plants in their places.

As regards distances, we began with a line down the centre of each bed, and plants at 18 inches distance. From this each way was a line 15 inches distant and plants 18 inches apart. Thus, the two outside rows were 9 inches distant from the alleys, and the plants throughout were 18 inches by 15 inches apart, every one carefully singled in the process.

They were green when planted, and so continued for a month, when they were done brown and were cut down, and the work of the season came to an end in the laying on of a thick top-coat of fat dung that had been saved for the purpose under cover.

Early in the subsequent spring the ground was very carefully pricked over between the rows and very thin sowings of Radishes and Lettuces were made between rows. These were removed from time to time either as weeds or as crop. Where a Lettuce stood near an Asparagus crown he had to take flight along with a groundsel or a Chickweed, but enough remained to pay the rent, and came to perfection and did no harm. We did not cut a stick the second year, but we cut fairly the third year, and greatly the fourth; and, except for the circumstances that bring mundane things within finite measures might have gone on cutting our sticks for ever.

For three years we continued to lift plants from the original seed-bed to furnish the new bearing beds that were made each spring, and having borne a crop of Potatoes were planted with Asparagus in September. The management never varied, except that, as we found the growth very strong we gave the plant a distance of 2 feet in the rows still keeping to the 15 inches measure between them. A dressing of fat dung was put on the top after cutting down in autumn, and we soon learned to give another dressing in spring, which was peculiarly beneficial, and must have a paragraph to itself.

It is not the rule to protect Asparagus. Now, our lower garden at Hermitage was blest in spring with a strong supply of pure air from the hyperborean regions. When a frosty wind swept over the marshy meadows and slid through the rising grass like a flash of lightning with a razor edge, I used to notice that many a fine stick just rising would be cut off, and many that followed were flinty in their hardness, owing to the check to growth from the sudden onslaught of the east wind. And so I had a great sweep up made of all kinds of light rubbish. Rough grass was cut from neglected corners of the shrubbery, leaves and sweepings of the hay-loft were gathered together, and this light stuff was put over the crowns in little heaps. The rising sticks often lifted up the light protection in a lump, like the head of a Mushroom, and the sticks so protected were as green as needful, and very much more fat and tender than such as had to fight through without any such help. It became therefore the practice to save leaves and light litter for the spring dressing of the Asparagus beds, and the stuff was never put on until it was really wanted, because it might have been blown away, or might have quickened growth, which in so exposed a situation was not to be desired.

It is the custom, I observe, to put a crop of Cauliflower, or some such thing in the alleys between Asparagus beds. This, in my opinion is bad practice, allowable only in the first season, after which it becomes a profitless game of burning the candle at both ends. Those alleys should be kept clean and the outside rows of Asparagus will root into them and enjoy the range; therefore, to dig the alleys is to do mischief. Far better keep them open, for the roots to run below and for the cultivator to run above. In the course of his running he may find it expedient, as I have done, to stake his Asparagus beds with light brushwood to afford support, for when the top grass is snapped short off by the wind the growth of the next year's crop is prejudiced. Where frost and wind are unknown it will of course be waste of time either to protect or support Asparagus.—*Shirley Hibberd.*

AGRICULTURE AND COMMERCE IN JAPAN.

THE *Nichi Nichi Shinbun*, of 14th April, contains the text of an interesting memorial, purporting to be addressed to His Excellency the Daijo Daijin, by their Excellencies Okuma Shigenobu and Ito Hirobume, and detailing the grounds for the formation of a separate State Department to be termed the Bureau of Commerce and Agriculture. The following is a careful translation:—

"To effect a more complete reform in the conduct of departmental affairs, it is urgently necessary that all those sub-departments having control over husbandry and trade should be amalgamated into one independent department. Under the present system, all matters relating to agriculture and merchant shipping are controlled by the agricultural bureau and general post-office branches of the home department; those relating to commerce by the board of trade, a branch of the finance department; while no office in connection with industry has existed since the industrial board, a branch of the public works department, was abolished. On examination into what has been done by those bureaux, we find that the duties for which they were established, namely, to lay down systematic rules for the encouragement and protection of husbandry and trade, and to stimulate those industries without favour or partiality, have been made mere minor objects.

"This condition of public business must be altered; moreover, the present system of division under two chief departments is attended with inconvenience, an occasional duplication of business, and an increased expenditure as the following figures will show:—

	Yen.
Agricultural Bureau Expenditure	31[illegible]
Post Office	[illegible]103,364
Do. Marine Office	5[illegible],703
([illegible] Bishi subsidy excluded.)	
[illegible] of Trade	66,[illegible]17
[illegible] Office	81,941
Forest Office	200,000
Total	1,832,100

To which must be added expenditure on the Mita training establishment, agricultural college, and Shimosa farm, under the agricultural bureau, amounting to 142,793 yen, making a grand total of 1,976,901 yen.

"In Austria, husbandry, trade and public works, form one department; in Germany, France, and Italy, there is a special department for husbandry and trade; and in countries where there is no special department, the business is performed by other departments. From this it is clear that trade and husbandry are not less important than public works and other business. The postal service has become extensive, embracing international treaties, consequently in some countries it is an independent department; while in others it forms a semi-independent department.

"These are reasons why we recommend the formation of a new department, etc., etc."

(Signed) OKUMA SHIGENOBU, Sangi.

" ITO HIROBUMI, "

LOCUSTS IN AMERICA.

I HAVE had occasion more than once to refer to the destruction caused by locusts or grasshoppers to the agricultural produce of the States bordering the Rocky Mountains on the east. There cannot be the least doubt that these have some years done a fearful amount of damage, and are yet looked upon as one of the greatest bugbears to farming on the plains. In many districts there are various kinds of grasshoppers or locusts, which each do a trifling amount of damage; but the real migrating locust or grasshopper is the *Caloptenus spretus*, and is native to the high and dry regions of the Rocky Mountains. The best professional authorities place his habitat in the region between 43 and 5[illegible] degs. north latitude and 103 and 114 degs. longitude west Greenwich. Portions of this territory are said to be deserted for other places, but always somewhere in this immense domain they are sure to exist in considerable numbers. The conditions for their increase are dryness and warmth. With these conditions those that are spread over this vast region increase with amazing rapidity, and if two favourable seasons succeed each other they are sure to migrate. Professor Aughey, an authority on the subject, says that after they hatch out in the spring it takes about seven weeks before they reach their full growth. During this time they moult five different times, and each time change slightly in colour. Only at the last moult are full wings acquired, the thorax flattened, and the insect ceases to grow. Where now they cover the ground in their native haunts the scanty vegetation is soon exhausted, and they then manifest their peculiar instincts. They take short flights for several weeks, apparently to test the strength of their newly-acquired wings. The warm, pleasant days, with gentle winds, are their favourable periods for flight. When all is in readiness they rise from eight to ten o'clock forenoon, and move off with a rapidity dependent almost entirely on the wind, varying from three to about fifteen miles an hour. They do not move in broad sheets but in columns like fleecy clouds, from one to five thousand feet thick. They sometimes continue their flight through clear, warm, moonlight nights, but more generally come down between three and five o'clock to feed. On the following day they continue their flight if the weather is favourable. A change of wind or a fall of temperature brings them to the ground at any time. From their native habitat they move mainly in an easterly, south-easterly, and southern direction. Moving in this direction, those that migrate from Montana by the middle of July reach Nebraska and Kansas some time in August and September. They do not always deposit their eggs where they first light down; frequently they remain from one day to three weeks, and then move further on before egg-laying is commenced. The numbers that light down are often enormous. In Cedar County, Nebraska, in 1866, during July, they appeared in such numbers that the sun was darkened and limbs of trees broke down and bent by their weight. It was very difficult for one to move through the living mass. On the Union Pacific line of road the engine wheels and rails sometimes got so greasy running through a cloud of them as nearly to stop the train. Such cases are extreme and exceptional, but have occured at long intervals over limited areas. It has been no uncommon thing, however, for them to be so abundant as to entirely cover the ground. The female lays her eggs from middle of August to beginning of October. They are mostly deposited in high, dry, and somewhat compact ground. The number layed is simply enormous when the "hoppers" are thick. One authority says as many as 14,000 to 2[illegible],000 eggs to the square foot have been picked up. When severe frost comes on the old die off rapidly; at the appearance of permanent cold weather they have all disappeared. In some of the warmer portions of Kansas and Nebraska some of the early laid eggs hatch out, and are killed with the first winter cold. Again, warm weather in January or February may hatch out many more, which are also killed by subsequent cold weather. The usual hatching time is March and April, and, as already stated, as soon as the last moult they seem disposed to migrate. No exception to this rule is known on the plains. In Iowa, Nebraska, Missouri, Dakota, and Kansas they are disposed to return to their native domain in the Rocky Mountains. They, therefore, move mainly northward and westward. Their instincts seem to force them to the higher and drier regions where they originated. Such was, I understand, the case when countless millions left these States in 1876. In 1877 the spring was cold and wet, and a great many of them perished, and those which did survive seemed sickly and demoralised. These survivors first moved northward, then southward, and finally were seen to move in all directions, one column above another, moving in opposite directions. The greater part of this season's locusts evidently ran out by staying too long in a climate unsuitable for them. When the migrating locusts reach Kansas and Nebraska, the greater part of the wheat, barley, and oats are safe; corn and the gardens are the victims. If they come before the former is sufficiently ripened to resist their attacks, which is not always the case, a swarm of locusts can ruin a field of corn in a few days or even hours. Often the fields are only partially destroyed. Sometimes the silk and foliage are partially eaten off and the [illegible], so that the crop [illegible]

mature. If they leave at this stage all is well, and if not they deposit their eggs and so endanger the wheat crop next spring. The countless numbers that are hatched out in the spring become exceedingly voracious. As they soon commence to move by jumping in one direction, they are apt to devour everything in their path. This continues until they are old enough to fly, when they remove to other regions. Generally some corn can be saved in spring, and late planting may entirely escape. Sometimes the third planted corn during locust years yielded a fair crop. The cereal grains are, however, usually largely destroyed between the period of hatching out and flight of the locusts. No means have yet been devised for destroying the locusts on their appearance in swarms from the north-west. The injury they then do is, as already stated to the corn and gardens, and also to the fruit and forest trees. A great many methods are, however, devised for destroying their eggs, all of which are more or less successful, some so much so that some farmers have been known to save their crops, whilst others have had them entirely eaten up. The plans adopted are too numerous to mention here, but unfortunately the farmer only too often stands and looks on, and does nothing until his crop is destroyed. It requires energy and decision to fight them, but when it is properly commenced and persevered in it is successful. Owing to the sudden and extreme changes of temperature experienced on the plains locusts can never become localised on the *agricultural portions* of the prairie States. The spring of 1877 is a notable illustration of this fact. In March and April countless millions hatched out, then followed cold rains with extremes of temperature. In consequence, in spots which seemed alive with them previously not one could be found a few days afterwards. As a matter of fact they cannot do with a low altitude and moist climate. The amount of damage done by invasions of locusts have been usually over-estimated. There can be no doubt but that they did considerable damage in 1874,'76, and '77, but by no means as much as was currently reported. The drought, human indolence and carelessness, doing much more. There were men those years who never touched their corn after it was planted, and grew nothing but weeds, and blamed the locusts when these were miles distant. Sometimes there are many years between locust invasions, and it rarely occurs that a whole State suffers at once, while the small visitations are frequent. The destructive ones occur at long intervals and over comparatively small areas. One reason for the destructiveness of locusts hitherto has been the small area in the thickest settlements under cultivation. When the area of cultivation is trebled the damage will be much less. Another more important factor against their increase and destructiveness is the increasing rain-fall of the prairie states advancing with cultivation. It has been noticed how the wet spring of 1877 destroyed the greater part of those that appeared that spring. With extended cultivation the moisture of the climate is likely to increase, and the instinct of the locust will tend to keep it away from a climate hostile to its existence. While, therefore, the locust in the trans-Missouri region is extremely undesirable, it is by no means the pest that it is usually represented to be. Human energy and skill can to a great extent counteract its injurious effects. I have been mainly indebted to careful data collected and published by Professor Aughey for the facts in this article, but these have been largely corroborated by a great many old settlers I have met during my peregrinations over the Western States and, as I have had to refer to them oftener than once, and this point of locust is often made a very powerful argument against the prairie states I have thought it best to lay a plain and unvarnished statement of the facts so far as I can gather them, to show what this locust pest really means. As a matter of fact it can be neutralised to a great extent by protective measures, and is not by a long way the greatest drawback arable farming has got on the plains of the prairie States as any settler who has been here over the locust year will at once inform you. I had been led to look upon this locust plague as something awful, and delayed writing until I could get authentic information, which in a form, I have attempted to place before the reader.—*Glasgow Herald.*

COTTON PRODUCTION IN THE UNITED STATES.

THE Census report upon the cotton growth in the United States presents many facts of considerable interest, both of a commercial and geographical nature. The whole annual production of 5,757,257 bales is grown on 14,441,993 acres, limited to 14 States. Of these, the highest in rank is Mississippi, which produces over eight-tenths of a bale per head. It is generally considered that the special fertility of this State is owing to the large area of the 'Yazoo' bottom of the Mississippi river; in reality, however, only one-fourth (27 per cent.) of the cotton production of the State comes from this source, one-half of the whole being produced in what may be termed the first-class uplands or the little land-belt bordering the Mississippi bluff and the two prairie belts. The remaining one-fourth is grown in a scattered way over the sandy uplands, bearing more or less of the long and short-leaved pine, that forms about half the area of the State. Another reason of the exceptional yield of this State is the fact that cotton culture is the one pursuit to which the population devotes itself. The yield of the State is 955,805 bales, the average per acre being over three quarters of a bale, even with the imperfect tillage and incomplete picking of the crop that at present exist. Estimating the lands reclaimable by simple exclusion of the Mississippi overflows at only 3,000,000 acres, the annual production could be readily raised to 1,250,000 bales, without any change in the method of culture, in the Yazoo bottom alone. With improved cultivation the production could easily be brought up to 5,000,000 bales; and thus with a similar improvement in the culture, of the upland, the State of Mississippi could grow the entire crop now grown in the United States. Georgia comes second in the list, though her physical capabilities are very different from those of Mississippi, the first and second-class soils being very limited. With half a million more inhabitants than Mississippi, the cotton product of Georgia is only about half a bale per head and the average per acre two-thirds of that State. But Georgia owes her yield [illegible] bales, to better cultivation, the use of fertilizers, and the habits of an industrious population. Alabama (699,654) would stand hard in relative proportion of yield, but she is overstepped by Texas, which has an enormous area and is therefore enabled to assume the third rank in actual figures. Alabama is a newer State than Georgia, and, as her agricultural features are almost identical with the latter, it would be expected that there would not be so much difference in the yield; and the inference, therefore, is that while Mississippi is still within the period of the first flush of fertility, and Georgia has reached the stage when the use of fertilizers is renovating her fields, the soils of Alabama have passed their first stage, though her population has not yet realized the necessity of sustaining the powers of the soil artificially. Florida shows a low product of less than a quarter of a bale per acre, the land being mostly pine and cultivated without manure. Nevertheless the area of production has steadily increased and the population very largely so, though this is due more to the fact that the culture of tropical fruits has lately engaged the attention of capitalists. Tennessee (330,621) presents some curious features—viz., that her total production is less than half that of Alabama, but her average product per acre is one-half greater, and equal even to that of Mississippi. The explanation of this is that the cotton production of Tennessee is concentrated upon a comparatively small area of highly productive land, the rest being devoted in preference to grain, tobacco, grasses, and other industries to which the climate and soil are adapted, while in the other cotton-growing states, cotton is very generally cultivated as a matter of course regardless of all other industries. Arkansas produces 608,000 bales on about a million of acres, and presents nothing peculiar in her statistics. Louisiana (508,569) like Tennessee is engaged in other cultivations, and notably that of the sugar cane; but the rate of production of cotton is singularly high. The small parish of East Carroll in the north-east corner of the State, has the highest average product of any county in the cotton growing States (.95 of a bale) and this little spot is apparently the centre of maximum cotton production on natural soil in the United States, and probably in the whole world. Texas, although returning a yield of 803,642 bales, stands only 11th in rank in production per acre, partly to be accounted for by the accidents of the season during to the census year. The coast countries produce but little cotton while inland, between Red River and San Antonio, about 85 per cent. of the total is grown on black prairy land, the average product per acre on such land being 0.34 bale per acre. The Carolinas, which stand sixth and eight respectively, were the first of the original Union of Thirteen to place cotton culture upon a permanent foundation by adopting a system of regular returns to the soil, and the high product per acre as compared with Georgia and Alabama on the one hand and with Mississippi on the other, exhibits strikingly the tide-wave advancing westward, the ebb of the first fertility in Alabama and Florida, the rising tide of restored productiveness in the Carolinas, with Georgia on the westward slope of the wave on which it is rising and showing distinctly a higher product per acre in its eastern than its western portion, where the use of fertilizers is much less extended.

TEA AND SILK FARMING IN NEW ZEALAND.

SOME six years ago we directed attention to the island of Ceylon as likely to become an important tea-producing country in the future, and to Australia as a vast field for sericulture. Since then the strides taken by the former country in tea growing and manipulation have been simply extraordinary. This will be admitted when we mention that at the late Melbourne Exhibition the tea planters of Ceylon carried off 11 first awards out of a total of 49 bestowed, and altogether, they secured 36 honors for the 78 samples they exhibited, out of a total number of 270 awards earned by 506 samples shown by the various tea-producing countries. It is with a feeling of pleasure, therefore, that we congratulate our protégé of 1875 on having taken so distinguished a position in the great Colonial gathering of 1880 and 1881. It is not our purpose at present to re-direct observation to the progress of the sister occupation in Australia, although we understand that silk culture there has been fairly successful; but rather to allude to an important proposal, having for its objects the farming of tea and silk as a twin industry in New Zealand, which is at present being discussed in this country.

Practical persons have for some years been studying the scheme in all its bearings, and are assured that the North Island possesses many of the necessary advantages, and that the province of Auckland offers nearly all of them. There the temperature rises to between 90° and 100° Fahr. nearly every summer, with occasional leaps to 110°; the mean of the coldest month is 51°, and that of the warmest 68°. Snow is seldom seen except upon the mountain summits, and even slight frosts are a curiosity on account of their rare appearance or their evanescence. Moderate showers, spread over 180 days of the year, fall annually to the extent of 47 inches; the hot blighting winds and dust storms of Asia, so devastating to vegetation and so baleful to the silkworm, are unknown; and the mulberry, ailanthus, castor-oil plant, and numerous semi-tropical shrubs and trees flourish profusely in the open air. For China and Japan tea these advantages promise the perfection of climate, and the rarity of frost favours the belief that the indigenous Assam shrub might also be successfully cultivated. We have used the guarded expression that Auckland offers nearly all the advantages desiderated for tea and silk farming, the exceptional circumstance being the want of cheap labour. Were it proposed to cultivate and prepare either product by itself, we should feel pretty well assured that in no sparsely populated country, however suitable otherwise, could either tea farming or sericulture conducted separately pay. But pursued together on the same estate under the same general management by much the same staff of employes, the scheme assumes rather an inviting complexion. Indeed, if the economy likely to be effected by the efforts of a highly trained staff, using every scientific and mechanical aid to produce two or more important and valuable commercial articles instead of only one, be appreciated; if we bear in mind the moderate price of land generally in New Zealand, and Auckland's homogeneous and equable climate, so favourable to abundant and varied crops; if we recollect how trifling must be the expense of inland carriage to a shipping port in a country no part of which much exceeds 100 miles from the sea, as compared with the serious outlay incurred for transport by the tea and silk of China and India to the coast; if we give due weight to these advantages, and then reflect upon the enormous local demand for at least one of the products, the belief seems most reasonable

that the higher outlay for wages will probably be far more than counterbalanced by reduced expenditure in other directions

Several objects actuate the promoters of this enterprise, and their proposals may be thus epitomised :—" It is proposed to establish a syndicate with adequate capital, under the title, probably, of ' the New Zealand Tea and Silk Company (Limited),' for the judicious employment of capital and labour at the Antipodes by the acquisition of an area of say 80,000 acres in Auckland, or elsewhere in New Zealand, to be used partly for the land settlement of special classes of immigrants, and partly for the inauguration and prosecution of sundry important industries particularly those of tea growing preparation and sericulture, and, with the subsidiary design of offering agreeable and remunerative work to a great many females of education, who have been deprived through misfortune or fraud of their incomes, and of trying to improve the habits of the aboriginal population by engaging them in congenial employment whenever practicable." In explanation, we may say it is expected that one of the first results of the successful introduction of tea and silk farming as a combined industry into New Zealand would probably be a copious influx of immigrants more or less connected with the industries in question or with allied trades. For the accommodation of such, and in order that handsome immediate advantage might accrue to the syndicate, the acquisition of a much larger surrounding or adjoining acreage than would otherwise be necessary is proposed. It is suggested that portions of this reserve land should be sold, let, or used in the most profitable manner as the state of trade at the time might dictate, and on other parts selected farmers of ability and some means, with labourers and others of good character, should be settled. Food would thus be provided for the infant colony, and at the same time there would be a battalion of reliable assistants upon which to draw during any sudden crisis. In short it is suggested that, in addition to the functions of tea and silk farmers, the syndicate should assume those of a land settlement company.

The purely industrial feature of the scheme consists in the gradual plantation of an area of 8,000 acres with tea and mulberry shrubs at the rate of 100 acres or more of each per annum Simultaneously with this work, other products, such as olives, grapes, oranges, lemons, small fruit, honey, sugar, &c., are intended to be reared, all of which, being usually considered more remunerative than even the most lucrative crops of the ordinary farmer, would soon furnish a material item in the income of the syndicate. During the time occupied by the tea and mulberry bushes in arriving at a yielding age—in the one case four years, if from seed, and in the other two years if transplanted at five years old—the necessary buildings would be erected, the water services surveyed and arranged, water-wheels and other machinery constructed and the general cultivation and improvement of the estate attended to and gradually increased. In the course of the second year the first silk harvest would probably be gathered, and the net returns, if all went well might amount to £30 per acre for the yielding area of mulberries; a requital which as far as the leaf crop alone is concerned, would probably be doubled after the bushes had been five years in situ Until the fourth year there will be no appreciable income from the acreage under tea, and as this shrub has not yet been grown on a commercial scale in New Zealand, the promoters very properly think it better in the meantime not to hazard any opinion as to the probable return. But for the reasons already given united to the circumstance that the present large local consumption of 1,500,000lb. a year would render any export of the product for some years unnecessary, thereby effecting a saving in freight, commissions, and dock charges, they look for a very gratifying result from this source also.

To the philanthropic the intention of employing educated female labour in the more delicate manipulations is an appeal which has only to be known to meet with a hearty response. The successful employment of Maori workers, where practicable, would also be a philanthropic object well worthy a trial. But apart from this interesting, although a subsidiary, feature of the proposed undertaking, we think it may be said to contain the elements of success, and it deserves the careful consideration of those who are anxious for the development of our Colonies. Further information may be had of Mr. William Cochran, of Overdale House, Dunblane Perthshire, N. B., who is at present performing the duties of interim secretary.—*British Trade Journal.*

HAY-DRYING APPARATUS.

MR. A. PEEBLES, agent to the Duke of Northumberland, has drawn up the following report with reference to Gibbs' hay-drying machine on trial on his Grace's estate :—

I am requested by his Grace the Duke of Northumberland to communicate the results of our recent successes with the hay-dryer at Albury Model Farm. We have succeeded during the most unfavourable weather in securing our second crop of water-meadow hay in excellent condition. This is all the more satisfactory as the grass was young and succulent, and required a large amount of drying. Mr. Whellens worked the grass into cocks as quickly as possible, and when it was fair overhead these cocks were loaded into the wagons and passed through the machine. During the late heavy rains the grass was so saturated with moisture that much of it had to be passed twice through the dryer before it was fit for the rick. This occupied upwards of two hours and a-half for two tons of hay ; but if the water is well out of the grass, it will dry from a ton to a ton and-a-half per hour. Since we finished our rick Mr. S. R. Tristram, Q.C., has been using his Grace's machine to dry some very wet water-meadow hay, and is much gratified with the result. He had a quantity of old hay which was so much damaged by wet as to be perfectly unfit for food. I reported to you some time ago that part of this hay was put through the machine, which purified it from mould and dust, making it perfectly innocuous, and cattle and horses ate it at once. It was, however, dry and brittle, and was wanting in that aroma which is so desirable in good hay. I advised Dr. Tristram to mix it with grass newly cut, and put the two through the machine together. The experiment was tried yesterday at the model farm in the presence of a large number of ladies and gentlemen interested in agriculture. The hot-air blast purified the old musty hay, the green grass imparted a pleasant aroma, and the result was a fair sample of wholesome hay, which will be exceedingly useful during this season of short crops. The visitors expressed approval, and pronounced the experiment a success. From a detailed statement of expenses prepared by our farm bailiff, I find it costs 18s. per ton to make hay in wet weather, and about the same amount to purify damaged hay and mix it with new grass. The advantage of this process of converting mouldy hay into wholesome food cannot be overestimated, The reprehensible practice of making such stuff palatable by treacle, spicing, or steaming is a source of danger which subjects farmers to unforeseen losses. There can be but one opinion as to the value of making such stuff wholesome and palatable at the small cost of 18s. per ton, which includes hire of engine, fuel, and labour.

The rick of water-meadow hay we had previously finished under such adverse circumstances was examined, and the quality considered all that could be desired. These results are highly satisfactory, and demonstrate that in wet seasons these machines will be of immense advantage. One of his Grace's tenants, whose hay was spoiling in the field, is at present using the drier to save his crop before it is unfit for food. Our unfortunate experience of adverse seasons invests this subject with special interest to agriculturists, and speaks in forcible language in support of any means which can be adopted to secure the crops in our changeable climate.

CULTIVATION OF THE PINE APPLE.

THE cultivation of this valuable fruit, for which there is a gradually increasing demand in the markets of the United States and elsewhere, is a rapidly-progressing industry, and one which cannot fail to return considerable profit to the producers if proper care be taken in the selection of suitable tracts of land and a careful routine of culture be adopted.

The soil adapted for this industry is one which is best described as a gravelly loam, neither too much clay nor too much gravel, the first of which would render the ground wet, the latter too dry ; an intermediate one between the two is therefore desirable, and its value will be greatly enchanced if it contains plenty of decaying fibrous material. The pasture land at present in "ruinate" on the Liguanea Plains offers a most suitable soil, and one which is also to be highly recommended on account of its proximity to the largest seaport of the Island.

Commencing the cultivation with a piece of ruinate, the first work is to cut all bush, &c., and, if possible, have it removed from the ground without burning, as by burning the grass and weeds which are on the surface of the land will be destroyed, and we shall see that this is required in our method of cultivation. Having laid off the land in straight lines by placing stakes four feet apart at the ends and straining lines between them, we commence and hoe off all grass and weeds, arranging them in the centre between the first two lines, thus forming a ridge. After two rows are thus formed we commence with pick and shovel and loosen the ground to the depth of six inches in the centre space between the rows of weeds, and throwing half the soil thus stirred on the top of each row of weeds we proceed thus till the whole is covered, forming when finished ridges about 18 inches wide and 9 inches high with an interspace of 30 inches. After allowing a few days for the weeds and grass to decay in some measure and the ridge to settle the suckers may be planted. These should be selected after the bearing season is over, or indeed any time between October and January, if the weather is not too wet for planting. The lower dry leaves of the suckers should be removed to afford the small roots in their axils ready access to the soil, and then placed in the centre of the ridges to a sufficient depth to render them able to remain upright, to assist which they should be firmly rammed with a wooden rammer, leaving a small basin-like cavity at their base to hold sufficient water to solidify the soil and fix the plant firmly in its place. After the first or second watering no more is necessary unless a period of exceptional dry weather is experienced. The plantation must be kept free of all weeds, and the hoeings may be left in the trenches between the rows ; different kinds of vegetable refuse may also be placed there, and will benefit the pines by its gradual decomposition, as well as by the moisture it affords. Pines are not, however, as a rule benefited by large quantities of manure ; a little may be applied at times, but gradually, as it is apt to induce them to rot at the base and thus spoil many a fine plant. The best and most profitable kinds are the Ripley, Black Antigua, Black Jamaica, Charlotte Rothschild and British Queen.

P. L Simmonds, in "Tropical Agriculture," says that in 1873 the canned fruit shipped from the Bahamas was valued at over £14,000. Considering that these pines are, though much larger in size, considerably inferior to Jamaica Pines in flavour, it furnishes a fact worthy of emulation by Jamaica cultivators. The cultivation of this fruit in Jamaica is known to pay, and an instance is known to the writer in which the return, clear of expenses, for one acre has exceeded £80 per annum.

It is not intended by these specific instructions to convey the idea that the writer's method is the only one by which successful cultivation can be carried on, as no particular method of cultivation can, under all circumstances, be relied upon, and much must therefore depend upon the care and energy with which the industry is developed, and all failures, success, and other experiences turned to account. Planting on the flat, without any ridge, may be found in many cases to have a few points to recommend it, but, the writer's method, as before described is one which may be depended upon as supplying to the cultivator the main points which lead to success in the production of large and well-flavoured fruit.—*John Hart, Superintendent of King's House Gardens, Jamaica.*

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 22nd September, 1881.

S. H. ROBINSON, ESQ., V. P., *in the Chair.*

THE Proceedings of the last Monthly Meeting were read and confirmed.

The following Gentlemen were elected Members:—

The Superintendent of the Chumba State, Messrs. H Farer, C. S., F. W. Tytler, C. A. N. Walliob, Captain T. A. Freeman and Dr. C.N. Kernot.

The names of the following gentlemen were submitted for Membership :—

The Rajah of Bood, Cuttack,—proposed by Baboo P. C. Mittra, seconded by Baboo Joykissen Mookerjee.

Major W. Dalrymple, Cantonment Magistrate, Neemuch,—proposed by the Secretary, seconded by Mr. J. E. MacLachlan.

C. Y. Downing, Esq., Zemindar,—proposed by Mr. R. S. Pyne, seconded by the Secretary.

CONTRIBUTIONS.

1. Annual Statement of Sea-borne Trade and Navigation of the Bengal Presidency for 1880-81. Report of the Police of the Lower Provinces for 1880. Records of the Geological Survey of India, Vol. 14, Part 3, 1881, and Annual Report of the Royal Botanic Garden, Calcutta, for 1880-81. From the Government of Bengal.

2. Memoirs of the Geological Survey of India, Vol. 18, Part 3. From the Director.

3. Journal of the North China Branch of the Royal Asiatic Society, new series, Nos. 11 and 13. From the Society.

4. Plants of *Brownea ariza* and seed of *Pithecolobium saman.* From the Superintendent, Royal Botanic Garden.

5. A small collection of Orchids from Singapore. From E. Kock, Esq.

GARDEN.

A report from the Superintendent was read, of which the following are extracts :—

The garden has been considerably thinned of large and small trees as there are several other specimens, and the effect is, better light and ventilation; several other large and useless trees will be shortly cut down.

Trial germination of vegetable seeds per Sutton (English) and Buist (American) has been successful, all having germinated freely, the young plants look vigorous and healthy; a detail statement will be submitted in next month's report along with that of flower seeds when tested.

Both tanks are well supplied with water.

Angling.—Both tanks are well stocked with fish.

The garden can now issue *Musa uranoscopos* under English cost prices, and the following is description of the plant. This new Queensland Banana will form a noble ornament for a warm conservatory, it has a thick handsome stem formed, as in its allies, by the sheathing leaf stalks, which support large broad leaves not unlike those of *Musa ensete.* The flowers and fruits are borne in erect racemes, unlike those of the ordinary Banana, in which they are nodding—will flourish in the open in India.

Ficus diversifolia.—See the *Gardener's Chronicle* of 20th ultimo, page 247, figure 52. The garden has a small number of these plants ready for issue.

Members are advised that the garden is having accessions of plants daily, and as the same are in constant issue, it would be impossible with any degree of accuracy to keep altering the Catalogue, but by watching the proceedings, members can make out their requisitions accordingly. Orchids are not enumerated in the Catalogue as their value is averaged with cost of collecting, exchange, &c., and therefore fluctuate; but I can confidently say from what I have learnt from Members and others, whom I have supplied with these interesting plants, that the cost is astonishingly low. The garden stock of Orchids from Nepal, Shillong, Kossia Hills, Singapore, Burmah, Borneo, the Andamans and other places is extensive. Orchids from America and Australia are very expensive, and do not seem to thrive in India, so the cultivation of these plants is not continued in this Institution, as they only entail disappointment.

This report would be too lengthy if I were to enter into a very full detail of our plants, but at the present moment, I may say, it is rich in such plants as will thrive in the country with ordinary care."

A recommendation was submitted from the Council that Members be allowed to have fruit grafts to the value of Rs. 20 annually according to Catalogue rates, should they prefer them to ornamental plants. This rule to be tried for one year. Agreed to.

POTATOES.

Read a letter from Messrs. Wheeler Brothers and Lee of Ramgurh Estate, *viâ* Nynee-Tal, acknowledging receipt of a small quantity of Japan potatoes which were placed at the disposal of the Society by Mr. H. A. Firth with the view of trying them at Nynee-Tal. Messrs. Wheeler Brothers remark that "the season has now passed for planting them, but we incline to think that they will do very well here, as we raise some splendid potatos on this Estate, though we have not hitherto given a trial to the variety which you have sent. We will store those which you have sent us with our own seed potatoes this winter, and will carefully sow them in the spring, in a plot by themselves, and send you a report as to the result."

As bearing on the same subject a letter was read from Messrs. Lloyd and Co., respecting the consignment (32 maunds) of Melbourne potatoes received in February last, and alluded to in the proceedings of that month. "We can now"—observe Messrs. Lloyd and Co.—"give you the information you asked for regarding the Australian" potatos. The person to whom we sent them up to in Darjeeling, reports on them, as follows :—'The Australian turned out badly. Nearly all were rotten as Mr Leitch saw. All the pieces I thought good I planted at Helensburgh, except about 30 I planted above the Hotel : these latter all rotted. At Helensburgh 1 in 40 came up and of these the slugs ate several away at the root. Several rotted and had insects eating in them. I tried three boiling when they were new. They were not very tasty, *i.e.* not good flavour. The remainder consists of about 8 mds. of small potatoes which I think of setting in the Terai, unless you want them elsewhere.'"

TUBERS OF "CHUFFA," CYPERUS ESCULENTUS.

The Secretary placed on the table some tubers of the above grass, recently received in response to his application from the Director of the Botanic Garden, Adelaide, who thus writes respecting it in a recent report ;—*Chuffa or Earth Almond.* The American papers praise it, and say that for a few years after its introduction nothing was heard of it, except here and there as a curiosity ; but within the past year or two the interest in the plant has revived, and the Southern papers are advocating its culture. It is said that an acre of Chuffas will produce more pork than an acre of corn. The yield is said to be about 200 bushels to the acre. It is also still extensively grown in modern Egypt. The Chuffa dies down during winter. It is planted in rows *two and-a-half feet apart,* and *two tubers should be planted two feet apart,* and two inches deep. *It does not seem to do so well with us as in America.*"

It is also alluded to by Dr. Royle in his *Himalayan Botany* as follows :—"The aromatic principle being absent in the tubers of some species, while fecula is secreted in larger proportion, they are employed as food, as those of *Cyperus esculentus,* a native of the South of Europe, and of the North of Africa, and supposed to be the Malinothalle of Theophrastus. In addition to fecula these roots contain a fixed oil, which enables them to be formed into palatable emulsions, which, with the addition of sugar, have been employed as a substitute for coffee and cocoa."

The Secretary added he had also applied to Dr. Schomburgh and received from him some seed of the the Egyptian Pearl Millet," which is apparently our 'Bajra" (*Panicum spicatum*). A portion of the Chuffa tubers had been sown in the Society's garden ; the remainder (a very small quantity) is now available to Members.

JAPAN PEA.

Read a letter from Captain J. F. Pogson, forwarding an extract from an American paper (*Missisippi Patron*) respecting a prolific pea raised in Japan, and suggesting that steps be taken towards obtaining a quantity of this variety for trial in India, which was agreed to.

The following is the extract alluded to :—

Mr. T. E. Martin, and Mr. R T. Rutledge, both American progressive farmers, state that the "Japan Pea" is the most productive, as well as good food that they have ever grown for all kinds of stock ; horses, cattle, sheep, and hogs will eat the peas, stem and leaves if harvested before fully matured and cured like other hay, with as much relish as they do corn. Then there is no Pea for the table, soaked in water the night before cooking, that has a more exquisite flavour. They grow on a stout bushy stalk from two to three feet high, somewhat resembling the cotton plant. The main stalk, as well as the branches of the limbs, are literally loaded with small peapods, filled with little yellow peas similar in colour, size and flavour to the English garden pea."

As regards cultivation, they state :—"But the way to get the greatest yield is to plant in drills two and-a-half feet each way, allowing but one stalk to the hill, to remain after the first working. That will give you 6,960 stalks to the acre, and on ordinary land, cultivated the same as corn, will average at the lowest estimate a pint of shelled peas to the stalk, or a fraction over 108¾ bushels per acre. I doubt not that with high cultivation, and good soil, it would be an easy matter to double that yield, besides there is no other crops that will yield more hay to the acre. In fact I know of no crop so remunerative as the Japan Pea. It is a sure cropper, as clearly demonstrated by my experience with this season's crop. Neither wet nor dry weather materially interferes with the quantity or quality of the yield."

BAEL FRUIT.

Mr. R. A. Sterndale submitted an extraordinary cluster of Bael Fruit, nine in number, with the following particulars :—

"Baboo Hem Chunder Mookerjee of Jonai, a well-known zemindar of these parts, has just brought me the accompanying very curious cluster of Bael Fruit which I send over to the Society as a rarity.

The bunch consisted originally of ten Baels, but one got knocked off. On the same tree but almost out of reach is a similar bunch but larger. Baels, as a rule, grow singly or occasionally in pairs. I have never seen a cluster like this before, it resembles a bunch of gigantic green grapes."

Letters were read—

1. From Deputy Assistant Commissary-General, applying for a pound of tobacco seed for cultivation in the Andamans. Complied with and results of sowing promised in due course.

2. From Under-Secretary, Government of India, Revenue and Agricultural Department, requesting that in future a copy of the Journal be sent to the Department.

3. From Dr. Gustav Oppert, applying for publications of the society in exchange for the Madras Journal of Literature and Science.

4. From the Librarian, North China Branch of the Royal Asiatic Society, forwarding certain Numbers of their Journal and requesting an interchange of Publications. Agreed to.

MINERALOGY.

THE total quantity of gold raised in the Australian Colonies since 1851 amounted in 1879 to sixty-nine million ounces, valued at £271,000,000, by far the greater portion of which came from Victoria.

A COMPANY in Tasmania recently sent to Launceston a cake of gold of 1,202 ounces in weight, valued at £4,820, obtained from 776 tons of stone. Another crushing company sent 2,122 ounces from only 418 tons of quartz, or an average of over 5 ounces to the ton. When shall we hear of similar results from Southern India? With the prospect of having the rupee at one shilling and six pence, and with the knowledge that £3,400,000 has been locked up in the various companies, we may well ask anxiously.

THE Royal Commissioners on Mines are now engaged in carrying out practical experiments with the object of determining the best means of avoiding explosions. They have privately visited Wigan, and carried on a series of experiments with electric light. These, we understand, go to show that whilst the light might be useful at the foot of the shaft or in large clearings, it will not do for "getting" coal.

WE observe that the Government have taken the first step towards resuscitating the unfortunate Bengal Iron Works They have offered to take over the whole concern for a sum of three lakhs. The Company has spent over fifteen lakhs, so that if it be decided to accept the offer made by Government, a vast loss will have been sustained by the shareholders. It does not follow that the concern is worth fifteen and-a-half lakhs, although that sum has been expended, but experts agree in considering it worth much more than the amount offered by Government. If this be so, it is hardly worthy of a great Government thus to take advantage of the company's impecuniosity. The shareholders have asked the Government to reconsider their offer, and either to purchase the concern at a valuation, or assist the present company with money, or certain concessions, as the purchase of Government stores. It is a pity that a new industry of this important kind should be ruined for want of a little encouragement, or from want of capital, and Government might be a little more liberal in interpreting the phrase, "development of the resources of the country."

IT is strange that the Government does not seem to encourage the working of coal in the Mergui district. Many years ago, coal was discovered there by Dr. Helfer, and as far back as 1841, the state worked some mines on the banks of the Tenasserim river. The coal that was turned out was found equal to ordinary country coal used in sea-going steamers. It came out in good masses and burnt freely, but the iron pyrites in it were somewhat against it. At another place in the Mergui district, from 70 to 100 tons was extracted by a Burman, brought to Mergui, and delivered on board the Company's steamer *Pluto.* It proved to be a very effective and useful coal, keeping up steam well, and easily fired, of rather rapid combustion, and more adapted for tubular boilers than those of ordinary consumption. The Burman received Rs. 24 per ton at Mergui for this coal supplied to Government, I learn from the British Burma *Gazetteer*, and he was anxious to enter into a fresh contract for the supply of a further quantity at Rs. 16 per ton. As Government does not seem inclined to work the Mergui coal mines itself, and has not done so for so very many years, inducements might be held out to Chinese and Burmese on the spot to do so. I do not know what the British India Steam Navigation Company would be inclined to give per ton for coal at Mergui, but this might easily be ascertained, and as the steam trade between our southern districts, Junkseylon, and the Straits is assuming large dimensions, a local coal depôt at Mergui would be a very paying industry to start. The Chinese have long worked the tin mines in this district, which a European firm tried to do with improved machinery, and eventually discontinued as too expensive. The Chinese, however, continue their mining operations, and find them sufficiently remunerative. They would, no doubt, be able to make coal pay where a Government or an expensively conducted European corporation would fail, and it would certainly be as well to give people the chance of opening out a new industry like this, which we have had so long on our hands without doing anything to make it of public utility to the people and trade of the province.

AMERICA'S COAL SUPPLY.

AT a late meeting of the American Association, an interesting paper on the American coal supply was presented by P. W. Sheafer, of Pottsville. "The coal resources of Great Britain," Mr. Sheafer says, "are all developed now, and in process of depletion; while in this country, when our 470 miles of anthracite are exhausted, we have more than 400 times that area or 200,000 square miles of bituminous from which to supply ourselves and the rest of mankind with fuel. The coal product of the world is about 300,000,000 tons annually. The North American continent could supply it all for 300 years. With an annual production of 50,000,000 tons it would require twelve centuries to exhaust the supply. But with a uniform product of 100,000,000 tons per annum, the end of the bituminous supply would be reached in 800 years. What the annual consumption will be when this continent supports a teeming population of 400,000,000 souls, as will be the case some day, must be left to conjecture. But with half that population as energetic, restless and inventive as our people in this stimulating climate have always been, it is a very moderate estimate, guided by the actual output already reached in Great Britain, to suppose that there will be ample use for 100 000,000 tons a year of bituminous coal for home consumption alone. We have about 340 collieries, and produce 20,000,000 tons per annum, or about 60,000 tons each. Great Britain has nearly 4,000 collieries, and mines 132 000,000 tons, or 33,000 tons per colliery. Most of the anthracite mining in the United States is now done at a less depth than 500 feet vertical."

FORESTRY.

GOVERNMENT recently issued a Resolution to the effect that very little appears to have been done, in many places nothing, to put the hedges in order, in the Districts of Tanna, Kolaba, and Guzerat, and have ordered better attention to be paid to the condition of road-side trees.

A CORRESPONDENT of the *Pioneer* writes:—"In a recent article upon 'provincial expenditure,' you contrast the expenditure of the Madras and Bombay presidencies, showing that in the former the administration is much more economical than in the latter. The proof is complete as regards most items, but as regards the Forest Department I beg to take exception to your conclusions. In Madras, the forest management is lamentably inefficient, while in Bombay it is, I believe, tolerably efficient. The main object of the Forest Department is, as you say, to conserve the present forests, and to raise wood for the future. In Madras hardly any steps are taken for this purpose. There are, it is true, large teak plantations at Nilambur, and a few of the other forests are nominally reserved, but the bulk of the forests are left to themselves, and even many of the so-called reserves have not been demarcated. There is as yet no forest law for Madras. The Government of India forest law was not extended to Madras, because local legislation was proposed, but this has not been carried out. This is partly due to the misguided opinions of certain high officials who have now left the country, such as Sir William Robinson and the Duke of Buckingham. The former doubts whether forests have any effect upon rainfall, and the latter was willing to allow the forests of the Western Ghats on which the Cauvery partly depends for its supply of water, to be cut down because it would make the forest tracts more healthy. The fact is, that the Bombay expenditure pays for the conservancy of the forests and for the realization of revenue, while that of Madras is devoted almost entirely to the expenditure of bringing forest produce into the market. In fact, the forests in Madras have been so long neglected, that if the scientific system of management is introduced the departmental expenditure will have to be doubled, while revenue will be stationary for a year or two. In a few years, it may be expected to rise, and to recoup the additional expenditure as it has done in other provinces. Even if it failed, financially, the measure is imperatively needed on climatic considerations, as the important rivers that supply the irrigation works are deteriorating perceptibly every year, and a diminution in the rainfall in forest tracts is also perceptible. The Government of India have frequently remarked upon this subject. Let me refer you to some Proceedings of theirs quoted in the *Indian Agriculturist* of 1st August. I believe that the local Government are alive to the need of reform, and that it will not be long delayed, but I am anxious to prevent a misconception that may possibly be caused by your article above referred to."

AT a meeting of the Committee of the Agri-Horticultural Society of Madras, on the 13th ultimo, the following letter from Dr. Kirk, dated British Agency and Consulate General, Zanzibar, 4th June, was read:—"The Copal tree, of which I sent the seed, is, botanically, *Trachylobium hornemannianum.* The tree yields now an inferior or rather a second class varnish resin, but the same tree did yield the Animi resin, the highest priced varnish material in the world; the only difference being that the one is modern and the other has been buried for thousands of years under the soil, and there been changed. Still, I have clearly proved that the tree is the same in each case, and age is the agent that has so improved the value of the article. In many cases a change in the level of the land seems to have taken place since the old trees yielding the Sanifarini Animi died, for Copal is often found in the ground where the tree is now lost or rare. It is a fine tree of considerable size. I hear from Ceylon that plants of the Landolphia I sent you have reached the gardens from Kew; they were there grown from seed I furnished. Yours are the first in India, as Calcutta lost the seed I sent. I am now forwarding a second supply. I find the seed germinates easily, and it grew well at Kew; I do not understand its failure elsewhere, but it has failed certainly in most places, and I have applications for plants. I hope to get furlough soon, and shall not now ask you to send me a case of plants, as our dry season is coming on, and I hope to be off on leave before the next hot season. I shall always be glad to

do anything for you." The Committee recorded that from " the liberal supply of Oopal seed sent to the Society by Dr. Kirk, we have as yet raised only 62 plants, the greater part of the seed having perished before it reached Madras. The seed of Landolphia sp., to which Dr. Kirk refers, had also all perished before it reached the gardens. The plants we have were received from Dr. Kirk in a Wardian case in May, 1879, and nineteen of them are flourishing in pots and in the ground. Twenty-five plants were received, one was given to Dr. Bidie for the museum grounds, one to Mr. Cameron for the Lal Bagh, Bangalore, one to Dr. King for the Royal Gardens, Calcutta, and the other three died."

THE Vienna *Politische Correspondens* says : " The one famous cedar forest of Lebanon, formerly so extensive, has dwindled down to the dimensions of a mere thicket, numbering about 400 trees. To save it from complete destruction and preserve it at least in its present extent, Rustom Pasha, the Governor-General of the Lebanon, has issued a special ordinance, containing a series of stringent regulations calculated to check, if not quite to put a stop to, the Vandalism and carelessness of most travellers. It is expressly forbidden to put up tents or other kinds of shelter within the district of the trees, or to light fires or cook any provisions in their vicinity. No one is allowed to break off a bough or even a twig from the trees. It is forbidden to bring any beasts of burden, be they horses, mules, asses or any other kind of animal, within the district. Should oxen, sheep, goats, or other pasturage cattle be found within the prescribed limits, they will be irredeemably confiscated."

THE following is a startling account of the vagaries of an Australian acacia :—

A rich planter of the Nevada district—so the story runs—some time ago imported a number of saplings from Australia with a view to their acclimatisation. Among them was one, apparently belonging to the acacia family, which, however, grew far more rapidly than its fellows, and exhibited peculiarities of a somewhat startling description. For instance, every evening at sunset its leaves and the slender extremities of its branches rolled themselves up tight, and the whole tree, when any part of it was touched, however lightly, began to quiver violently, keeping up that abnormal exercise for as much as a minute at a stretch. Later on in its American career, it performed still more amazing feats. Its rapid growth necessitated its removal from the greenhouse, in which it had been accustomed to curl and shiver, to an open-air plantation. As it was being set in the fresh earth prepared for its reception, to the extreme consternation of all present, its trunk commenced swaying and its branches waving in a distracted manner, as though it were convulsed by pain and apprehension. Presently it emitted an odour of such power and pungency that the witnesses of this strange phenomena were quite unable to endure the stench, and promptly took to their heels. Since that achievement, it has been regarded with profound awe by the coloured folk of Virginia who are of opinion that it must be a supernatural being, or at least a nigger bewitched, the victim of some dread Obi enchantment. There is probably no soil in existence, save that of Western America, which is capable of producing anything like the effect above described upon the habits and disposition of a respectable Australian acacia.

A TANNER established at Dolores, in South America, draws attention in the columns of a French contemporary to the fact that Quebracho wood, when it is ground, rapidly loses the tannin it contains by exposure to the air, while the wood in logs preserves its tannin almost indefinitely without becoming impaired. He believes that the barks recently introduced into commerce, under the name of Quebracho bark, is nothing but the bark of the "Acacia curupy," which is a good tanning medium, but imparts a too decided colour to the leather. The bark of the Quebracho, which grows in the province of Corrientes, he adds, only contains insignificant traces of tannin, and is unsuitable for tanning purposes.

CALIFORNIA has hitherto been celebrated as possessing the biggest trees in the world, but the last Australian mail brings us a report from Mr. Clement Hodgkinson, which proves, if true, that the big trees of Victoria overtop those of California by about 100 feet. The startling announcement is made that the eucalyptus, or giant gum-tree, achieves in Victoria the immense height, in favoured situations, of 500 feet. The tree sheds its bark at certain seasons of the year, and appears in a coat of silvery glistening white, at which times the eucalyptus like stand rows of marble columns.

A GENTLEMAN recently had his curiosity aroused, while the trees were covered thickly with ice, as to the relative weight of the ice and the wood it surrounded. So he cut off a limb, and found it weighed two and three quarter pounds ; after the ice was melted, it weighed two ounces. Two hours later another trial was made ; at first the limb weighed four and-a-half pounds, after the ice was removed it weighed three ounces. Another trial showed a weight of thirty-two pounds, while the limb alone weighed two pounds.

OSIER CULTURE.—The subject of the periodical overflow of the Thames, and other rivers, upon which a good deal of public notice has lately been bestowed, should be the means of directing more attention to the possible improvement of wet ground in marshy situations by the planting of osiers, which, under the technical name of "rods" and " willows," are a merchantable commodity, regularly in request by the basket-makers, which will yield a more certain return, perhaps, than many agricultural crops that are subject to casualties arising from adverse seasons, the profit being very considerable, and the management comparatively easy and simple.

Nature, indeed, spontaneously suggests this application ; for the goat-willow, or sallow (*Salix caprea*), may often be found indigenous in moist ground, more particularly in those waste and marshy situations that are, under usual practice, so difficult to deal with. A two-year-old seedling plant of the goat-willow will often produce several shoots three or four feet high, and if allowed to grow longer still, and cut down every three or four years, no tree will produce so great a bulk of faggot-wood, for a well-established stock will sometimes give out in one year shoots eight, to twelve feet long, straight and well proportioned, some of them an inch in diameter, at a yard from the ground. Ultimately the goat-willow becomes a fine tree, often attaining a height of forty or fifty feet with a trunk varying from one and-a-half to two feet in diameter, and for hoops, poles, rods, crates, sheep-fences, and other purposes, the earlier produce of the goat-willow is extremely valuable.

But it is in the form of osiers regularly cropped, that can be grown upon land subject to tidal overflow, that a definite produce and consequent regular income can be relied on, and as there is a good deal of confusion existing as to the various species of *Saluxia*, we will briefly indicate them.

The green-leaved osier, or Ornard (*Salix rubra*) is strong and tough, and in request for carboy baskets.

The Spaniard, or Spaniard rod (*Salix triandra*) has several varieties, some very good, and others very inferior. The black-budded Spaniard is used for the bottoms, rims, and handles of large baskets. The Grey Spaniard comes in useful for coarse brown baskets. The Horse Spaniard is a very poor kind.

The old common osier, being soft, of course, and brittle, is not worth cultivating, in many instances ; but there are some varieties of the *Salix viminalis* that are extremely useful, and the good and the inferior ones bear such a close resemblance to each other, that the difference often cannot be detected except in the working. The best variety is known under several names, as those of the Snake osier, Brindled osier, Blotched osier, and Speckled osier. The Yellow barked osier is also a good one, while the Long-skin is of smaller growth, but has the good qualities of being heavy, firm, and tough. The Brown-rod, Brownard, or Silver osier (*Salix Hoffmanniana*), has a whitish hue on the under side of the leaf, eel baskets being usually made of this variety. The Gelsier partakes somewhat of the nature of the Spaniard, but is of more tapering habit, with a thick butt. The new kind (*Salix Forbyana*) is also akin to the Spaniard being equally strong, but more pliable in working. The Hollander resembles the new kind in its qualities, but is different in appearance, and these may be seen growing in large quantities on the Dutch coast. The Stone osier is a good kind, used for fine work.

The Blunt-leaved Ornard (*Salix Lambertiana*), the Bastard French (*Salix lanceolata*), and the Rose Ornard (*Salix Helix*) are very inferior, used only for fish baskets and hampers, their ends snapping in the working inwards and outward, which consequently makes inferior work ; but the Bitter Ornard (*Salix purpurea*) grows tough and slender, and, like all the other ornards, will grow in water.

The French, French-rod, or Real French has been imported from France, where it is much used in the manufacture of small ornamental baskets. On the Continent it is much in request by wine-coopers, who bind on their wooden hoops to the wine-casks with it.

The rods, or willows, as they are termed in the trade, comprise several varieties, as the Skit-willow, the Goldstone, or Hornrod, of which there are two sub-divisions—the Wire-hornrod, which is thin and tough, and the Waterhornrod, which is very inferior. The rods (osiers, &c.) grow best on strong and loamy soils.

And here we should remark that soil exercises as material an influence upon the growth of osiers as upon other crops, requiring a compact sub-soil that retains moisture, and thus they will not answer in strong clayey soils, which in summer become hard and dry ; for these crack, and the moisture of the land evaporates. The Spaniard, New kind, and French, sometimes answer very well upon light land, where the sub-soil is kept moist by land-springs ; but where the supply of moisture is imperfect, an osier plantation lasts a comparatively much shorter time, and requires renewing in a space of time varying from fifteen to twenty years ; but in land the best adapted for their growth, by the margins of rivers subject to tidal overflow, they will last for fully seventy years with occasional mending ; but on light land the osiers are smaller and shorter, and the crop less bulky than when grown upon strong loam

Upon the first formation of an osier plantation the ground should be well trenched to the depth of a foot and a half, and in light soil the sets should be planted in rows eighteen inches apart, and fifteen inches from each other in the row ; for where the supply of moisture is not continuous, the shoots are fewer and shorter, and it is in such situations that the smaller varieties suited for the manufacture of small baskets are grown, and there is an advantage in thus planting them close, for if more space were allowed, instead of drawing each other up long and slender, they would branch out and grow crooked and "clubby" near the stools.

Upon the soils better adapted for their growth, which is rich and continuously moist, they are planted at wider intervals for upon such they will reach a length of eight, ten or dozen feet, so that the rows should be placed two feet asunder, and the sets and a foot and-a-half apart in the rows. If these were planted as close as the former the result would be that, there not being room enough for the number of shoots that the stronger plants will throw out, a few of the leading ones would get very tall, and their growth would prevent the action of light acting upon the others which in consequence would become of inferior quality and not ripen their wood in the course of the season, which in this state would be soft and pithy, and consequently unfit for manufacturing purposes.

The action of light upon osiers is somewhat remarkable. In ordinary seasons they are of a yellowish brown, but they sometimes assume a dull

green colour. The willows in cloudy seasons are of a dull brown mahogany colour, but in clear seasons the shoots grow of a bright red colour.

The sets are cut from the lower part of the shoots, and are generally used about the thickness of one's little finger for the larger varieties. The small part of the rods would strike just as quickly, but they produce smaller shoots. The sets should be about sixteen inches long, and be inserted into the ground at about half their length.

In severe seasons, some of the plants will die, the most injurious weather to an osier plantation being when mild winters are succeeded by hard frost in early spring. The plantations will then require mending, which is done in the following manner. The longest and smoothest rods are chosen, which are cut from their butt ends in a slanting direction, and are thrust into the ground by the side of the dead stool to a depth of eight or nine inches. These are inserted as they have grown, without being shortened, for if this were done, they would be smothered by the shoots of the older stools, and by being inserted of their full length, they have the benefit of air and light for a considerable time, which enables them to establish themselves before the others grow high enough to overtake them, when the summer will be considerably advanced.

Osiers may also be grown upon springy land. That is sometimes met with near the bottoms of elevations, the slopes of which are kept moist by the drainage of higher lands; and although such springs might often be cut off and drained by means of a few deep drains, aided by auger holes driven down into the porous watery strata which form their reservoirs, by the method known as the Elkington system after the name of the farmer who first practised it, such drainage is very often left undone; and there are many waste spots upon which osiers could be profitably cultivated, which would prove a source of profit to owners or occupiers of land, that are frequently entirely neglected and overlooked.

Osiers can be cut any time between the fall of the leaf and the rising of the sap in the spring. And although they are often cut before and after this time, it is not good practice to do so—especially when cut late in the spring, as it weakens the succeeding crop.

According to the accounts which have been published, the osier grounds upon the estate of Holkham that are planted with *Salix viminalis* commence their profitable return the second year after their formation, the first crop averaging £34 17s. per acre, after which they are cut down yearly and realise about £37 10s. per acre; these figures furnishing a strong argument in favour of the plan now recommended for more general adoption.—*The Farmer.*

EFFECTS OF LIGHTNING ON TREES NEAR A TELEGRAPH WIRE.

SOME instructive facts in this connexion have been brought to light by M. Montigny, in a recent examination of poplars bordering part of a road in Belgium between Rochefort and Dinant. The part in question is some 4,000 metres in length, and runs westward; it is level for some distance, then rises gradually to a height of 61 metres, through a wood, traverses a wooded plateau 200 metres in extent, then descends, still through wood, to a plain. A telegraph wire runs near the row of Virginia poplars on the north side, and it appears that, out of nearly 500 poplars forming this row, 81, or a sixth, have been struck by lightning. Hardly any have been struck in the other row. The trunks have been mostly struck on their south side and nearly opposite the wire. Comparing different portions of the road, it is found that in the horizontal part none of the (129) trees show injury from lightning, or at most only one (a doubtful case), but as the road rises through the wood the cases quickly multiply, and on the wooded plateau as many as nine out of 14 trees, or 64 per cent. have been struck. On the slopes the proportion is 25 per cent. M. Montigny distinguishes three kinds of injuries—(1) the bark torn and detached on a limited part of the trunk; (2) a furrow, straight or (rarely) spiral, made on the tree from near the wire, down to the ground; and (3) a peculiar oval wound, with longer axis vertical, and lips coloured light brown. Now, the furrows, which are probably due to the most violent discharges, are relatively most frequent on the plateau and on the western slope, which the storms usually reach first. M. Montigny is of opinion that the lightning, while provoked by the wire, does not strike this first, then the tree, but strikes the tree directly. His conception of the process is to the following effect:—Suppose a thunder-cloud charged with positive electricity. A long telegraph wire under it, though insulated, may acquire as great negative tension in the nearest part as if in direct communication with the ground, and the tension is greater the nearer to the cloud. While the inductive influence affects the wire most, near objects, such as trees, share in the influence according to their conducting power. The lightning attracted in the direction of the wire, yet does not strike this, the insulating cups presenting an obstacle to its prompt and rapid escape. It finds a better conductor to earth in a neighbouring poplar, wet with rain. From the facts indicated it results, that of two similar houses, one built on a plain, the other in a wood, and having a telegraph wire fixed to them, the latter is the more liable to injury by lightning, and the danger is greater if the wood enclosing the house be upon an eminence.—*Times.*

TIMBER IN BRAZIL.

WITHIN an area of half a square mile, Agassiz counted 117 different kinds of wood, many of them admirably fitted by their hardness, tints and beautiful grain, for the finest cabinet work. The [illegible], tortoise-shell wood, undoubtedly the most precious wood in the world, is found in large quantity on the tributaries of the upper Amazon, where the water can be most easily applied as motive power. The pao de sangre, the rosewood, the pao deferro (iron wood), or *Apuleia* [illegible], the various species of jacaranda known to natural history [illegible] under the name of *Dalbergia nigra Macharium* [illegible] and *Platypodium elegans*, the white and black [illegible], the [illegible], the pao santo or holy wood (*Kielmeyera*), and the sabucrana—both of which are rivals of the most beautiful walnut—are wasted yearly on the Amazon in amounts ample enough to veneer all the palaces of Europe. Maurice Maurie, the explorer, believes that with the facilities which the Brazilian Government is ready to impart to enterprising industry, the export of these commodities would develop immense profits in the shortest time, while the capital invested need not be enormous.

It is only necessary that these woods be introduced into the market to obtain a decided preference over those now most sought after in the two hemispheres. Still richer is the country in timber for the purpose of construction. The scapu (*Vouacapoua Americana*) is most plentifully found there, and often in the most imposing proportions. Mr. Maurie has seen dining tables six feet in width made wholly out of one piece. The wood, like all its kindred, macarandnba and itauba, or stone wood, furnishes ship timber as durable as teak. The longer these remain in water the stronger and harder they become. The former will compare the more favourably with the teak, inasmuch as it is more compact. A pistol bullet which will pass through an inch board of teak wood will not penetrate half an inch into a board of scapu. The itaubatree, too, offers many advantages over teak; it branches off naturally into keels and ribs of any size, and is lighter and more resistant.—*Journal of Applied Sciences.*

GARDEN.

THE number of fruit trees in Bohemia of all sorts, but chiefly, apples, appears, from some recently published statistics, to amount to 14,000,000. Of these, 10,000,000 are in gardens, 1,600,000 in waste lands, and about 2,000,000 on the sides of the public roads. The number of young trees annually planted is about 1,500,000. Between 6,000 and 7,000 miles of road are planted with fruit trees, mostly of the best sorts, and the revenue therefrom is very large. The fruit is largely exported to the north of Germany and Russia.

THE Vienna *Vaterland* reports that the gardener attached to the Palazzo Ferentino, at Naples, has, after the labour of years, succeeded in raising camellias having a distinct and fragrant perfume. The perfume is described as resembling somewhat a mixture of jonquil and pythosphorm, and as being very delicate. The flowers themselves are of a tender pale rose tint, and it is only in flowers of this colour that the agreeable fragrance has been hitherto obtained, although the gardener has endeavoured to impregnate white camellias with it.

FLORIDA ORANGES.

THE orange culture in Florida amounted to little or nothing before the war. Northern industry and methods have found their way into the State since, and given this cultivation a remarkable impetus. Ten years ago even the product amounted to but little. Now it brings millions to the State, and its increase for the next ten years can hardly be estimated. General Cameron was taken lately by ex-Senator Yulee, a friend and former associate, who represented Florida in the Senate thirty-five years ago, to see the largest orange grove in the world. This was the first time they had met since Mr. Yulee left the Senate for the South in 1861, and the renewal of the friendship between the two has been one of the pleasing incidents of the stay in Florida. A little later the train dropped us in the midst of 75,000 orange trees, covering over 400 acres of ground. A perfect wilderness of orange trees, apparently not cultivated with care, certainly not planted regularly, but just as nature had sown the wild seed. The wild luxuriance of nature had however been curbed by man, who in pursuit of wealth had turned vine ar into money, and, by grafting on the sour trees the finer sweet varieties, had snatched from the wilderness an income of over 40,000 dols. a year. General Cameron rambled with us over the place, all of us plucking the golden fruit *ad lib.*, and imagining ourselves in the veritable Garden of Eden—earth, air, and sky, soft, balmy and ethereal, combining to fix the allusion, and we were only brought back to a realisation that we were fifty miles from our hotel by an exclamation from one of the party "By Jove, we're lost!" This fact soon became apparent to us all, and just think of it—you who are bound by bands of thick-ribbed ice—lost in an orange grove in Florida! General Cameron enjoyed the joke, and busied himself eating the fruit plucked with his own hands. Many of the trees were laden with fruit of immense size and beautiful colour, although much of the crop had been gathered. One of the tempting sights in the grove was the grape fruit (*Citrus Paradisi*), of great size and beautiful lemon colour, and said to be the forbidden fruit of the Garden of Eden. It is useless except to look at and for preserving, although it is eaten by some. It has a sour, insipid taste. Lemons of immense size, growing upon small trees, now and then dotted the orange orchard. After an hour spent in looking over the grove, we, one by one, found our way back to the packing houses, where the superintendent told us that 10,000 boxes of oranges had been shipped this season from one half of the grove over which we had been rambling; that means 1,800,000 oranges, for which the owner had been offered 15,000 dollars while the fruit was on the trees.

"How many years does it take for an orange grove to come into bearing?" I asked the superintendent. "Eight years from the seed, and about five years if grafted or budded on to the wild fruit. That is, I mean to say they will bear in eight years from the seed, and in five years from the graft. They constantly grow [illegible] and bear more oranges [illegible]. No one can tell how long the tree will be [illegible] certainly [illegible] years."

People [illegible]

to 4,000 oranges, but there is a great deal of fancy in this statement and the truth is marvellous enough.

THE CULTURE OF HYACINTHS IN POTS.

THE time for potting or planting these popular roots is approaching, and a few remarks on the best way to treat them will now be seasonable. Should the grower choose his own bulbs, and be at the same time a tyro in the art of bulb culture, it will be beneficial to him to learn that extra size or largeness of the bulb is no safe criterion of the excellence of it. It may or it may not be better than a smaller bulb, but the balance of the chances are against it being so. The great difficulty in getting large bulbs thoroughly matured will always operate against their turning out superior to small bulbs The best test is not size, but solidity and weight. The former quality is easily ascertained by trying the firmness of the individual bulbs, small or large, by means of pressure with the fingers. Those which yield to pressure, especially at and around the crown or top of the bulb, should be rejected—they are not ripe, and those which weigh light—a point which can by practise be ascertained by balancing the respective roots in the hand, or better still by weighing them by means of scales—should be rejected. The heaviest roots, taking relative size into consideration, should be chosen; even if the smallest may by these tests be the heaviest and firmest; let there be no doubts about preferring them; they are certain to give the greatest amount of satisfaction.

The next most important consideration in the culture of hyacinths in pots is the soil or compost in which they should be grown. It ought above all things to be rich and light. It may be made up of the following :—One-third leaf mould, one-third rotten cow manure, and one-third fibrous loam, mixed and laid up where it may be protected from rain a couple of months before being required, though it may be, and often is, used immediately after being mixed.

A good proportion of sharp river sand may be added to this compost, when it is brought to the potting bench for use. The most useful size of pots for general purposes and for single bulbs is five-inch; yet if they may be wanted for room decoration in smaller pots, they can be grown very well in four-inch or even three-inch. In these small pots, however, they will want more careful attention than in larger ones after they have filled the soil with roots. It is important in potting to avoid burying the bulbs deeply. The top of each should be just level with the surface. Those that are to be forced early should be planted as soon as they can be obtained, while the principal batches should be potted in October. When potted, place them on a bed of coal ashes and cover them with the same or with cocoa-nut fibre or sand to the depth of four or five inches. In four or five weeks from the time of potting, they may be taken out of the plunging material, and placed in a cold frame. A selection of as many as may be wanted for a first batch may be made from the best rooted, and placed in heat at once; and from time to time, as wanted, they may be so drawn upon to keep up a good supply for all purposes. In severe frost the stock in the cold frame should be protected sufficiently to prevent the balls from being frozen through; but in all sunny, bright weather the frame should be freely ventilated in order to keep them slowly moving. When they are brought into the forcing house, place them as near the light as possible; give manure water liberally, and on all favourable occasions—that is, when the outer air is mild, let them have air freely.

To grow hyacinths in water, single varieties are preferable to double ones, because they are unusually better in spike and are also, as a rule, more free to grow. The very best roots also ought to be selected for this manner of growing hyacinths. Those who have not attempted their culture in water will find it very interesting. Having procured the roots and the glasses, let the latter be filled with pure water to such a height that the base of the roots will just barely touch the water. Before placing the roots put one or two small pieces of charcoal in each glass, to aid in keeping the water sweet and pure. The roots may then be put in, and the glasses removed to a cool dark cellar, or any other place in which they may be kept dark and cool in a dry atmosphere. Here let them remain for a month or five weeks, or till they have sent their roots down to the bottom of each glass, but examine them occasionally to see that all is doing well. Should the water evaporate quickly, so as to leave the roots bare make it up at once. It may also become foul and injure the roots, in which case they should be taken out, the glasses be emptied and well cleansed, and refilled with pure water as before and the roots replaced carefully. Fungus sometimes attacks the bulbs when grown in water, and will injure them if not brushed off in time. When this disorder is persistent and troublesome, dust the bulbs over with sulphur. When the roots have grown to the bottom of the glass, or nearly so, the glasses should be brought to the light gradually, and when they have become quite inured to the change, let them stand close to the glass, give plenty of air, but avoid cold draughts. As the flower stems expand they will need support, and the best way to secure this is to obtain the prepared hyacinth supports in brass or japanned iron which are usually sold along with the glasses.—*N.B. Agriculturist.*

THE HYACINTH, THE TULIP, AND THE GLADIOLUS.

THE ground should be well manured and trenched or deeply dug in the latter end of September. The best time to plant is October; any time during that month. Take advantage, therefore, of a dry day and a dry state of the ground to do the planting. The crowns of the bulbs should be not deeper than six inches, nor shallower than four inches. Nor should they be planted thinly, about six inches from bulb to bulb being the most that should be allowed between them, if a good solid display of colour is wanted. It is a point of some importance to have the bulbs all one depth in the soil, the flowering will then be more uniform, therefore let them be either four, five or six inches deep, but all one depth or the other. When the planting is finished, cover the surface of the bed or border with a few inches of [illegible] manure, out of which the rankest of the litter has been shaken. [illegible] firmly and equally all over the surface, [illegible] In spring, as soon as the leaves have [illegible] remove the manure. If the weather is [illegible] plants uncovered; but in the [illegible] lightly over them at night [illegible] positions they will be the better of a breakwind of mats or any similar fabric fastened to stakes and placed on the windward sides of the beds or borders when they begin to throw up their flower stems. It is recommended by some to lift and preserve the bulbs, after they have finished the flowering with the view of using them for next season's planting. Our own experience is that the game is not worth the candle. The roots may certainly succeed to the extent of giving a fair supply of flowers for cutting from if that is wanted, but they are not fitted to make a brilliant display in bed or border. For the purpose of cut-flowers, they may be grown in a dry, warm position, planted, thickly—standing root to root will not be too thick—and cut when their flowers are sufficiently expanded. But for the purpose of keeping up a good display in the flower garden, there is no more satisfactory way than making an annual purchase to the extent required, which need be down at comparatively small expense.

TULIPS.—These may be treated in precisely the same way as hyacinths in all respects except the depth of planting. They should not be planted deeper than three inches, and should be covered with stable manure to the same depth as the hyacinths. They may also be planted somewhat thicker, or about five inches apart each way. As they ripen their growth better than hyacinths in our climate, they may be lifted and replanted annually, with better results. When they have finished flowering and their foliage begins to decay, they may be lifted and laid in a sunny spot in sand, kept moist till they have lost all their leaves, when they may be stored away in dry sand in drawers or on shelves, till planting time. Only the best should be planted, so that the display should be as bright as possible, and the deficit in the numbers be made up by purchase.

THE CULTURE OF GLADIOLUS.—There are few more gorgeous yet graceful summer and autumn flowers than the various *sword lilies* or gladioli. The varieties known as gandavensis hybrids are those most to be relied on to succeed well in our Scotch climate. For early summer flowering they should be planted in October or November. Treat them in every respect like hyacinths. Prepare the ground liberally, and plant about four inches deep, and about some distance apart, bulb to bulb, but not less than nine inches between the lines. In cold, wet localities let planting be deferred till spring; but as this can only result in late flowering, the bulbs wanted for early flowering should be potted in December and placed in cold frames to be kept as cool as possible, only they must not be exposed to frost, which would kill them. These may be planted out in April, taking care to disturb the balls of roots as little as may be in transferring them to the open ground. Those intended for autumn flowering should be planted in February or March, according to the condition of the weather and the soil. On no account plant in wet weather or when the soil is wet. Prepare the latter by trenching deeply and manuring well. Plant as before described. Covering with manure is not essential, but will be found beneficial, although more as a protection from summer's drought than spring frosts, which will hardly penetrate to such a depth as to injure the roots or growth. It is important to give early attention to gladiolus in the matter of staking, otherwise the young growth in windy positions is apt to get broken before the flower stems expand.—*Gardener's Chronicle.*

TEA.

TEA cultivation in Ceylon is now attracting attention, and is making headway in the colony. We see no reason why it should not pay in Natal. It is already grown here, and succeeds on a small scale. We made a trial recently of the Natal product, and to our taste it is preferable to the Assam we are in the habit of using. It is strong, and like all Indian teas, does not do to be infused long. We to-day publish an article on the subject by a practical Indian planter, who is confident that under efficient management, tea growing in Natal is a branch of industry that will yield a very good return on the capital that may be invested in it. Several parties are already growing a few plants, and they all agree that they are well suited for Natal, and that they would persevere if only they could get leaf manufactured. Heat and moisture, with soil that retains water, are desirable. We commend our correspondent's remarks to the attention of our readers, and our columns are freely open for discussion on the subject. With sugar an established success, were tea proved equally so, there is no limit to coast industry, whilst abundance of suitable land is still procurable. The local Cape and South African markets would consume for some time to come all that is likely to be raised here at prices more remunerative than for export. Natal last year imported tea to the value of £6,264, and the year previous £9,793, whilst the returns from the Cape Colony aggregated in 1878 1,252,850lbs, and in 1879, 879,599.

JOHORE Tea has been characterised as "Good blackish leaf, strong Pekoe flavour." This, to begin with, is encouraging, and it may be that at no distant day we may see tea plantations on the Malay Peninsula. The experimental tea gardens belonging to H. H. the Maharajah are flourishing excellently. A tea planter from India, who recently visited them, stated that the "soil and climate was all that could be desired" for the successful cultivation of the tea plant. Samples sent to London have been reported on as above, and valued at from 1·7 to 2·1 per pound. Indian teas are increasing in favour, the deliveries in London reaching nearly 50,000,000lbs. annually. Apart from the export trade, Messrs. Thomson, the Tea Brokers, state that the deliveries of China Tea are about 116,000,000lbs. The quality has deteriorated. Java Tea is not esteemed in the home market, and the

same may be said of much that is exported from Japan. There are thousands of acres in Johore admirably suited for this industry, and judging from the quantity and quality of Gambier leaf and the general super-abundance of foliage everywhere on the territory, there seems to be nothing wanting to guarantee success to the planter except cheap Indian labour. The nearness of Johore to the Singapore market is in itself a great advantage to the planter.

WITH the exception of one million pounds to Canada and half a million to England, all the Japan tea exported was sent to the New York market during last year.

The Lekin Taotai (P'an) recently issued a proclamation in the city, suburbs and settlement, relating to the manufacture of of "lie" or spurious tea. This proclamation was issued on the 26th ultimo, but did not make its appearance in the settlement until a few days ago. Even now we are unable to get a fair copy thereof owing to the same having several of the Chinese characters obliterated. As far as we can make out, the substance of the proclamation is pretty much as follows: "It having been ascertained that spurious tea is being manufactured in this place, and whereas the larger portion of the revenue of this port is derived from the duty on tea, it is not fitting or proper that spurious tea should be made. It has come to the notice of this office (Lekin) that unscrupulous dealers, brokers, and others have manufactured largely thereof to the great injury of respectable merchants. Guards have been despatched to the various stations to seize all spurious tea and to strictly examine all tea brought down from the country. At the East gate of the city, the lekin guards seized a quantity of the article in question, and at another place (name not given) nine loads (piculs ?) were seized, which upon examination proved to be false tea. All of the spurious tea seized was ordered to be confiscated and burnt, Should no rigorous measures be adopted, it is hard to tell how far this illicit traffic might extend, causing thereby great injury to merchants and others. Orders have been given to redouble the guards, and to exercise the strictest vigilance towards suppressing this evil, and it is necessary that proclamations be issued for the purpose of warning the soldiers, carriers, tea dealers, and others against dealing in spurious tea. This traffic is not to be allowed, and as a warning this proclamation is issued for the information of every one. Should, after this, any one be found to disobey this warning, not only will the spurious tea be confiscated and burnt, but the party so transgressing will be detained, and sent in to this office for punishment."

THE returns of tea cultivation in Madras are very small, but the success that has so far attended the efforts of enterprising people, has induced many to take to it. Tea is grown in three districts of the presidency, namely, in Madura, Malabar and the Nilgiris; in the two first named districts there are only five plantations, but on the Nilgiris there are 79. The total average of land under tea is returned at 2,573 acres against 9,123 acres of land taken up; the acreage of land with immature plants is returned at 1,705. The approximate yield of tea of all the estates is returned at 649,460lbs, the cost of cultivation varying from Rs. 50 to 200 per acre.

COFFEE.

COFFEE prospects in Ceylon are not bright this year, and from Brazil we also learn that the crop will not be a very good one. Ceylon has suffered much from this cause, and the uncertain nature of the weather is frequently advanced as the cause. We suspect, however, that the real cause is impecuniosity, and the consequent necessity which exists for working cheaply. If we desire good crops for a long succession of years, we must nourish the land, and the soil and climatic conditions of Ceylon are so favourable to cultivation, that this point has been neglected. It has been thought that because the land has hitherto been so generous, it would always prove so. If the present depressed state of the industry leads planters to see this, shareholders will not have suffered in vain. The tea industry is now recovering from a panic of a similar nature. The prices obtained in London in many cases did not cover the cost of production. This led to a thorough investigation into the cost of manufacturing, and planters gradually found out what we have all along insisted on, that eight annas per lb. ought to be the maximum cost of cultivating and manufacturing. Now that prices have somewhat recovered, they will be in all the better a position to benefit by the more favourable market.

THE *Lucknow Witness* tells us that "a horse-race was won the other day on the Saratoga track in America by the free use of coffee. That is, instead of giving the horse spirits of [illegible] as is common, a quart of coffee before the second heat [illegible] before the third enabled him, though he was out of sorts [illegible] the first heat, to win the other two." If we must have a [illegible], argues our contemporary, let it be coffee or tea, rather than [illegible] and dangerous alcohol.

THE Madras Government, at the request of the planters of Wynaad, have been pleased to extend the provisions of the Coffee Stealing Act to the low land tracts traversed by the coffee in transit to the coast, *i.e.*, along the main roads from Wynaad to the coast. The Government are desirous of giving as much protection as they possibly can, and have requested the Collector of Malabar to report, if the concession made is sufficient. It is thought that the whole district should be thus protected, and not the roads alone, and that a form of pass should be obligatory, the pass bearing a stamp to cover the expenses of the additional protection afforded the coffee thus entailed upon Government. The suggestion if practicable is a good one, and moreover shows the authorities that the planters are prepared to pay for the protection given their industry.

MON. P. J. VAN MAANAN of Java offers an invention to the public for drying coffee by a mechanical process. Planters must have felt the extreme difficulty of getting the parchment dry enough either for transport or storage during wet weather, and the coffee moreover loses both in color and taste by being kept in a damp condition for days together waiting for the sun to appear. This invention, which is well spoken of by the Commercial Association at Samarang, offers to render the coffee planter independent of the weather, in preparing his produce for shipment, and if it really does this at a moderate cost, it ought to be invaluable in some localities. The cost of the machinery is stated to be £200, and it is warranted to dry from 50 to 100 piculs of coffee in 24 hours at an insignificant expenditure of fuel and labor. We shall publish any further information we get on the invention as soon as it comes to hand.

A WAIL comes from the coffee districts around Palghaut. Young estates in this neighbourhood enjoying all the conditions for successful cultivation, soil, good climate, everything that can be desired, elevation suitable, and rainfall perfect, are attacked in the most unaccountable way with leaf disease. The young wood which gives promise of excellent bearing capabilities for the next year, is suddenly denuded of foliage, and the wood itself dies back to the primaries, all in the short space of a fortnight. No apparent cause can be assigned for this rapid progress of the disease. Everything is being done to counteract the disastrous effects of the disease, especially vigorous manuring, and time alone will decide whether the estates will bear the attack or succumb.

LEAF disease, this year, in Coorg is generally pronounced to be worse than it has ever been before; it shews up badly in coffee that has not been thoroughly pruned and handled, and it is hard to say what is best to be done to neutralise its ravages which—just imagine!—are more serious now than those of the indefatigable borer. After pruning a tree badly affected with leaf disease, the hands become perfectly yellow with the rust, caused by the fungi, of the leaves. Coffee under charcoal shade, I notice, suffers severely from leaf disease; and this appears to me to be a good reason for the destruction of that shade tree. Coffee in good soil suffers very much less from leaf disease than that in bad; and, in this respect, estates with good soil, and which were originally heavy forest, have the advantage, and if every chance be given them in good cultivation, will doubtless keep leaf disease in check, yielding at the same time paying crops. Dusting the trees and ground every year after a thorough pruning with fresh slaked lime has shown most beneficial results, and, although it is not a cure for leaf disease, it has certainly checked it and allowed the trees to bear heavily, and will repay any one for the trouble and expense of application.

"WHAT is one man's food is another man's poison" is an adage, it is to be feared, which will scarcely solace coffee-planters for the information given us by the *Sydney Mail*, that 50 lb. weight of chicory seed has been distributed among cultivators in the south-eastern district of South Australia, with the view of extending the growth of that plant. It is impossible to take up a journal published in our coffee-producing colonies without reading testimony to the general belief that their industry is seriously affected by the extensive adulteration of coffee by chicory, and consequent demands that efforts should be made to induce the Home Government to check it. There may be other uses to which chicory is applicable, but there is no doubt that the soft flavour imparted by it to coffee makes the adulteration of the latter more favourably regarded than it otherwise would be, and therefore this effort in the direction of "new products" in South Australia will be certain to call forth complaint in Ceylon, and other coffee-growing Colonies, which even now have difficulty enough to sustain the competition to which they are exposed with countries where labour is almost compulsory, such as the Brazils and Java.

COFFEE LANDS IN MYSORE.

THE following proposed terms for the settlement of Coffee Lands to [illegible] as average assessment, are published in the Madras [illegible]

1. [illegible] on all assessable lands of [illegible]

[illegible]

2. Subject to the approval of the Government of India, permanent assessment at Rs. 1-8 per acre to those who may desire it, on the terms of the Madras Coffee Land Rules, but with a reservation of the Government claim to royalty on valuable mineral products, viz., metals and precious stones.

3. An assessment of eight annas per acre only for very poor lands, or for lands which have greatly deteriorated in their condition.

4. Grass lands in clearly defined compact blocks, to bear an assessment of four annas per acre if retained for pasture or growth of firewood.

5. Land newly granted to be held free for three years. To be charged with half assessment for the next two years, 4th and 5th, and to bear full assessment thereafter: Lands granted within the last five years to have the benefit of this rate, reckoning from the date of the grant.

6. Lands totally abandoned, or thrown out of cultivation owing to the ravages of the borer or other cause, may be taken up again on terms provided for new grants of land.

7. The assessment provided in Rule 1 to come into force at once in regard to old estates. But the settling officer may provide for the levy of half assessment only for any period not exceeding five years, when such consideration appears to be required in consequence either of the inferior productiveness of the estate as in the case of Native holding, or owing to portions of the estate remaining unplanted.

8. The area of grass land in an estate to be assessed under Rule 4 to be taken in the first instance on the estimate of the pattadar, subject to correction and levy of the proper assessment retrospectively upon survey.

9. Estates not exceeding 50 acres in extent must be relinquished wholly and not in part. In the case of estates exceeding fifty acres in extent, relinquishment will be permitted of a portion not less than one-half of the whole estate, or less than one hundred acres. Provided that the land relinquished shall form a compact block on the margin of an estate and divisible from it by a reasonably straight line of boundary, and provided further that the cost of re-surveying the land and of erecting the boundary marks required be borne by the applicant.

With regard to these terms the subjoined order has been issued by the Mysore Government :—

His Highness the Maharajah's Government has had under its consideration the terms proposed and sanctioned by the Government of India for the settlement of coffee lands in Mysore on an acreage assessment, and the correspondence connected therewith. His Highness the Maharajah entirely concurs in the views held by Sir James Gordon, that the interests of the State as well as of the planters are best consulted in according to them a permanent assessment, and he is pleased to accept and sanction the above terms inclusive of Rule 2 providing for a permanent assessment at Rs. 1-8 per acre to such of the planters as may at once offer for it. As it is understood that the above terms generally meet the wants and wishes of the planters, His Highness the Maharajah directs that the Survey Superintendent, in communication with the Deputy Commissioners of the respective districts, will at once take steps to carry into effect a settlement of the coffee lands on the above terms in the current year. The Survey Superintendent should, in communication with the Planters' Association and the Deputy Commissioners of Hassan and Kadur, submit a draft form of the title-deed to be issued to the planters. It will be seen that the Government right to a royalty on metals and precious stones, to sandals, and to an excise duty on areca-nuts is reserved, and that the lands will continue to pay the established local cesses. The halat duty on coffee as well as on cardamoms will, on the introduction of this settlement, be abolished. In regard to cardamoms on Government forest lands which are not held on cultivation pattas, arrangements should be made for their being given out on rent annually, or for longer terms. When the lower rates of assessment provided for temporarily by Rules 3 and 7 are fixed, planters will be allowed a permanent assessment at Rs. 1-8 per acre to take effect after the expiration of the temporary assessment, but their applications for the same should, as in other cases, be submitted at once. If Rule 9 requiring that estates not exceeding fifty acres in extent should be relinquished wholly and not in part is found to operate with hardships in the case of the smaller coffee estates held by native ryots, the Survey Superintendent should submit for consideration any modification of the Rule which may be required in the above cases.

COFFEE AT HOME.

THE figures presented by our London correspondent in his commercial report, which we recently published, claim careful consideration by reason of the great decline in the exports of coffee from London during the first eight months of the year, as compared with the corresponding period of 1880. It was shown that the export deliveries up to the 3rd of September amounted to no more that 25,227 tons; whilst in 8 months of the preceding year (which was itself by no means remarkable for a brisk continental trade) they were 36,040 tons, or a falling off of very nearly 11,000 tons. A closer examination of the items shows that the deficiency accrues chiefly in Ceylon and Brazil coffee, the proportion of the former being nearly 8,000 tons. At the same time, it must be borne in mind that on 3rd September the stock of coffee in London was less by 3,400 tons than the same date in 1880, whilst at the great continental entrepots there was a relative surplus of 34,000 tons.

It is quite clear, therefore, that continental dealers have this year resorted less to the London market than in last year, to the extent of about 30 per cent., either because they could do better elsewhere, or because there was not the same demand for the article. For a long time past the tendency has been towards the decentralisation of the coffee trade of London, and the promotion of more direct intercourse between producing countries and the European ports. This year especially the direct shipments from Rio and Santos to Havre, Antwerp, and Bordeaux have been on an exceptionally extensive scale. These remarks, however, do not apply to direct shipments of Ceylon coffee to continental ports, which during the current season have been about on a proportionate scale with the exports to the same places during last year. The argument, however, applies equally here so far as regards the tendency to direct communication between the country of production and that of consumption. No doubt our direct shipments of plantation coffee would [illegible] extensive than they are, were it not for the circumstance that [illegible] the finer growths of our mountain plantation crops must of [illegible] be shipped to London, and are therefore not procurable in the [illegible]

[illegible] Havre had on the 1st ult. reached the [illegible] high [illegible] at Antwerp 7,500 tons more than last year, and [illegible] at 2,790 tons. The truth is, no doubt, that heavy [illegible] have been made from Brazil to these ports; because the holders could not sell on the spot, and were bound to turn their goods into money, the consignees have been ready to sell at prices relatively lower than those ruling in London, and hence the inactivity of business there.

It is possible, too, that the consumption has fallen off in one at least of the chief coffee drinking countries of Europe. The emigration returns to the United States are of themselves sufficient to account for something in this matter. Last year more than 200,000 persons crossed the Atlantic from various European States not including the United Kingdom, and this year it is reckoned that the number will not fall far short of 300,000. By far the larger proportion come from Germany, but there is a good sprinkling of Norwegians, Swedes, and Italians, and it may safely be said that they are all coffee drinkers. Moreover, the enormous increase of emigration from Europe lately is itself a sign of poverty and depression amongst the labouring classes who form the bulk of the emigrants, and as a matter of course those who remain also suffer, though they do not adopt the same remedy, and it is reasonable to suppose that amongst the household economies enforced upon them is the restricted consumption of coffee; so far as the emigrants are concerned, they only transfer their consuming power to another sphere, where they are doubtless soon in a better position to gratify them, and hence the hitherto steady increase of consumption of coffee in the United States.—*Ceylon Times.*

CINCHONA.

THE Cinchona Succirubra is now being extensively cultivated in Coorg, the fine prices it realizes, (3*s*. 4*d*. to 3*s*. 5*d*. per lb.) and its suitableness as a shade for coffee, have rapidly brought it into notice.

A SINGLE cinchona tree, about eight years old, in Ceylon, grown at an elevation of 5,000 feet, was rooted up the other day and yielded 96 pounds of wet, and 32 pounds of dry bark. If this tree were a Succirubra, it returned no less than £4 of crop, making an acre of plantation of this variety worth £4,800.

AN idea of the progress that has been made in shade cultivation in South Coorg may be ascertained by the fact, that several planters find that their planted shade has grown so thick that they are obliged to thin it out to enable the coffee trees to crop properly.

A SALE of Cinchona Ledger seed took place on the 21st inst., at the office of Mr. C. E. H. Symons. There were forty-five boxes of seed put up, each box containing two grammes or thirty-one grains English weight. The first sales were made at Rs 50 the box, after which the price of Rs. 60 was realised, and finally one small box, sold as containing a quarter of a gramme or not quite four grains, realised as much as Rs. 11. According to these figures the first boxes realised at the rate of Rs. 774 the ounce, the second at the rate of Rs. 929, and the third small lot at the rate of Rs. 1,361 the ounce, or equal to Rs. 21,791 per pound.

THE manufacture of cinchona febrifuge is steadily on the increase, the demand becoming larger year by year as the article becomes known. The quantities manufactured each year have been as follow :—

			lbs.	*oz.*
1874-75	...	...	48	10
1875-76	...	...	1,940	6
1876-77	...	...	3,750	12
1877-78	...	...	5,162	0
1878-79	...	...	7,007	6
1879-80	...	...	9,434	13
1880-81	...	...	9,296	0
	Total	...	36,639	9

The cost of making this valuable medicine was as follows :—

354,480 lbs. bark ...	Rs.	58,136	11	6
Cost of manufacturing, &c.	„	27,784	10	9
Total	Rs.	85,921	6	3

Cost per lb of febrifuge made—

Bark	Rs.	6	4	0·76
Manufacturing	„	2	15	9·865
Total	Rs.	9	3	10·625

This is all very well from a Government point of view, but it is not a fair estimate of the cost of producing a pound of febrifuge, and, to the extent of this error, it so far militates against private enterprise engaging in the business. Suppose a joint stock company were to commence the manufacture of this febrifuge, they would have to purchase their raw material in the open market, and so far from obtaining the bark at 2as. 6·4147 pies per lb, the amount debited in these accounts as the value of the bark, they would have to pay about Rs. 1-4 per lb. It takes 38·13lb of bark to make a lb. of febrifuge; consequently the cost would be something like this :—

38·13 lb bark Rs. 1-4 =	Rs.	47	10	7
Manufacturing charge, say ...	„	2	15	11
Total	Rs.	50	10	6

It would thus be manifestly impossible to place it in the market at 20 rupees per lb. The quantities sold during the last two years were :

1879-80	... ...	8,164 lbs.
1880-81	... ...	8,654
Increase	...	490 lbs.

equal to an increment of 6 per cent. Besides the febrifuge now in use, Mr. Gammie, the accomplished and successful Superintendent of the gardens and factory, has "succeeded in turning out a crystalline prepared of the febrifuge which, being free from the amorphous alkaloid, may prove a pleasanter medicine than the febrifuge in its present form. Mr. Gammie's crystalline febrifuge is a very pretty proparation, being nearly as white as quinine itself. It is now under trial in various Government hospitals, and if it is reported well of, arrangements can be made for its production on a large scale." "Mr. Gammie has continued to direct his attention to the economical manufacture of sulphate of quinine. Decided progress has been made in this matter since last year, but further experiments will be necessary before I," says Dr. King, "can advantageously submit a full report on the results." The plantation, near Darjeeling, whereon these experiments are being carried on, is itself a great success. The number of plants now growing is as follows :—

Cinchona Succirubra	...	4,034,535
Cinchona Calisaya	...	412,695
New unnamed variety	...	199,898
Other kinds	...	30,592
	Total	4,677,720

An effort is being made to extend the cultivation of the *Ledgeriana* variety of the *Calisaya*, as it has been found to give the best result. A small parcel of *Calisaya* bark, of too low a quality to be of service at the factory, was sent to London for sale in open market, and this invoice, which weighed 12,519lbs., sold at prices ranging from 2*s*. 9*d*. to 7*s*. 6*d*. per lb., the average price realised being 4*s*. 6½*d*. With this were sent 625lbs. of *Ledgeriana* bark (the first which has gone to London from India) to test the market, and this small sample realised 10*s*. 10*d*. per lb., which must be considered very satisfactory.

CINCHONA CULTIVATION IN BENGAL.

THE annual report for 1880-81, of the Superintendent of the Royal Botanic Garden, Calcutta, and the Government Cinchona Plantation in Bengal, is one that will interest the planter, the physician and the public. To the former, perhaps, the most interesting fact is the sale by public auction in a parcel of 625lbs. of Ledgeriana bark, at the rate of 1[illegible] 1[illegible]*d*. per lb. proving that the cultivation of this variety in India justified the high opinion that early analyses indicated ; and that the valuable property of yielding a high percentage of crystallizable sulphate of quinine may be relied on as a permanent peculiarity of the variety. That this opinion is held by the officer in charge of the plantations is proved by the planting out of over 100,000 plants of this variety of Calisaya in the Mungpoo and Sailong reserves, and the formation of large nurseries to keep up the supply for future years. On the other hand, the extension of area under the Succirubra variety, has not been proceeded with, a forest of four millions of these trees being considered ample to provide "druggist's" bark for preparations, decoctions, and tinctures, and also the Government febrifuge which may be styled the mainspring of the enterprise. The only attempt at introducing a new variety, that yielding the Carthagena, or Columbian bark, has also apparently been fairly started ; for although there were only four plants in 1880, there were in July sixty rooted, and ninety partially rooted, cuttings, combating with success the attack of the "turnip" pest which has attempted their destruction. Cinchona planters will note with interest that 75 acres of Succirubra reported at eleven years old, gave a yield of bark averaging 20lbs. per tree, which is considered poor ; that a southern aspect has been found most suitable for Ledgeriana and that the Java plan of shaving the bark of living trees to the height of eight to ten feet from the ground, has been a success, the bark renewing perfectly. But while we have successfully followed the lead of the Dutch planters, headed by Moens in Java in the method of gathering bark, another of their experiments has not been attended on these plantations with success. While the Ledgeriana is valuable from its peculiarity of yeilding an alkaloid rich in quinine, it suffers from a delicacy of constitution and a timid habit of growth. On the other hand, the Succirubra is remarkable for its vigor, and adaptability to widely varying soils and climates. By grafting the richer variety on the poorer, it is hoped that the more valuable characteristics of both may be combined, and a bark containing alkaloids, yielding 10 per cent. or even 15 per cent. of quinine, be grown with the freedom that Succirubra yields in its present one to two per cent. condition. So far failure to achieve this in Bengal is reported, though we have seen the the plan successfully carried out by two methods in the Wynaad, so there is reason to hope that the further trials which are to be made may meet with success.

In the several essential points the Government in growing Cinchona for the manufacture of its alkaloids into medicinal products, has achieved a marked success. The total out-turn of the febrifuge Factory during the year was 9,296lbs., obtained at an average cost of Rs. 9-3-10 per pound. The sales to the public are steadily growing, and this year amounted to 3,150 lbs., showing an appreciation of its value that has extended beyond official circles ; while to medical depots no less than [illegible]lbs. was supplied.

"The actual profit exhibited on the year's working was Rs. 83,290, equal to 8 per cent. on the capital of the plantation, while the value of the stock in hand at cost price was Rs. 94,921. This, however, does not represent the whole of the gain of the year. The price of quinine was very high, and the cost of 5,550 lb., which would have been used by Government had the febrifuge not been available, would have been at the lowest estimate Rs. 5,50,000. The cost of the febrifuge used was only Rs 90,880. There was thus a clear saving of Rs. 4½ lakhs. The saving effected by similar substitutions of febrifuge for quinine in previous years amounted to 11¼ lakhs. The total saving therefore has already amounted to more than 16 lakhs of rupees." Considering that but for the labours of Mr. Clement Markham, acting on behalf of Government, the growth of cinchona in India might be still untried these may be regarded as magnificent results. At the same time if appears that as the object of the Government is not to make a profit, but to obtain an efficient antidote to fever at the lowest possible cost, the question of lowering the price of the febrifuge might be seriously considered. The introduction of quinine producing plants, and their successful propagation will always be a feather in the cap of the Government of India, but while taking all due care of those who are too poor to take care of themselves, they must be careful not to check private enterprise. A true middle course is not difficult of attainment, and we would suggest that as their aim is primarily cheap febrifuge, such could be attained by purchasing as well as growing barks and erecting suitable manufactories at convenient centres. The report speaks of Mr. Gammie the executive officer of the Mungpore factory, discovering processes by which the various preparations of Cinchona bark are cheapened, and it would be a help to many planters if they could sell indifferent barks in India. It is from such barks that the febrifuge is mainly manufactured so the Government would gain in obtaining quantities that might permit of a sensible reduction in price, and lead to an increased demand.—*Madras Mail.*

CINCHONA CULTIVATION IN JAMAICA.

THE following appeared in the Kingston (Jamaica) *Gleaner* and *Tri-weekly Gleaner* of the 27th August, 1881 :—

We publish to-day the terms upon which the Government of this Island, being desirous of encouraging the cultivation of Cinchona, offers to make grants of public lands to persons who will embark in the enterprise. The situation of the land is not mentioned, but we presume the extensive unopened tracts of forest on the higher Blue Mountain slopes are referred to. The Government has already encouraged, under favorable concessions, the cultivation of cinchona by private enterprise thereabouts, and is now, we are glad to believe, seeking to establish the industry systematically. The land we speak of lies at elevations of from 4,000 to 6,500 feet ; is without roads but of fine quality ; is distant from Kingston two-score miles, but possesses a climate delightful alike to those who dread the cold of a northern winter and those who dread the heat of tropical high noon.

To anyone who thinks seriously of investing his capital in cinchona cultivation in Jamaica, but fears to venture, we would point out that he will not be alone in the undertaking. We could name at this moment several gentlemen, including His Excellency the Governor, who have devoted land and capital to it. In his last Report, Mr. D. Morris stated that large numbers of plants had seen put out at Whitfield Hall, Radnor, and Clydesdale. To this list, the names of many well known high plantations between St Catherine's Peak on the west, and Blue Mountain on the east, might be added, while the cultivation of cinchona adapted to lower elevations is being prosecuted with vigour in Manchester. The demand for seeds and plants increases daily, and can hardly be met. This new industry brings into productiveness regions which in many cases were unsuited for coffee or provisions, and which were a burden on the owner. We regard this departure as creditable not only to the Government, but to the planters who have been so often, so foolishly, and so freely accused of indifference to their own best interests, and to opportunities of unfamiliar profit.

Estimating the gain which may accrue from new enterprises is always a delicate affair. In the present case we will give the statements of authorities on the subject in preference to opinions of our own, merely pointing out that many of our shrewd and experienced planters have satisfied themselves as to the profit derivable from cinchona, and have given evidence of the faith that is in them. In his valuable report, to which we have already referred, Mr. Morris describes how he found a little patch of *cinchona officinalis* which had long been deserted on Whitefield Hall Estate, and which was found hardy and thriving He says :

"As indicating the value of cinchona planting in the Blue Mountains—taking these 379 trees which occupied an area of less than 120 square yards—it was estimated that if they yielded on the average one pound of dry bark per tree (young trees at the Government Plantations yielded 1½ pounds per tree) each tree would be worth at least 5*s*. ; this would give £94 15*s*. as the value of 379 trees on an area of 120 square yards, one-fortieth of an acre. Under ordinary conditions it would not, however be advisable to plant the trees so closely as this, but the value of an acre of land planted with trees even at one-half the above rate would amount to more than £890. Large as this sum may seem, it appears that with the precious Ledgeriana Bark, grown by the Dutch in Java, (a few plants of which have just been introduced to Jamaica) the yield per acre, as quoted by Mr. J. E. Howard, F. R. S, is estimated, from actual sales, at £2,000 per acre."

We will take, in addition to the above, the statement made by Mr. Clements Markham in his interesting and important monograph on "Peruvian Bark." In his chapter on "Financial Results," he says:—

"The results of the sales of bark from the Government cinchona plantations on the Nilgiri Hills, in India, is that a sum of £173,046 has been realised. The total cost of the whole enterprise from the commencement, including interest, was £129,628 in 1876. By the year 1879, allowing for charges during intervening years, the sum to be debited against the enterprise was only £38,942. In 1880, the whole capital account had been paid off with intreest, and the plantations began to yield a clear annual profit. It is therefore true of the Cinchona enterprise that as a mere commercial speculation, it has paid off the whole outlay, including introduction of the plants, cultivation, and interest ; and has become a complete financial success."

Mr. Markham also gives figures to show how private enterprise in India and Ceylon is reaping the same reward. For his remarks on this point, we must refer our readers to his work. It is shown that while the Government of India will in future have as much demand as it can meet, in supplying cinchona febrifuge for the milions of India, the planters of Ceylon and India, as well as of Java, find a ready and profitable demand for their bark in Europe. At the same time a vast market for the bark is being found in China, where until now opium has been the cheapest drug as a cure and preventive of fever, and where from 30 to 40 per cent. of the population use it, to their own ruin and to England's disgrace.

The prices obtained for Jamaica bark should stimulate to activity in planting Cinchona. Mr. Markham, in his sketch of Cinchona cultivation in Jamaica, says that *C. officinalis* does not thrive so well in this Island, but he speaks favorably of *C. succirubra* and *C. calisaya*. But the latest results furnished by sales of Jamaica "grey" barks, are proof that *officinalis* grown here commands better prices than that of Ceylon; and last week we had an opportunity of seeing how, as Mr. Morris describes, the *officinalis* spreads in self-sown forest patches at the highest elevations, thus exhibiting great fitness for the soil and situation. The Island has now, therefore, at least three kinds of cinchona well established, *officinalis succirubra*, and a good variety, called *calisaya*, but supposed to be a hybrid between the other two. Moreover, the *ledgeriana*, a variety of *calisaya*, introduced by Mr. Morris, is now growing well, as a plant, and seed of it has already been imported. Of this *ledgeriana*, which Mr Morris says fetches 17s. per lb at Amsterdam, Mr. Markham writes: "These plants yield an extraordinarily large quantity of quinine, as much as 9,97 per cent. In this respect they are unequalled." With regard to the species known as *succirubra*, and yielding the "red" bark of commerce, a variety which Mr. Morris recommends as being peculiarly suited to so much of our land from 2,000 feet upwards, Mr. Markham writes that it yields a larger percentage of febrifuge alkaloid than any other. As time rolls by, other varieties again may be found to naturalise themselves easily, "the Blue Mountains of Jamaica * * * being about the same distance from the equator on the North side (18o N.) as the calisaya forests are to the south."

As the Government now offers land for cinchona, it is also ready to supply the seeds and plants. Seeds of the *officinalis*, for cultivation at elevations above 4,000 feet, are supplied at 5s. an ounce; of *succirubra*, at elevations between 2,500 and 4,000, at 3s. An ounce is sufficient to produce 20,000 seedlings, which will plant five acres. Boxes of seedlings may be had at a guinea per box, and plants are obtainable at from 40s. to 60s. per 1,000.

We hope to witness an early extension of cinchona cultivation by men who have capital and can await the first yield in the fourth or fifth year. The opportunity now offered is excellent. It is possible that a market for the Jamaica bark will be found some day in the U.S.A., which consumes vast quantities of quinine, but for the present, England takes all that can be shipped, and at remunerative prices. The time cannot be far off when the masses of Jamaica will be provided by government with a cheap, effective febrifuge, now so greatly needed. And leaving out of question the commercial and social advantages resulting from cinchona, it may be fairly claimed that this tree, which once inspired the prose of Madame de Genlis, and the verse of Le Fontaine, will, with its graceful stem, shining leaves and clustering flowers, be an additional adornment to the far famed but neglected mountains of Jamaica. [We are sorry we cannot find room for the rules referred to. They are like other waste-land rules we wot of, and will not, we think, entice investors.—ED., *I. A.*]

SERICULTURE.

SILK culture is exciting considerable interest in the south and west of the United States, cocoons and eggs being now raised in Louisiana, Georgia, California, Utah, Pennsylvania, North Carolina and Missouri. The cocoons are worth in the market \$2 a pound, and the eggs from \$3 to \$4 an ounce. The climate and soil of California are especially adapted to silk culture, and there are in that State a number of Europeans expert in the business. The *San Francisco Alta*, in a recent article on the subject, says that some years ago cocooneries existed in various counties, but they were not profitable, and all went out of operation, the trouble being the expense at production. At the present time, another combined effort is being made to introduce the industry.

THE Agricultural Bureau at Washington has received information that a new variety of silk-worm has been discovered accidentally in Nevada. Naturalists pronounce the worms *Bombyx quercicus*. This is a silk-worm largely used in China. It makes several broods in a year, and its silk has peculiar qualities. The fibre is stronger. All other silk-worms, in emerging from the cocoon, cut a hole for exit, which, by breaking the continuity of the thread in unwinding, renders it of little value. The *Bombyx quercicus* pushes aside the threads instead of cutting them, and the cocoon is as valuable as others reserved in ordinary kinds for spinning by killing the contained worm. This new silk-worm is hardier than the old; it is raised in the open air, needing neither care nor shelter.

A DESPATCH from Italy, says an French paper received yesterday by a silk-firm in our town says that hatchings (of silk-worms' eggs) have on the whole, been satisfactory, and that, so far, all goes well in this respect The silk markets of Lyons and London are quiet, and prices are low. One need not be astonished that, under such conditions, transactions should be limited in Yokohama, where stocks are small, especially in good staples.

AMONG the striking signs of progress now visible in Japan, not the least important is the attention they are giving to their silk trade. They now propose to start a silk association or guild in Yokohama, with a capital of 30 million yen (£6,000,000). The idea is to perform an operation analogous to bulking tea. The silk of all members will be received by the guild, and be carefully graded according to quality advances will be made to manufacturers, and all silk passed through the guild will go to Europe, not as the make of any individual concern, but as belonging to, and guaranteed by, the guild. To a large extent this will do away with opportunities for private speculation of silk makers, but in the long run it should lead to better prices being obtained for silk passing through the guild's hands. Such would acquire a certain value, as the incentive to cheating would largely be eliminated Such a guild in Calcutta in connection with tea could not fail, to succeed, if only the feeling of jealousy connected with valuing were got over. An entirely disinterested and trustworthy valuator might be appointed to receive and put a price on all lots received; advances could be made on each lot, or payment in full made at the rate of one anna under the valuation. The tea would then be bulked in lots of a thousand chests or so, carefully re-dried, and packed for London, not as the individual brand of any garden, but as the property of the guild. At the close of the year, all profits could be divided *pro rata* among the members. By this means the teas of the guild would speedily acquire a name for almost absolute uniformity of quality, and members could not fail to benefit by the proceeding.

SILK ADULTERATIONS.

IT has been proved by numerous experiments that all pure silk burned in a gas flame yields in ashes two-fifths of the original weight, and that all weighted silks, when burned in a gas flame, weigh less than two-fifths in proportion as they are weighted, and where there is much iron, "the chief adulterant," the colour of the ash is a red brown. From pure silk the ash is always black, and the silk while burning seems to melt and run together, while the weighted silk keeps its form, shrinking equally from all parts It is not necessary to burn any pure silk "unless comparisons are desirable," if you take the fact as established that the resulting ash is two-fifths of the original weight, and all silk not coming up to that standard is proportionately weighted.

The theory is pure silk leaves a residue of two-fifths when burned to ash, and the weighted leaving very little ash from anything but the silk it contains, the adulterants being principally converted into vapour and gas, pass off, leaving no perceptible weight of residue. The best method of burning the silk for testing is to lay it on a piece of wire gauze and let the gas flame pass through.

Scale.

20	parts silk	yielding	8	in ashes is	pure	silk.
20	"	"	7	"	$\frac{7}{8}$	"
20	"	"	6	"	$\frac{3}{4}$	"
20	"	"	5	"	$\frac{5}{8}$	"
20	"	"	4	"	$\frac{1}{2}$	"
20	"	"	3	"	$\frac{3}{8}$	"
20	"	"	2	"	$\frac{1}{4}$	"
20	"	"	1	"	$\frac{1}{8}$	"

A very good idea of the purity of silk is shown by comparison: taking a piece of ribbon—any pure colour white, blue, pink, gold, or any bright colour—"one inch or two is sufficient," weigh carefully; then weigh exactly the same weight of silk to be tested and as much as it falls short in measurement with the pure silk it is weighted Endeavour when testing as above to get a piece of ribbon the same substance as that to be tested.

When it is considered that the weighting is a very expensive process, and that the adulterant weight does not in proportion add to the bulk, and that the strength, durability, softness, and lustre are greatly impaired, [illegible] that the [illegible] is persisted in; but it being so, and the consumers must necessarily pay the expense of the adulteration, it is for them to understand how to protect themselves

There are many black silks that are valued by weight, manufacturers and dealers agreeing as to the dyed weight; such is what is termed French twist often returned by the dyer three pounds for one. This silk twist is made from waste, and as it is cut up and carded there is a great amount of fine fibre on the surface, causing a dull and woolly appearance. In the process of dyeing the silk is rotted by the many baths of nitrate of iron and other chemicals; the fibre on the surface becoming very tender is beaten off leaving a smooth hard twisted thread; but the processes are so detrimental to the strength, its use is confined to cutting up into fringes, but it soon shows its components, in becoming dull and cottony.

This French twist costs in the gray about four dollars per pound, and the dyeing heavy weight two dollars and fifty cents, so when finished, there is returned three pounds for six dollars and fifty cents, or two dollars and sixteen and three-quarter cents per pound. If dyed in the regular way, sixteen ounces would return twenty and cost fifty cents for dyeing. So in that way the good silk would cost four dollars and fifty cents for twenty ounces, or three dollars and sixty cents for one pound, against two dollars and sixteen and three-quarter cents for the heavy weighted. Let it be understood that the same number of yards and the same amount of good silk is in twenty ounces, costing four dollars and fifty cents, as in the forty-eight ounces heavy weighted, costing six dollars and fifty cents, and that the four fifty silk is clean and strong while the six fifty is dirty and rotten. So the advantage is hard to be understood, and perhaps is only in the fact there are yet very many who can only understand a pound is a pound and a yard is a yard and silk is silk.—*American Paper.*

TOBACCO.

IT was lately stated that the tobacco and cigar trade was steadily on the increase, and that large supplies were being sent from Madras to Great Britain and other places. It would appear from the return recently published that 4,399lbs. of tobacco and cigars, of which 2,703lbs. were shipped to Rangoon and 450lbs. to Yokohama, formed the export trade of Madras, last month in tobacco.

We publish the following papers at this Office:—

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily publication, but as a guarantee good faith. We shall take no notice of anonymous letters.

THE DIVI-DIVI PLANT.

(*To the Editor of the Madras Times.*)

SIR,—I notice in your paper that the Divi-Divi plant cultivation appears to be the question of the day, and as your readers may be glad to get some particulars regarding it, I send you a few remarks resulting from my own experience of the same. To the inquirer of the Tamil or Telugu word for Divi-divi, I will reply that it is difficult to satisfy him, as the Divi-divi or Libi-dibi (botanically Coesalpinia Corearia) is an American tree introduced in India by Doctor Wallich in or about 1813; its foreign origin is, perhaps, the cause of no Tamil or Telugu designation appearing for the same in the botanical works as *Flora Indica*, into which I have searched. The native gardeners call it in Tamil *Cona Vilen*, on account probably of the form of the pods, which are turned as the letter S. There does not appear to be any designation in Telugu.

The Divi-divi pods are employed for tanning purposes, as they contain 50 per cent. of pure tanin. I have been told that in Bangalore there is a large plantation of this tree, and that its pods are largely used for giving the skins that superior smoothness remarkable in the Madras and Bangalore skins.

I have also used Divi-divi in dyeing, and I have employed a solution of acetate of iron after the bath in Divi-divi tincture. The ink used in most of the Government offices in Fort St. George is made with this plant.

The cultivation of this elegant shrub is very easy. The seeds should be sown in March, and the young plants can be removed from the nursery during the following rainy season ; they require some watering till they have attained the height of three feet, after which no more care is necessary. This plant grows luxuriantly in a clayish, calcareous soil, but very slowly in red soil, as I have observed at the Red Hills near Madras I think the difference in the growth in the two soils results from the clayish soil retaining moisture for a very long time in the summer, while in the latter the young plant is exhausted by the strong dry winds blowing on them. But I think still possible to cultivate this shrub in red soil with some success, by adding dry mud from tanks to the soil before replanting the young trees from the nursery. Cow-dung ashes will prove useful round the plant The great difficulty to contend with, however, in such soil is the want of water The cultivation I have made for the last few years is quite a success, and I have made experiments in both soils, clayey as well as red. I shall feel obliged if any of your readers will give me some information regarding the market current price of this dye in London or elsewhere. I think that the high rate of freight from India to Europe will not allow a margin of profit in the shipment of Divi-divi husks.

SEARCHER.

A BUBBLE-MAKING PLANT.

(*To the Editor of the Madras Mail.*)

SIR,—Among the numerous wild plants indigenous to Southern India, allow me to introduce one to the notice of your numerous readers. It is to be found in almost every hedge-row about the outskirts

of Madras and Bangalore, and somewhat resembles the castor-oil shrub, the leaves being nearly of the same size and shape, but of a lighter green hue. The Tamil name of it is "katamoney," by which it is well known among the natives. The fruit which grows on it in clusters is above the size of a damson, and an inferior kind of lamp oil is sometimes extracted from the seeds. The most singular part of the plant is a limpid juice which exudes from the leaf stalks when plucked, and which appears to possess highly saponaceous properties. This the native children have not been slow to appreciate, having turned it to account in the manufacture of bubbles, which are vastly superior to those made from soap and water, inasmuch as they are more tenacious, and their specific gravity appears to be considerably less. The bubbles moreover do not suddenly burst and instantaneously vanish like the ephemeral soap bubbles, but remain floating in the air for some seconds, gradually lose their irridescent hues, and assuming a milky or opalescent tint, slowly collapse and descend to the ground like particles of down. For the manufacture of these bubbles no pipe is necessary ; a bit of horsehair, cocoanut fibre, or the midrib of a large leaf bent in the form of a small loop being the only appliance needed. The loop is merely dipped into a cup containing the fluid, and when blown a score or more bubbles are formed and fly off at every puff, so that in a few moments the air is filled with hundreds of radiant little globes the effect of which is most pleasing, especially to the little folk. The juice is also largely used by the natives as a remedy for sore mouths ; and I think it would also answer as a detergent or dentifrice, as a few drops sprinkled on a wet tooth-brush and applied in the usual manner produce a foam in the mouth very similar to that caused by "floriline." The natives assure me that it is quite innocuous. The plant is a very hardy one, and will grow on almost any soil in any part of India.

OLD MADRASSEE.

AGRICULTURAL EDUCATION.

(To the Editor of the Madras Mail.)

SIR,—You are aware that in February last, a memorial was presented to the Madras Government, by the former and present students of the Madras Agricultural College, praying for an honorary degree to raise their social status. The Government, appreciating the value of agricultural education in a country like India, whose riches lie buried in the soil, and deeming it unnecessary to confer honorary degrees, forwarded the memorial to the University of Madras, for consideration. Another petition was prepared by such of the students of the Agricultural College as have passed the Matriculation, and was forwarded, in June last, to the Senate, in which they prayed for University degrees on certain grounds. The Senate seems to differ from the Government on the value of agricultural education. It is rumoured that the Senate is not willing to grant any University degrees to the students, on the ground that they are not F.A's. Students join the Agricultural College at Saidapet, not only from different parts of India, but also from the Colonies, as this is the only one in the East. Would it not be better for the graduates of the Agricultural College to return to their distant homes, with a hood and a gown, than to return just as they started three years ago from their beloved homes, to receive agricultural education at Saidapet ? If the Bombay Agricultural College had worked as efficiently as the one at Saidapet, I am sure that the benign University of that Presidency would have ere long conferred University degrees (*vide* Sir Richard Temple's Minutes on Agricultural Education at Bombay) on the graduates of that College. My humble opinion is, as the Madras University is not to confer any degree without examining the candidates, that Matriculates ought to be allowed to compete, and that F. A. examinations are superfluous for agricultural degrees. It remains to be seen what reply the memorialists will receive from the Government if the University decline to grant degrees to Matriculates

CHINNAPPEN.

THE BIJNOUR AGRICULTURAL SOCIETY.

AIMS OF THE SOCIETY.

[*Communicated.*]

SUMMARY.

1. THAT the attention of the cultivating community be drawn to the sundry kinds of manure that lie, so to speak, at their very doorsteps, but of the value of which they have little or no conception.

2. That ploughs similar to the kaisar plough of Cawnpore be manufactured at Bijnour, and sold at cost price as well as let out on hire to secure their general adoption, also that steps should be taken to extend the use of—(1) Beheea mills, a good lot of which should be purchased and given out on hire ; (2) winnowing machines ; and (3) water-lifts.

3. That the Society manage to supply the agricultural classes with good seed of all crops wherever it could be procurable.

4. That measures should be devised to improve the local breed of cattle generally, and that the establishment of a cattle-breeding farm in a carefully-selected situation near the jungle should form a part of such schemes. That to obtain a better supply of fodder, efforts should be directed to promote grass reserves, cultivate root-crops, retain oil cakes, improve indigenous kinds of fodder plants, and introduce new ones, such as sorgho, lucerne, reana, guinea grass, and the like ; and further that medicines for the several cattle diseases be made accessible to the agricultural classes with a view to their prevention by means of a cattle-disease medicine depôt at Bijnour.

5. In connection with the subject of irrigation, Government be induced to extend the system of State wells, as it seems to be the best means of ameliorating the condition of the cultivating population.

The latter may be also persuaded to make artificial tanks and reservoirs.

6. And lastly, that an agricultural show should be held at Bijnour this year, being the most efficient means of creating interest in agricultural matters and enlisting the active sympathy of zemindars and cultivators.

The Indian Agriculturist.

CALCUTTA, DECEMBER 1, 1881.

OUR MARITIME TRADE.

MR. J. E. O'CONOR has issued another of his useful and carefully compiled reviews of the maritime trade of British India with other countries. It is for the year 1880-81. We have already noticed totals, and shall now deal with details. To commence with imports, the receipts of quinine have fallen from 7,409lbs. in 1879-80 to 3,964lbs. in 1880-81, a decrease of 3,445lbs., or 46 per cent. Mr. O'Conor thinks that the "great epidemic fever, which swept over Northern India in the autumn of the former year," must have increased the demand for quinine. Doubtless, but the large quantity of cinchona febrifuge now used instead of quinine, may have something to do with the decline in 1880-81. The trade in imported malt liquors does not expand, and is now practically the same as it was four years ago. This is not due to a decreased consumption per head, but to the large quantities now being made and consumed in India. In 1880, no less than 1,974,578 gallons were made in India, of which Government purchased 1,298,773 for the troops, leaving 675,805 for general consumption. Machinery and mill-work increased from Rs. 61,68,327 to Rs. 76,98,437, and this is one of the most promising signs noticed in the report. The consumption of kerosine oil has increased in an astonishing manner, and has now reached 9,692,269 gallons per annum. We learn that the refining of the Borongo Island oil, near Akyab, has now been successfully accomplished, and we may soon expect to find it competing with the American oil. Paper and pasteboard figure at Rs. 48,60,076, which, at an average of four annas per pound, represents 8,700 tons, a very large proportion of which ought to be made in the country. Raw silk, to the extent of 2,511,802lbs., was imported, and that into a country like India which might supply the would with silk. Mr. O'Conor looks hopefully on the soap industry which, he thinks, will prevent importations from materially increasing in the future. Sugar is still imported into Bombay from Mauritius and China ; and surely this should be unnecessary, if the indigenous industry were enterprisingly pushed. The quantity so imported last year was 49,118 tons. Perhaps the most anomalous import we have is tea. It is hardly conceivable that, while Indian tea continues to advance in public estimation at home, we

should not only use China tea in India, but that in increasing quantities, as the following statement will show :—

		lbs.
1876 77	... ...	1,755,300
1877-78	... ...	2,323,033
1878-79	... ...	1,822,345
1879-80	... ...	2,534,518
1880-81	... ...	3,322,407

Mr. O'Conor gives a reason for this, and it is one which we have already asked planters to remedy. It is that Indian tea is sold in too large packets to be easily obtainable by the general public. As a rule the smallest quantity one can buy is one pound, whereas an ounce of China tea can be purchased. If only India tea-planters, or vendors of the article would place Indian tea on an equal footing with China, a vast business would be done. If it were sold in ounce, or two-ounce packets, the entire make of our lower grades would easily be disposed of locally, thus securing a much better and convenient market for all the lower class teas made, and to that extent relieving the London stock of the article, and enhancing the value of tea in the market, while sensibly increasing the average quality placed on it with the obvious result of improving the reputation which Indian tea is already fast acquiring. Under these conditions nothing under a good Souchong, need be exported to London.

The impetus recently given to cigar-making in India is beginning to have its natural effect; the importation of foreign cigars fell from 88,082lbs. in the preceding year, to 65,782lbs. in the year under notice, a decrease of 25 per cent.

Our export trade shows signs of elasticity, and this is of great importance, as it cannot fail to indicate an improving position. Our cotton industry is showing steady progress. The following are the exports in rupees of twist and cloth of Indian manufacture :—

		Twist.	*Cloth.*	*Total.*
1876 77	...	36,73,028	44,50,794	81,23,822
1877-78	...	68,20,585	46 06,738	1,14,27,323
1878-79	...	88,64,812	51,14,980	1 39 79,792
1879-80	...	1,10,92,336	51,25,132	1,62,17,468
1880-81	...	1,28 25 761	62,65,579	1,90,91,34 3

There can be no doubt that this reveals a prosperous state of the industry. Besides this, who can estimate the quantity of Indian manufactured cotton consumed in India ?

The fluctuating nature of the Indian wheat trade is clearly shown in the following statement :—

1876-77	...	5,583,336	cwts.
1877-78	...	6,340,150	"
1878-79	...	1,044,709	"
1879-80	...	2,195,550	"
1880-81	...	7,444,375	"

and during the first four months of the present year (1881-82), the exports have been at the rate of one and-a-quarter million cwt. per month. As we have frequently said before, we think the railway companies are not sufficiently awake to their own interest in connection with this vast trade. As soon as a steady increase in forwarding traffic shows itself, rates are immediately raised. In this respect the Great Indian Peninsular Railway has been the worst offender, and is experiencing the just reward of such folly in a decreased carrying traffic. Of the 7½ million cwts. exported, 4,802,233 or 64½ per cent. went to England. In oils, we export largely, although not nearly so extensively as we might. The value of the exports, which principally consisted of castor and cocoanut oils, was 37¾, 37, 53¾, 57 and 58 lakhs of rupees for the five years, 1876-77 to 1880-81, respectively. At the same time, we must not overlook the fact that, while the value of oils exported last year was only Rs. 53,11,394, oil-seeds to the value of Rs. 6,34,52,089 were exported. Now, as this seed was purchased for the purpose of having the oil extracted, there is no reason, except want of business enterprise, why we should not make a great deal more oil than we do. The exports of Indian silk are sensibly declining, and this is much to be deplored, as the silk industry is one peculiarly adapted to the habits and aptitudes of the people of this country. We suspect the poverty of the people has a good deal to do with this. The exports of Indian sugar have fallen from Rs. 92,51,961 in 1876-77 to Rs. 31,17,508 in 1880-81, a decrease of 66 per cent. in four years. Attention is drawn to the advisability of encouraging other markets than London for the tea trade, and Mr. O'Conor, who speaks with authority, deprecates the returning tendency to flood the London market, and neglect that of Australia, simply because prices have temporarily risen in the former place. This, he rightly considers, suicidal, and he points out "that every pound of tea diverted from the London market, must tend to raise prices there, and keep them at a profitable level." "It may be hoped," he adds, that the temporary elevation of prices in England will not divert the attention of planters from Australia and the United States, and that now that these markets have been opened to them, they will be sagacious enough to keep them open by an uninterrupted and copious supply of tea." This is very much to the point, and we trust that the tea exporters of India will not permit the exports to London to increase, in like ratio with the increased production of our gardens, but will perseveringly find markets elsewhere for the surplus. By following this policy for a few years, the prices in London will be certain to keep up, and Indian tea will assume the position, relatively to China, to which its superior qualities entitle it. Tobacco, too, is a hopeful export. There are few countries in the world better adapted for the prosecution of this industry than India. So far as its growth is concerned, India need fear no rival. The value of the export for the past five years have been as follows :—

		Rupees.
1876-77	... ...	8,91,398
1877-78	... ...	9,30,371
1878-79	... ...	12,03,222
1879 80	... ...	12,98,097
1880-81	... ...	14,08,310

Not only has the import of cigars been checked, but India is now exporting to a considerable extent, the total exports of all kinds of tobacco during 1880-81 having been as follows :—

			lbs
Unmanufactured	... ...		13,267,325
Manufactured—			
Cigars	... ...	207,005	
Other sorts	... ...	198,811	
			405,816
		Total ...	13,673,141

Of the unmanufactured tobacco, about one-third went to the United Kingdom, one-third to Aden for transhipment to Arabia and Africa, and the remainder elsewhere. There is room for a further increase in the exportation of this article, but India will never be able to carry on this trade to advantage till she produces at least half a ton per acre. In America, the outturn is occasionally over a ton per acre, while in India it is very much less, the average produce per acre being in the Punjab 780lbs., and in the Central Provinces 199lbs. The exports of tobacco must, therefore, be checked, from the inability of the farmer to make a sufficient profit in its cultivation.

A MODEL REPORT.

WE commend to the various report-writers of this report-producing land, the brief and succinct report of the Professor or Minister of Agriculture for South Australia, regarding the organization of an Agricultural College. From the space which it occupies in our columns, it may be seen that the whole report would not cover more than three pages of foolscap ; and to those conversant with agriculture and its importance, it will be apparent that in this brief space, Professor Custance has stated the chief reasons and advantages that may be derived from an Agricultural College organized, and worked on a common-sense basis. It is quite refreshing to us here in India to come across a report-writer who can say his say and state his case within such short limits. It is probably hopeless, at this time of day, to expect that Indian officials will in

the matter of cumbrous, long-winded reiterated reports, change their ways; but it might be good for some of India's report-manufacturers, and would certainly be an unspeakable blessing to those of the present and succeeding generations who may have to wade through the compilations yearly poured forth from the various Secretariats, if, reading some such simple, short, straightforward statement as that noticed, they should "take a thought and mend." The multitudinous reports which are periodically called for, written, printed, re-written, "hashed up" and re-printed, are "quite too awfully" imposing; and men who would serve India better if they moved over their districts, came in contact with their subordinates, and saw things with their own eyes, and censured, and approved on the spot, are compelled to waste some of the best months of the year in writing long-winded reports, which some who write and many who read may wish heartily at Jericho. The best work in India is not done either by reports or report-writers, though both have their place—in our opinion, an unduly prominent place, as reports go in the present day. The official who does the best work is he who makes his individuality felt through the long line of his subordinates and upwards, by his straightforward, manly utterances, through gentlemen's gentlemen, secretaries, assistants and potentates, to the ear of the great body of public opinion, which in the end makes itself felt through triple bands of red-tape and circumlocution.

On the present occasion we have no intention of doing what has frequently been done in our columns, namely, advocating the claims of agricultural teaching for India. The short report of the South Australian Professor, with certain exceptions, is as applicable to this country as the colonies, and in the Madras presidency steps in the right direction have already been taken. Bengal may probably follow in the same path, when it gets a Lieutenant-Governor who believes that agriculture is quite as important to the welfare of India, as railways and roads.

The following is Professor Custance's first report to the Hon. the Commissioner of Crown Lands regarding the organization of the proposed Agricultural College for South Australia:—

"To the Hon. the Commissioner of Crown Lands.

"Sir,—In accordance with your instructions, I have the honour, to submit for your consideration the following brief notes regarding the organisation of an Agricultural College for South Australia.

"It may be as well to mention that England possesses two Agricultural Colleges, the Royal Agricultural College at Cirencester and the College of Agriculture at Downton, near Salisbury—both self-supporting and working satisfactorily. There is also a Chair of Agriculture at Edinburgh University.

"The Imperial Model Farm of 1,200 acres and School of Agriculture at Grignon in France, the numerous experimental stations in Germany, the Cornell University in the State of New York, the Glasnevin School of Agriculture in Ireland, and the Imperial College of Agriculture and Experimental Farm at Kornaba, near Tokio, Japan, are some of the best examples of Agricultural Schools.

"South Australia does not at present possess a school for agricultural instruction, investigation, and research, yet agriculture is of all occupations the one which stands in need of the safeguard of a sound scientific judgment and of scientific knowledge. No one will deny that at the heart of all large questions, political or social, affecting the prosperity and welfare of a country there lies, hidden it may be, but always real, the question, 'How can the greatest produce be secured at the least expense from an acre of ground?' The problems of agriculture are scientific problems of the highest difficulty and complexity; the adequate preparation of the ground for the growth of a given crop, the prevention or cure of the diseases of crops, &c., are subjects which, seriously examined, expand into a whole series of problems, taxing to the utmost the fullest and most advanced knowledge; hence the necessity for an institution where students can be trained for the work of practical and scientific farming, and where investigation and research can be properly conducted.

"Some of the advantages to be derived from an Agricultural College and Experimental Farm in connection therewith may be briefly referred to. A number of students, after receiving a practical and scientific training, would be fitted for conducting the business of farming more profitably, and by their example probably induce a better system of farming in the country. Regarding the future prospects of farming in South Australia, the advantages of an Agricultural Institution and Farm will be acknowledged by every one.

"The College could to a certain extent perform the work of an agricultural department in the collection and publication of agricultural information, &c. Enquiries from different districts could be received and answered, and information supplied when desired by a course of lectures or otherwise. Investigation and research should be carefully and systematically conducted. Lectures could from time to time be delivered in different districts by the Professor of Agriculture.

"The Farm in connection with the College should be an example of what can be accomplished in South Australia by good farming, the proper cultivation of the land, and the use of suitable manures.

"Experimental plots on a portion of the farm would be of great interest and value. New crops, &c., might be tried; if successful, a portion of the farm could be devoted to the growth of seed for distribution. A series of experiments (under different conditions of soil and climate) might be conducted in various districts. The breeding and rearing of stock might also receive attention. The situation of the College should be healthy, in a farming district, and easy communication with Adelaide would be an advantage.

"The cost of the institution and working expenses need only be moderate. If a sufficient number of students attend the College it might become self-supporting or nearly so. The size of the farm might be from 1,000 to 5,000 acres, though a less area would be sufficient at first. The Professor of Agriculture would require one properly qualified assistant.

"In conclusion, allow me to say that an Agricultural Institution and Farm, where both the practice and science of agriculture may receive the attention they deserve in an agricultural community, should be, I think, commenced without delay.—I have, &c.,

"JOHN D. CUSTANCE.

"July 29, 1881."

POUDRETTE.

THE conversion into manure, and the incorporation with the soil of all the night-soil and excreta of towns and villages in this country is a question of vital interest to the Indian cultivator, and as far as municipal and cantonment committees are concerned, the Poudrette question is the most important in a sanitary, and it may be said economic, point of view with which they have to deal, unfortunately it is one which has not received any very general solution.

In England and Europe the ultimate disposition of all refuse matter of towns, human excreta included, is effected by means of elaborate systems of sewers pushed and cleaned by the agency of water. In certain cases the collected sewage is applied direct to the soil as a fertilizer; but where the natural conditions are not favorable, the refuse matter is, under certain restrictions, turned off to the nearest natural water-course, the sea or river as the case may be. In India in the smaller towns where, owing to want of funds, European systems of sewage and water-supply are (at present) impossible, we are content to allow the liquid refuse to run off by open drains, and dispose of the human egesta by what is termed the "dry earth system"; a system, by the way, which it was once believed would obviate all necessity of sewers and drains, and that every town wherein it was applied would be a model of cleanliness at a relatively small outlay.

We are not concerned at present to discuss the merits of the controversy Liernieur.—Dry earth *versus* Sewers; but suffice it to say that the chemists and faculty of engineering who were the chief supporters of the underground sewage system, have demonstrated the accuracy of their reasoning by the success which has invariably attended the construction on correct *principles* of underground sewers; the sewers carry off everything solid or liquid, and form a complete system: whereas the dry-earth system provides for the removal of $\frac{1}{20}$th only of the whole refuse matter of a town, leaving the other $\frac{19}{20}$th positively untouched. Towns are bound to get rid of their night-soil in such a manner that the health of the population shall not suffer, and at the same time dispose of it in such a way that it may minister to the wants of the suburban agriculturists. Experience gained in this country as well as in Europe has shown that to Poudrette, a certain commercial value can be assigned, though a difficulty has been met with in inducing cultivators to use it. Yet when presented to them in a perfectly inodorous form, inoffensive to touch or smell, their

prejudices have soon vanished before the most powerful of all motives—self-interest.

The Indian market-gardener has not a very extensive knowledge of *Agricultural Chemistry*, but he knows perfectly well that the substances composing his body are derived from the food of which he partakes: and that the food is the product of certain crops which he cultivates on his fields, and again that on the poverty or richness of his soil depends the healthy germination and subsequent development of his crops: moreover that unless certain substances, such as stable dung, compost, etc., are returned to the soil, he cannot maintain its fertility intact. He is thus, in his own imperfect way, able to trace out a complete circle or chain of natural causation, and he is also well aware that human and animal ordure have almost the same effects as stimulants to the soil, animal ordure being, however, a degree less valuable than human fæces, which, unfortunately, he is seldom able to procure in a properly dessicated and inoffensive form, hence his disinclination to use Poudrette. In some parts this disinclination amounts to a positive aversion, so much so that the "Arain" or Saini will not take it even if given gratis.

It is here that cantonment and municipal committees should step in, instruct both by precept and example, doing what is possible to remove the prejudices of the people.

In China and Japan the peasantry collect the excreta of their own households, and those who have fields or gardens bordering the main roads, sink close to the pathway large open mouthed vessels brim deep in the ground, and request travellers to ease themselves therein.

In Japan a regular trade is carried on between towns and villages in night-soil. The Japanese cultivator, however de-azotizes the excrement, allowing it to ferment in the open air. The mass is brought up into a liquid state by copious additions of water, stirred up with a huge ladle and after fermentation has ceased, and all volatile matter given off, the liquid when about two months old is applied as a top-dressing to the crop.

In China solid forces only are collected and pressed into sun-dried bricks forming an article of commerce, notwithstanding all this, travellers in Japan and China bear testimony to the total absence of the awful nuisance experienced in every Indian village, which is caused by the inhabitants resorting to the fields and water-courses, men and women promiscuously, like heads of wild beasts, in a manner subversive of all morality, cleanliness, and decency."

In England it was once imagined that all the waste and refuse matter of every town could be returned to the soil, that guano and other imported manures could be dispensed with. Baron Gustus von Liebig once said, "It is neither fantastic nor ridiculous to believe that without purchasing foreign manure, by a judicious utilization of the sewage of towns and villages England would be able to dispense with the importation of food from abroad.

The more moderate views of the English school demonstrated that, however desirable it might be found to return all refuse matter to the soil as manure, yet these sundry obstacles, such as financial considerations, coupled with unfavourable natural conditions of soil and climate which were insuperable difficulties to the universal realisation of the great German theory.

Like stable dung, Poudrette varies in manurial value according to the age and food of the individual producing the fæces as well as to the subsequent treatment it undergoes in trenching or in the manure pit.

The human body takes in—

Food solid and liquid, 75 per cent. of which is water	71·40
Oxygen through the lungs	25·60
	100·00

The loss is—

Water through the lungs...	31·80
Carbon Doxide	30·20
Evacuations	34·60
Other losses	·50
	100·00

Solid fæces contain in every 100 parts the following substances:—

Water	75·00
Organic matter	22·13
Oxide of Iron...	·13
Insoluble Silica	·87
Lime	·43
Magnesia	·38
Phosphoric Acid	1·07
Sulphuric Acid	·06
Potash	·30
Soda	·08
Chloride of Soda (Na. cl.)	·05
	100·00

Human Urine contains in 100 parts—

Water	93·20
Urea, Nitrogen and organic matter	4·90
Phosphates of Lime, Soda, Magnesia and Ammonia	·60
Sulphates of Soda and Ammonia	·70
Chloride of Soda (Na, cl.)	·60
	100·00

Each human being on an average voids daily—

	lbs.	oz.
Solid Fœces	0	4
Urine	3	0
	3	4

And the dry matter in the excreta of a mixed population does not exceed 50 lbs. per annum, which is supplied as follows:—

Solid Fœces 4 oz. per diem	containing 1 oz. dry matter	23lbs.
Urine 3 lbs. „	„ 1¼ oz. „ „	34lbs.
	Total ...	57lbs.

giving nearly 9·75lbs. of Ammonia, five-sixths of which is derived from the urine.

If the liquid excreta were properly collected in India and the volatile matter fixed, the Poudrette would have a very high value in an agricultural point of view, as it would then form a most powerful fertilizer and being cheap would be within the reach of the poorest cultivator. The only way in which it is possible to see the general utilization of Poudrette by rural communities is for municipal and cantonment committees to manufacture it on correct principles. At present this is *never* done, at least in Upper India, and this defeat forms a serious blot on the administration.

The process is so simple, easy and relatively cheap, that it is really a matter of surprise why greater attention has not been paid to this subject.

Mr. Robertson, of the Madras Agricultural Department, says "Manufactories for the preparation of Poudrette have been established near many European towns, and the objectionable characteristics of such manufactories would not be greater in this country. Indeed, I think that we have in our dry atmosphere and high temperature, excepting during a small portion of the year, conditions highly favorable for the manufacture of Poudrette, provided always that proper measures are taken to keep back the putrefactive process which in this country operates so quickly. In order to manufacture Poudrette properly, and make it available as a cheap universal manure, the following conditions are essential:—

I.—The exclusion of all moisture during the process of preparation.

II.—The use of cheap and powerful deodorizers.

III.—The storage of the material *under cover* preparatory to its being used by the cultivator.

Unfortunately these conditions are seldom, if ever, maintained, and what is worse latrines are seldom, if ever, properly built, being in most cases mere structures of *ka pa masonry*, consisting of four walls enclosing a certain area of ground open to the heavens, round these walls are ranged seats or "kadamchis" on which the people squat. Evacuations solid and liquid are allowed to fall on the ground. The renal excreta being removed whilst the urine is allowed to soak into the ground. Fresh *sand* is thrown in between the kadamchis from time to time, which, however, does not prevent the existence in perpetuity of the awful nuisance:

foul smells, the result of gaseous decomposition being given off, poisoning the air far and wide.

In the mean time, the solid fœces are carted off to the trenches, thrown in with a certain proportion of soil, which never by any chance happens to be dry clay, and the trenches are thus by degrees filled up.

Such is the system now in force, and one which is wasteful, unsanitary, unscientific, and consequently utterly irrational. The general failing complaint about Poudrette in this country is, that when used it demands such a copious and extravagant supply of water to the crop inorder to prevent it being *burnt up*. Now this is a serious defect, arising from the excess of volatile matter in the improperly dessicated manure, and the evil becomes more glaring when we recollect that liberal supplies of manure rich in *organic matter* actually increases in a high degree the hygroscopic power of the soil, or in other words, increases its drought-resisting properties.

The best deodorizers or disinfectants of human excreta are clay ashes, caustic lime, animal charcoal and sulphate of iron ($Fe. So_4$.) Clay and ashes are procurable everywhere, the same may be said of caustic lime, only the substance should be applied when the excreta are in a fresh state. Animal charcoal, the refuse of sugar refineries, may by omitted as being procurable in only a few places in India.

Clay is a most efficient deodorizer, and is cheap, at the same time it possesses in a marked degree the property of decolourising liquid filth, depriving it of all offensive odour.

Sewage if passed over and through soil entirely looses its color and odour, and in some places where it finds its way into the river after having fertilized the land, sewage water is found to be purer and freer from offensive and foreign matter than the river water itself.

Solutions of ammonia, potash, soda, and other salts if passed through soil, come out positively filtered, and we fail to recover the constituents so abstracted, by what is termed the capillary absorptive power of the soil. This is a property exhibited by all, but in the highest degree by clay soils. Clay is capable of being divided into an almost impalpable powder, and as all soils are a mere aggregation of molecules with a varying density and power of cohesion amongst themselves, it follows that that soil the molecules of which are capable of the finest and minutest subdivision presents, of course, the greatest area to the atmosphere, and the greater the surface attraction, the greater the capillary power exerted by the soil.

Where a column of sand by capillary attraction will not raise water more than 24 inches, a column of clay finely sub-divided will attract and draw up water through its pores 36 inches from its base: consequently we see how *dry* and *pounded* clay when applied to night-soil in its fresh state absorbs water and seizes on the other organic compounds, preventing further decomposition, fixing the ammonia, carbon, dioxide, &c., contained in the fœces, rendering as it were inert until by the action of tillage these substances are again, though in a different form, brought into a state available as plant-food and assimilable by the crop.

In preparing Poudrette it is essential to bear in mind—

I.—The vessels which receive the evacuations should be either—

(*a*)—Iron ashphalted within and without.

(*b*)—Glazed earthenware.

(*c*)—Ordinary native-made chatties, semi-porous, flat, open-mouthed vessels: these should be dipped into heated coal tar, taken out and allowed to cool.

II.—The vessel or pan should, before being placed between the kadamchi or under the seat, have a small quantity of dried clay mixed with chopped straw or leaves sprinkled inside.

III.—As soon as the evacuations have been voided, the pans should be withdrawn, and taken off to the Poudrette shed, sprinkled with ashes, to which should be added about 3lbs. of *dry pulverised clay*, the whole substance well mixed up and then emptied into the Poudrette vat.

IV.—The amount of clay required to completely deodorize the excreta of each human being will not fall short of 4lbs., add to this half a pound of ashes and half a pound of dry straw vegetable refuse or a total of 5lbs. per diem, allowing clay to weigh 120lbs. per cubic foot, we have in round numbers, taking 1,000 souls as a convenient factor and neglecting the difference in bulk and weight of the 5lbs. of mixed ashes and straw $\frac{5 \times 1000}{120} = 41 \cdot 66$ and $41 \cdot 66 + 30 =$ 1250 cubic feet of clay per mensem per mile of population.

V.—In preparing the Poudrette the contents of each pan or receptacle should be separately deodorized, and not thrown in indiscriminately with insufficient quantities of clay.

VI. The deodorizing power of clay is practically unlimited, and provided the one essential of dryness be preserved, *the same clay earth may be used or passed through the latrine four and five times over with perfect safety.*

VII.—In order that no detail of the process be omitted, one or two or more cinerators should be constructed in order to maintain a constant supply of ashes.

VII.—Dry sweepings, grass, leaves, vegetable refuse, and the thousand-and-one abominations which are comprised under the head of "koora" would form excellent fuel for these cinerators. At present no inconsiderable portion of this "koora" is sold to the kumars or brick-burners, being lost to the soil for ever, whereas if reduced to ashes and utilized in the preparation of Poudrette a very important reform would have been effected, and the monoply enjoyed by certain members of the sweeper community in virtue of what is termed their prescriptive rights would be abolished.

IX.—The central Poudrette sheds or depots should be so built as to be completely water-tight and dry, and sufficiently large to be capable of sub-division into two compartments; one for seasoned, and the other for unseasoned Poudrette.

X.—Poudrette should be allowed to season under cover for at least four months preparatory to use.

In light sandy soils 15·20 tons may safely be put down yearly to each acre. For maize, wheat, barley, sorghum, cucurbitaceous and leguminous crops, Poudrette will be found a most valuable and powerful fertilizer. It is on record that on the Experimental Farm at Broach (Bombay), a field of sugar-cane heavily manured with Poudrette gave an outturn of 49 tons of cane per acre or 110,760lbs. The average outturn in Louisiana, the best sugar-producing State in the Union, does not exceed 60,000lbs. per acre.

In places where the disinclination to use Poudrette is only too well founded, it will take some time to remove the prejudices of the ordinary "fat," and this can only be done by precept followed by practical example; for instance, its extensive utilization in Government gardens or Experimental Farms, or native gentlemen might be induced to use it by being guaranteed compensation in case of loss. Under any circumstances the manure would have to be given *gratis* at first, but when presented to the people in the perfectly inoffensive form their prejudices would soon vanish.

In the Punjab and Upper India, where the soil is sandy and porous, the addition of large quantities of Poudrette would be attended with the most favorable results. This light sandy soil is almost incapable in the hot season of supporting vegetable life, unless it be deluged with water. A great physical property indispensable to vegetable life is here wanting, yet if the soil be supplied with Poudrette, or any manure rich in organic matter, we find that the addition of the clay and organic substances increase the hygroscopicity of the soil to a high degree, enabling it to retain and absorb watery vapour from the atmosphere.

Pure sand, after being ignited in a crucible and subsequently exposed to the atmosphere, was found capable of absorbing only 0·12 per cent. of moisture, whereas the same sand, again exposed and mixed with organic matter, took in ·70 per cent. of its own weight of watery vapour.

A clay soil well tilled will absorb and retain 30 per cent. of moisture, and an addition of organic matter will still further increase its hygroscopicity.

The great want of the soil of India is organic manure in order to enable it to—(I) more effectually resist drought, (II) render more solvent the earthy phosphates, salts of soda, potash, &c., contained in the soil, thereby rendering them assimilable as plant-food.

Ordinary atmospheric air contains about 4 volumes of carbonic acid per mille, whereas in well manured soils after rain, Boussingault found as much as 9 per cent. of this compound in the soil.

Professor Voelcker in analysing dry night-soil from a pail in England found that, before being used, 10 tons of dry earth contained nitrogen 62lbs., phosphoric acid 36lbs.; and that—

						Nitrogen.	Phosphoric acid.
10	Tons of dry earth once used contained				...	74	52
10	"	"	twice	"	" ...	84	88
10	"	"	thrice	"	" ...	102	102

Now a wheat crop yielding 28 bushels of grain, 23 cwt. of straw, will abstract 193·93lbs. of fertilizing matter from the acre of ground composed as follows :—

	Grain.	Straw.	Total.
Potash	10·11	20·70	30·81
Soda	1·20	2·84	4·04
Lime	1·01	8·53	9·57
Magnesia	4·80	2·23	7·03
Sulphuric Acid	0·32	3·55	3·87
Phosphoric Acid	16·22	3·16	19·38
Silica...	0·43	73·47	73·90
	34·12	114·48	148·60
Nitrogen	29·20	16·13	45·33
	63·32	130·61	193·93

From Dr. Voelcker's analysis we see that an application of 10 tons of Poudrette would return to the soil more fertilizing matter than could probably be abstracted in three or four croppings.

It is stated in the record of the Poona experiments on night-soil, published in the *Gazette of India*, that the cultivators were enabled to use the Poudrette when eight days old, and that ashes were found to be the cheapest and most effective disinfectant.

The Poona results were certainly most gratifying, but it is extremely doubtful whether ashes will always be found as cheap as clay; and it is equally doubtful whether in places where irrigation is not available, the Poudrette could be safely utilized within a shorter space of time than three or four months. At places where canal irrigation is available, cultivators could of course deluge their fields with canal water, thereby mitigating the evil effects which invariably attend the application of raw and imperfectly dessicated fæces to the soil. And it here behoves us to consider the true economy of such a process, and whether the remedy is not almost worse than the disease.

As before remarked, to properly dessicate the fæces of each adult, at least 4lbs. of dry matter per diem is required : for each 100 souls 4000lbs. of ash would be required. Now, each 100lbs. of dry vegetable refuse could only yield 8lbs. of ash after complete incineration, consequently about 50,000lbs. of dry substances would be required ; and where could such an enormous amount of dry sweeping be procured for a large town where the population could possibly number 1,000 × 30 ?

Clay can easily be delivered at any latrine for a sum not exceeding Rs. 2 per hundred cubic feet. Assuming that the population is 20,000 souls, all of whom frequent the latrines, we have $\frac{20,000 \times 4}{120} \times 365 = 2,43,090$ cubic feet and $\frac{2,43,090}{3} = 81,030$ or say 82,000 cubic feet at Rs. 2 per hundred cubic feet = Rs. 1,640. When fresh earth is used every time we should find that $\frac{20,000 \times 4}{120} \times 365 = 2,43,090$ cubic feet at Rs. 2 per cent. would bring our working expenditure in dry earth alone up to Rs. 4,800 per annum. Our Expenditure or rather comparison between the expenses of the two systems does not end here.

In one we have 100,000 cubic feet of earth supplied at the latrines, this, plus the deodorized excrement only, has to be removed.

Under the system now in vogue we have to provide at the latrines 2,43,090 cubic feet, this plus the deodorized excrement has to be disposed of so that in the matters of supply of earth and carriage the present system cost more than it should in the ratio of 3·1.

Under the system proposed, *viz.*, that of passing the earth three times through the closets, not only is the resulting manure very much enriched in fertilizing properties, but the committee's working conservancy expenses are considerably reduced.

Poudrette prepared according to the method adopted at Poona becomes in reality a special manure, inasmuch as its utilization is only possible where irrigation is available, and this is a serious evil. Poudrette not only contains all the inorganic constituents essential to a healthy development of vegetable life, but is singularly rich in nitrogen and other organic substances which are so sadly deficient as a rule in most Indian soils, owing to unscientific cropping.

The great want of Indian soils is organic manures, and scientific agriculturists have repeatedly demonstrated that a more liberal supply of these substances enable soils to dispense to a great extent with the irrigation water now *wasted* on our fields. A healthy crop of cereals has been found to exhale during its growth, water in the proportion of 250—300 parts by weight for every part of dry matter elaborated, and a crop of wheat weighing 2½ tons per acre will transpire 750 tons of water through its leaves alone, or an amount of water equal to a rainfall of more than seven inches.

M. Schiffmayer (Madras Agricultural Department) says : "Plants often exhale from their leaves up to seven times as much water as they receive by rain, so that 80 *per cent. of the water must have been absorbed from the atmosphere*, it must be admitted that the absorption of water vapour by the soil is a power of nature deserving the greatest consideration." In a previous remark in the same paper it is said. "A soil having much organic matter may when properly tilled in many instances receive *all* the water required for the production of crops by air irrigation, that is to say, the atmospheric air circulating in the soil can supply all the water needed by the plants."

Poudrette properly prepared and utilized accordingly, would go a long way towards counteracting the evil results attending the baneful and never-to-be-sufficiently deplored practice of burning cow-dung as fuel.

This is a question which will soon engage the attention of the new Department of Agriculture, and one in which we have every reason to believe and count on the hearty and zealous co-operation on the part of Presidents of Municipal and Cantonment committees.

Of all manures Poudrette is the cheapest, and for all practical purposes the most efficient, and we can only expect to see Rural communities use it when they see the excellent results attained in the vicinities of large towns and cantonments.

NOTES FROM A COTTAGE GARDENER.

IV.

SURFACE-DRESSING AND MULCHING FRUIT TREES.

(Communicated.)

SOME forty years since it was a regular custom to *dig*, annually, all fruit-tree borders, for it was considered that when the surface looked smart and fresh, there was, of course, good gardening beneath! As for minding the destruction of a net-work of those minute root-organs, termed fibres, why, it was not worthy of consideration, so long as the big black roots, which start downwards, were safe. In these times, sensible people not only forbear to dig over the roots, but actually set a decoy over them, to tempt these fibres upwards, and to secure them when obtained. I need scarcely say that the two practices are the very antipodes of each who would practice rational gardening to the very opposite nature of the two operations : surely no thinking person can pass them by as trifles.

And, perhaps, I may be permitted to show the necessary consequences of each operation respectively. There can exist no doubt of the following facts :—first : deep roots are in a cooler medium, during the growing period, than surface roots ; secondly, they have a tendency to produce wood of a less fruitful character than surface fibres. It is pretty well-known that the air we breathe, and the soil we tread on, are perpetually interchanging heat with each other ; and that, on each returning spring, the earth has to be warmed anew, principally by borrowing from the atmosphere, to be repaid most scrupulously. If this be admitted, it is evident that the surfaces of the soil must first be heated, and this being the case, it becomes necessary to inquire whether the ordinary heat of the soil, without solar influences, would be congenial to fruit trees. It is, surely, needless to answer this. If, then, roots enjoy a considerable degree of warmth, why not shape our operations and practice accordingly? I have years since paid close attention to the results arising from deep digging over the roots of fruit trees ; and have even known what might appear anomalous results accruing therefrom. The following are the usual phenomena presented by a pertinacious course of practice of the kind. The trees become barren, their side branches,

fall gradually away, causing them to assume a lean and gawky appearance; they are apt to produce much watery or immature spray from portions of the tree which had lost the true or original branches; and that spray generally springs forth about midsummer and too late to be of any service to the tree, or the terminal growths are apt to become long jointed, and, in many cases, the joints of the shoot die, or become diseased. Moss is apt to prevail on the stems, if the trees be of some age; and, in general, trees thus circumstanced, are a prey to numerous insects, caterpillars, &c. These are a few of the evils; but, in addition, it will be found that what may be termed the principal young wood, is produced late, and by consequence continues growing late, and other enemies seem particularly attached to the first made wood of such trees. I have seen orchards thus attacked annually, until they become utterly worthless, the owners still hoping on.

But now let us for a moment cast our eyes on the trees undug and well rooted in a proper soil, with abundance of fibres nestling just under the surface. It is almost needless to look for moss on the stems of trees thus situated, their bark generally shines with a polish of a very different character. Their early made shoots progress with rapidity at the very period when the ill used trees receive their first snubbing with blight. But their young shoots are compact and short pointed, presenting altogether a very different appearance from the attenuated character of the young wood of the other class. Much less inferior or watery spray will be produced; indeed, with trees well managed on the platform system, scarcely any. The trees having freely and heartily made their first growth, generally begin to solidify about the period when the ill-used trees are beginning to ramble? And if any second growth is made, it is short, firm, and soon ended. As for dying points, there will not be much trouble concerning them, if the surface soil is genial and undug; unless top roots have been permitted, when the trees will be in part liable to the grievances complained of in the other class.

It is almost needless to add here a description of the results in the one case, dwarf, compact, comfortable-looking and fruitful trees; in the other, gawky and barren skeletons, a discredit to the gardens, and how could it be otherwise? It must be obvious to any one, on the slightest consideration, that when the surface roots of any tree are annually mutilated, for eight or nine inches in depth that what roots the tree has remaining, must be several weeks later in receiving the necessary amount of ground heat produced by the return of summer, than trees whose fibres are just beneath the surface. The effect is, as before stated, the well-cared-for tree makes its early growth with the adjunct of a lively root action, thus bidding defiance to the extreme ravages of insect foes. The tree, dug over, is impelled to growth in the shoots, by the heated atmosphere weeks before the deep roots are put in active motion; here is, surely, some difference in condition! The early growths of the latter are almost sure to suffer in some way; they are in little better position than a cut-down stump, thrown across a stream; such as we all have seen many a time, attempting to shoot as springs return. The first growths being foiled, we arrive probably at or near midsummer, when the sun has warmed the soil to a greater depth, and the ill-fated tree, clinging with tenacity to life, makes another bid for an annual growth. But, as before observed, our autumns are not long enough to mature this growth, and, at last, a morbid condition is the consequence, and the cultivatior cuts the tree down in despair. I have stated this much, as paving the way to a few remarks on the immense benefits arising from a system of coaxing surface or shallow root. This is called by various names as surfacing, mulching, top-dressing, &c. But here let us distinguish a little. These various names should be reduced to two processes, which are, indeed, somewhat distinct, *viz.*, mulching and surface-dressing. *Mulching*, in the practical gardener's acceptation, means applying half-rotten manure over a tree's roots, to prevent them becoming dry. It is intended to obviate the necessity for the watering pot. *Surface-dressing* is specially intended to induce, and preserve, surface roots.

Now, there are more ways than one of performing these operations. As for mulching, to preserve moisture, that needs little description; it seems specially intended to avert solar influences, which we invite, in these times, to tender fruits; and is indeed confined chiefly to trees of coarse or hardy habits, and which depend not so much on ground heat. With regard to surfacing, we must remember two things: first, that the material should have a capacity for receiving and transmitting warmth; and secondly, that it may prove ultimately an abiding medium, adapted to the needs of the roots thereby induced. I find nothing superior to chopped loamy turf and vegetable matter, such as half-decayed tree leaves; these, in about equal quantities, furnish an excellent material. If the loam is very adhesive, mix some charred rubbish with it. Indeed, I prefer the latter course, as it makes the whole darker; and doubtless assists in the absorption of heat, a material point with tender trees.

I here advise that a few main points be kept well in view. In the first place I urge that spring is the most eligible period. I would have this surface-dressing retain surface moisture, when it can be secured. This, however, pre-suppose that the trees are on sound platforms, or otherwise so situate as that no stagnation can possibly occur. It is of the utmost importance, with tender kind of fruits, to permit the solar rays; applications of this kind should, therefore, be withheld until the object be accomplished. And it is of importance that this covering should succeed on the heels of a liberal spring rain, provided the preceding period has been somewhat dry, which is frequently the cases. Surface-dressing in my opinion is, therefore, best applied in the spring, but as to weather we must of course leave a margin on its behalf.

We may now consider the thickness most eligible. It may have been observed that if the compost applied is one-half vegetable soil, such will diminish by decay into a very small compass; therefore, the loam alone may be counted on as permanent depth. If annual dressings are applied, I consider two inches sufficient; if biennial, three inches may be applied. Care should be taken, during the succeeding summer, not to cut away by any operation the surface fibres, which are sure to be encouraged thereby. If any weeds appear, hand-weeding may be resorted to.

Here let me point to the evil influence of tap or forked roots. If trees are carefully transplanted, and roots pruned whilst young, these roots will seldom occur; but if such has been neglected, care must be taken at the first planting to cut away all coarse and fibrous roots having a downward tendency.

The surface-dressing here recommended is of much value to all trained fruit trees; and in course of decomposition become filled with fibres. The spade is of course banished from the dressing, and as it solidifies, it becomes perfectly united to the body of the soil.

Whether, then, cultivators choose or find it convenient to use surface-dressing annually, biennially, or as they feel inclined, it is a principle of high importance to the culture of tender fruits, and I cannot recommend it too strongly to their notice.

EDITORIAL NOTES.

Much intelligent work is being done at the Bhadgaon Experimental Farm. From what we learn from the half-yearly reports, this farm has less theory and more practice in the conducting of the experiments than are displayed in other farms throughout India. During the half-year ending 15th July, 1881, the farm actually made Rs. 1,557 as profit after paying all expenses, including Rs. 500 towards the salary of the Superintendent, and over Rs. 1,000 to Government for rent and taxes. From the extent of the land under the control of the farm, this may be a very small profit; but it must be remembered that financial success is not looked for or expected. What is desired is that an effort be made to find out better modes of conducting farming operations; modes which shall bring assured success, and which shall not be beyond the resources of the ordinary cultivator. These, the Superintendent of the Bhadgaon Experimental Farm, Mr. Stormont, seems to aim at. The cotton fields, for instance, 154 acres in extent, yielded an average of 150lbs. of clean cotton per acre, an average not so high perhaps as is obtained in America, but immensely beyond the Indian average. Twelve-and-a-half acres of [illegible] an outturn of 7½ cwt. of jaggri per acre, worth on the spot Rs. [illegible]. Considerable success followed

the cultivation of green crops for fodder; fifteen acres of *juar*, Lucernes, Guinea grass, and Teosinte gave 35 tons per acre. The principal part of this outturn was from Teosinte (*Reana luxurians*) which the Superintendent says, "stands unrivalled for a *kadwal* (annual) crop as Lucerne does for a perennial cultivation." This is a point the importance of which cannot be too frequently impressed on the ryot—the cultivation of a crop for cattle-feeding alone. We shall never have good cultivation till we plough deeper, and this can only be managed by a material improvement in the breed of draught cattle, and this must depend very much on the way they are fed. Until the ryot is out of the hands of the bunneah, we cannot hope for any improvement in this respect, the bunneah naturally insisting on the cultivation of those crops which will go to increase his own business. In connection with what is being done with fruit trees, the Superintendent gives us this legend :—

"The mango grove in course of formation is making satisfactory progress; the grafts received from Bombay have now taken root, and are growing well; from these a number of grafts have already been obtained, and it is proposed to plant the whole extent (15 acres) with the best kinds. For this purpose efforts are being made to propagate from the famous Borshat *amb* at Lahora; the fruit of this tree is celebrated for its fibreless flesh and delicious flavour, the seed being so much suppressed as to resemble half an ordinary mango stone; and as usual in such cases, being entirely unfertile, all recorded attempts to raise saplings from them having failed. In the early history of the tree, before its sanctity was impaired, a single crop of fruit, it is said, would sometimes realise as much as Rs. 500. The legend in connection with it is as follows:—About two centuries ago a Lahora *kunbi*, engaged in drawing water for his garden, stopped his *mhote* and seated himself on the well-top for the purpose of taking his midday refreshment, consisting of a piece of bread and a green mango. A holy *fakir* coming up, the *kunbi* religiously divided with him what he had, slicing the mango in two for the purpose. After eating, the satisfied *shah* blessed the half seed and planted it on the spot, charging the *kunbi* to water and attend to it, and it would grow up to be an unfailing source of wealth to his family for many generations. The steady fulfilment of the prophecy, it would seem, was only interrupted by the introduction of the survey, when the tree became the property of Government."

The experiments recently tried on the Cawnpore experimental farm have been of a more than ordinarily practical character. Two sets of experiments in deep ploughing and inversion of soil were tried, and though they were perhaps not quite conclusive on all those points on which information was desired, they were at least perfectly conclusive as to the general advantage accruing from deeper cultivation than at present obtains in India. Over eight experimental plots of 200 square yards, portions of which were carefully irrigated, and other portions left unirrigated, the following were the average results per acre, the crop being *sorgo*, grown as a green crop :—

Outturn of green crop	...	...	114·13 maunds.	
Cost of cultivation	...	... Rs.	14	4 0
Value of produce	...	... "	38	0 8
Profit per acre	...	... "	23	1 8

With cotton similarly treated, the results were—

Outturn of cleared cotton	...	...	291 pounds.		
Cost of cultivation	...	... Rs.	13	4	0
Value of produce	...	... "	59	15	9
Profit per acre	...	... "	46	11	9

The benefits of irrigation with deep ploughing were clearly shown during the course of these experiments, and the conclusions arrived at by Mr. J. B. Fuller, with regard to the *sorgo* experiments, were—

"*Inversion of the soil for a depth of six inches, two months before sowing*, increased the outturn by 72 per cent. when once irrigated, and by 100 per cent. when twice irrigated. *Grubbing to a depth of six inches, without inversion*, increased the outturn by 68 per cent. when once irrigated, and by 107 per cent. when twice irrigated, while *inversion of the soil to a depth of six inches immediately before sowing* diminished the outturn by [illegible] per cent. when once irrigated, and by [illegible] per cent. when twice irrigated."

And with regard to Cotton :—

	Increase per cent. On unirrigated plots.	On irrigated plots.
Inversion of the soil to 6-in. two months before sowing ...	135	75
Inversion, but immediately before sowing	119	75
Grubbing to 6-in. without inverting the soil	27	16

These figures require but little comment. Taking first of all the unirrigated plots, we find that deep cultivation gives, in a season in which the rainfall was only ⅕th of the normal, an outturn worth some Rs. 70 an acre, while the ordinary cultivation of the country could only yield Rs. 30. The condition of half-plots 1 and 2 was a matter of surprise to all who saw them; unirrigated as they were, the cotton plant stood thickly on them at an average height of 2½ feet, while in plot 4 (which closely resembled the cultivators' unirrigated cotton fields in the neighbourhood) no plant stood much higher than 9 inches."

This is the sort of experiments we require. In these instances the results, whether good or bad, are patent; there is no doubt as to the effect of deep ploughing under certain conditions, and if we are to benefit by the lessons of these experiments, we must first of all aim at improving our draught cattle, as good ploughing cannot be done by the present breed of Indian cattle.

A considerable amount of profitless guessing has been wasted on the subject of the locality of the "Garden of Eden," but speculation may now cease, as it seems clear this site must be found in the Islands of Seychelles in the Indian Ocean. Seriously speaking, these islands must possess all the qualities which go to make a model agricultural country. Mr. H. Cockburn Stewart, the chief Civil Commissioner, has made a report to the Lieutenant-Governor of Mauritius, which is full of interesting matter. The principal products of the islands are vanilla, cocoa, and Liberian coffee. One hundred and fifty acres are under vanilla, one-half of which is in bearing. This is a large area for such a valuable product. The out-turn of an ordinary plantation is 250lbs. per acre, which realises 80 francs per lb., and this, after paying all expenses of cultivation, leaves a net profit of Rs. 10 per lb., or £250 per acre. A thoroughly well cultivated garden yields 600lbs. per acre, which, with the relatively lighter cost of cultivation per pound, leaves about £800 per acre as net profit. Cocoa or rather cacao appears to grow well, although no exact statistics are given. One hundred acres are under cacao, which comes into bearing from three to five years after planting. Wonderful results seem to have followed the introduction of Liberian coffee. Plants 30 months old are, many of them, 10 feet high, and all are covered with young fruit. Only a small experimental plot has yet been planted, but the success which has been attained will certainly lead to an extension of the industry. Besides these three, which are considered the most important products, there are many others, and among them cloves seem to do well. They have hitherto been cultivated in a desultory sort of way, the lazy habits of the people not being conducive to good cultivation. It also appears that, to save themselves the trouble of plucking the fruit slowly and carefully, the natives have been in the habit of cutting down the trees to get at the fruit easily. Latterly, they have even been cutting down the trees for firewood. Efforts are being made to put the cultivation on a proper basis. Pepper, cinnamon and other spices grow wild, and no attention seems to be paid to them in any way. The soil and climate are admirably adapted for the cultivation of nutmegs, allspice, arrowroot, ginger, saffron and cardamoms, and Mr. Stewart says :

"I am taking every step in my power to impress upon the people of Seychelles the importance of this place as a spice-producing country, and using every endeavour to give an impulse to the nascent desire of the more advanced of the population to adopt such ideas."

He next goes on to say :—

"It is impossible to imagine a country more favoured by nature than Seychelles. Though near the equator, the great heat common

to the tropical countries is not experienced, and hurricanes so destructive to agriculture in Mauritius and Bourbon never visit these islands. The country is notoriously healthy and exempt from all epidemic diseases and endemic fever, and well watered by streams and rivers, and, as I have endeavoured to point out, peculiarly adapted to the cultivation of every known product of the East or West Indies."

Various other articles are mentioned as suitable for cultivation, but we need not go into further detail.

The Triplicane Literary Society of Madras has forwarded the inevitable memorial to Mr. Grant Duff, several matters mentioned in which might be somewhat annoying to Sir Richard Temple, who allows no opportunity to pass of speaking of the prosperity of the cultivators of India. We have extracted the following passage on the important subject of the collection of the land revenue generally, and of the material condition of the cultivators in particular :—

We crave your Excellency's pardon for taking this opportunity to dwell on some of the most important questions connected with the administration of this presidency. We believe the condition of the agricultural class will have soon to receive the consideration of your Excellency. In the midst of the blessings which the peaceful and civilised British rule has bestowed on the country, there are signs to show that the condition of the agricultural class has been far from thriving. One of these signs is the increasing difficulty in the collection of revenue. We give below a statement of the coercive processes that have been resorted to by Government for the past 26 years. This increase in the sale of real and personal property for the realisation of the land revenue, together with the fact that most of the land sold finds no purchasers, proves the growing impoverishment of the agricultural class. No temporary causes, or causes inherent in a transitional state of society, can account for this steady increase in the poverty of the people. The causes are the enhancement of the land tax at each settlement, the imposition of local cesses which, in plain terms, is enhancement of the same, the discouragement of the annual remissions for the bad seasons, and the unusual rigidity with which the tax is collected.

To add to this would weaken the argument of the memorialists ; let the figures speak for themselves.

Few railways will confer such advantages as the proposed line from Raepore to Visagapatam may reasonably be expected to do. When the Madras famine was raging, and its victims dying by hundreds of thousands, wheat was selling in Raepore at 80 seers per rupee, and in many instances the cultivators refused to gather in the harvest, the cost of doing which would have amounted to more than the value of the crop when cut and threshed. This proposed line being principally intended for the purpose of distributing the crops of the Central Provinces over the Coromandel coast, Visagapatam has been wisely chosen. It stands about half-way between the mouth of the Hooghly and the port of Madras. A large trade has hitherto existed between the ports on this part of the coast and the grain districts, but on account of the general shallowness of the sea at or near the coast, the trade is largely in the hands of natives, who run coasting vessels all along the shore from False Point to Madras. At Vizagapatam, however, there is deep water, and large steamers can anchor close in shore, which will be a great convenience when Vizagapatam becomes a railway terminus. This line may be looked on as the first attempt to construct a railway for purely economic and commercial purposes, and apart altogether from military considerations. Hitherto, a speedy means of transporting troops of any given point has been a prime consideration. This line is, however, intended solely to tap the great grain districts, and make supplies freely available all along the coast. The line is to cost about £5,000 a mile, and will be about 400 miles long. This calculation is on the basis of a narrow-gauge line. Although this cannot be said to be a trunk or main line, we would recommend it to be constructed on the broad gauge, on account of the large traffic which may be expected in ordinary circumstances, and of the heavy demand which cannot fail to be made on its carrying capacity in the event of a famine in Southern India or Mysore. The extra cost of the difference between a narrow and broad gauge line would be more than recouped by the saving which would be effected by the speed with which grain could be pushed into a famine district in the course of one season only. This line will bring grain within the reach of the canal running from Madras to Ganjam, and cannot fail to cheapen and equalise the price of grain in that district. On the other hand, the ryots of the Central Provinces will secure a market for their crops, and their agriculture will prove profitable to them. At the present moment, the price of wheat in those districts is so low that it is scarcely worth growing.

Miss Isabella Mechi, writing from Tiptree Hall to the *Times*, says :—

"Among my father's last words were these words—'What is John Joseph Mechi? He must perish and return to the dust from which he came; but the principles he inculcated are vital truths, and shall remain for ever.' In defence of these principles, will you allow me to say a few words? Mr. Pell, in his letter in the *Times* of yesterday, sums up the results of my father's life-long studies and costly experiments in the expression 'farming eccentricities.' Surely the leading features of my father's teaching and practice—*viz.*, drainage of clay soils, deep cultivation, reduction of superfluous trees and hedgerows, enclosure of waste headlands, and concentration of capital—do not deserve to be swept away under the title of eccentricities. In reality, they are precepts of equal soundness and simplicity, capable of reduction to practice either by the small farmer working on his own holding, or by the landlord with larger capital and more extended opportunities. The next important point in my father's doctrine was the management of stock under cover on prepared food and with proper ventilation, thus securing their health, and at the same time economizing their manure. Another matter my father hoped to live to see carried through was the utilization of sewage. In my belief this will be done by-and-bye, when the man turns up with talent to invent a proper means of application, and energy to turn it to account. Our descendants will then probably look back with astonishment at our prodigal waste of material, and disgust at the abominable pollution of our finest river. Alluding to the circumstances of my father's death, and connecting them with his farming operations, Mr. Pell says 'the result was not a success.' I beg to state distinctly that my father's ruin was attributable solely and simply to the failure of the Unity Bank, in which, as a shareholder, he lost more than every shilling he possessed. To his successful farming, among other causes, he owed the delay of a catastrophe which had for some time been inevitable. It must remain a question of taste whether Mr. Pell has done wisely in affixing the stigma of 'agricultural loafers' to the many high-minded and honourable men who from all ranks of society have attended the Tiptree

ing plant. The demand for it is constantly increasing, and the climate of Ceylon seems intended for it.

SOME dissatisfaction must be felt with the decision come to by the Viceroy regarding the rates of freight between the wheat districts of Upper India and the two principal ports, Bombay and Calcutta. The question arose from a reference to the Government on the equalisation of rates from Delhi and Agra to Bombay, by the Rajpootana line on the one hand, and by the Allahabad-Jubbulpore route on the other This naturally raised the point as to the Calcutta outlet, as the grain, once at Allahabad, was 278 miles nearer Calcutta than Bombay, the relative distances being 564 and 842 miles. Now to look for a moment at the relative distances for the Bombay traffic. From Delhi to Bombay by the old route and by the Rajpootana line, the respective distances are 1,232 and 969 miles, while from Agra to Bombay they are 1,120 and 927 miles respectively. We fail to see why the assimilation of rates on the Bombay-Rajpootana section is considered wrong, and the same assimilation thought worthy of adoption as between the old through routes—Allahabad-Bombay and Allahabad-Calcutta. Bombay has many advantages over Calcutta, the principal of which are its being so much nearer the United Kingdom, and its generally lower rates of freights. Calcutta on the other hand has the advantage of being 278 miles nearer the wheat districts, keeping the Rajpootana line out of the calculation. Calcutta, then, will have this advantage neutralised by the assimilation of rates. We keep the Rajpootana route out of the calculation for the present, because it will never offer serious competition to Calcutta so long as the present narrow gauge exists with its consequent double breaking of bulk. Perhaps the greatest advantage enjoyed by the East Indian line over the Great Indian Peninsula line lay in the greater liberality of its management; but that will be of no value under the proposed equalisation. We think his Excellency should have left each railway to make its own arrangements as to securing freight, subject of course to a check on anything like reckless trading.

AT the end of 1878 the Prince of Wales visited Luton, and was much interested in an exhibition in one of the plait-halls of the whole process of making straw bonnets. A stock of wheat stood near the entrance to the room, men cut it in the next corner, and elsewhere drew the fine straw from its sheath. Others bound it in bundles, and next drew the short straws from the bundles and cut them still shorter with a knife. Then the round sherry-cobbler straws were split up with the machine invented by the French prisoners, the women took them between lissom fingers, and out of a chaotic mass of split straws, the "sudden miracle of plait" came into existence. Afterwards girls stitched the plaits together with hands or on the machine and pressed the bonnets on the blocks. An attempt is being made in London to revive an exhibition which proved very attractive. Long rows of girls in white pinafores sit at counters in St. James's-hall, and plait and sew for the entertainment and instruction of visitors. It is a curious and interesting little bit of the gallery of hand industries. The trade is an important one and worthy of illustration. In 1871 it gave employment to 45,000 women and 3,500 men; and through large parts of Bedfordshire, Herts, and Essex, the wages of farm labourers have been for a long time sensibly augmented by the earnings of their wives and daughters in the straw trade. Cheap Chinese straw came to make the coarser manufacture unprofitable. Thereupon, British ingenuity set to work and invented new styles, which caught the fancy of the buyers, and could not readily be rivalled by the Oriental competitors. The straw trade of Dunstable, St. Albans, and Luton has been better since 1878, and the industrious workers have continued to give in two months a marvellous increase of value to plain straws from the chittim wheat of beds, making bonnets of the value of £45 out of a hundredweight of straw worth three shillings.

AN interesting account is given of the process of collecting rubber in a report just issued by the United States Consul at Carthagena. When the hunter has found a rubber tree he first clears away a space from the roots, and then moves on in search of others, returning to commence operations as soon as he has marked all the trees in the vicinity. He first of all digs a hole in the ground hard by, and then cuts in the tree a V-shaped incision, with a machete as high as he can reach. The milk is caught as it exudes and flows into the hole. As soon as the flow from the cuts has ceased, the tree is chopped down, and the trunk raised from the ground by means of an improvised trestle. After placing large leaves to catch the sap, gashes are cut throughout the entire length, and the milk carefully collected. When it first exudes, the sap is of the whiteness and consistence of cream, but it turns black on exposure to the air. When the hole is filled with rubber, it is coagulated by adding hard sand, or the root of the mechvacan, which have a most rapid action, and prevent the escape of the water that is always present in the fresh sap. When coagulated sufficiently the rubber is carried on the backs of the hunters by bark thongs to the banks of the river, and floated down on rafts. The annual destruction of rubber trees in Columbia is very great, and the industry must soon disappear altogether, unless the Government put in force a law that already exists, which compels the hunters to tap the trees without cutting them down. If this law were strictly carried out, there would be a good opening for commercial enterprise, for rubber trees will grow from eight to ten inches in diameter in three or four years from seed. The trees require but little attention, and begin to yield returns sooner than any other. Those that yield the greatest amount of rubber flourish on the banks of the Simu and Asluto rivers. The value of the crude india-rubber imported into the States annually is about $10,000,000.

LAST May, Messrs. Klunder and Co., Soorabaya, wrote to the Madras Government to say that they had forwarded a copy of instructions for cultivating "giant grass." This letter was communicated to the Superintendent, Government Farms, for remarks. The instructions referred to were, however, not received. The Superintendent reported that he had no personal knowledge of the grass in question:—"It is not an Asiatic species, but is indigenous in the region of country lying to the west of the Missouri River, United States, where it is found widely spread. Referring to this grass, in his report for the year 1870, the United States Commissioner of Agriculture wrote: 'The early pioneer, however, has already learned how soon the good native grasses are destroyed by the clipping and treading of domestic animals, and he sees with regret their places immediately occupied. . . . *Panicum cappillars*, *Panicum sanguinale*, &c. &c., worthless weeds and grasses that occupy the soil to the exclusion of every profitable production.' From this quotation, it would appear that the grass has not a good reputation in the country where it is indigenous. Of course, it is possible the grass may have since been improved by undergoing special cultivation and treatment. I cannot, however, recommend that Government should incur any expense in endeavouring to introduce the grass. At the same time, it may be worth while to get some seed and try it here. This I can readily arrange to carry out. I will also write to the Director of Botanical Gardens and Plantations, Batavia, Java, with whom I am in correspondence, and who, I know, will gladly afford any information in his power about the grass."

WE observe that the Maharaja of Mohurbunj and several other rajas, chiefs and zemindars of Orissa, have been agitating for a railway to their district. An influential committee has been formed, and a rough programme sketched out. Their proposal is a light railway connecting Pooree and Cuttack with Raneegunge. Unless it be to intercept the passage of pilgrims to Pooree from the upper provinces, we cannot see any advantage to be derived from fixing on Raneegunge as the point of connection with other lines. Pilgrims as a rule would not object to come to Pooree by way of Calcutta, and there is a shrine already in Calcutta which attracts large numbers of pilgrims; consequently, many of these travelling enthusiasts prefer coming by way of Kalighât. The line should, therefore, start at Pooree, and make Midnapore the other terminus. There are at present many convenient modes of reaching this latter place from Calcutta, and we hope very shortly to have Calcutta and Midnapore connected by the eastern section of

gatherings, and witnessed the experiments conducted at them. In conclusion, I may add that during the last suffering days of my father's life, his thoughts were not so much with himself or his trouble, not so much with family or friends, as with the cause he had long served and faithfully loved so well."

THE value (?) of English names for plants was well illustrated the other day at Glasnevin. While I was there a gentleman came in all the way from London to see the Flame-flower. A paragraph extolling the praises of this glorious plant, &c., had been going the round of the papers, and stating that a mass of it at Glasnevin was worth going a journey to see. Well, of course, as soon as he arrived he asked to see it. "The Flame-flower?" they said. "You must mean the Flame Nasturtium—Tropæolum speciosum." "Oh, no," he said, "nothing of the kind—I mean the Flame-flower; that's what the paper said." Then they said, "Oh, of course you mean the Torch-plant—torch and flame are the same thing;" and he was duly led towards a group of torches in full flame. But it would not do; it was not Tritoma at all. "Was it a scarlet Rhododendron or a Bottle-brush? or was it inside or out-of-doors?" Could not tell. At any rate, it was a large mass, and worth going a journey to see. And here he was at the end of the journey, and no one could show him the fire at all. From the glowing description he was half inclined to fancy that his hair would be singed almost as soon as he entered the gate; but, however, after all it turned out that it was nothing else but the rather numerous flowers of Tritoma, which does very well in front of the houses there. English names may be very well outside, but inside a botanic garden does not seem at present to be the place to look for them; the danger is that a plant may get more than one, the difficulty of discovering it by either of them is thereby increased. To give an instance: Recently the genus Funkia was duly rechristened Plaintain Lily—[Because it is not a Lily, and neither a Plantago, nor a Musa, both of which are called Plantains.—EDS.]; previous to that our American cousins had dubbed it Japan Day Lily; and still further back it had been published in English catalogues as the Japan Hyacinth, and also as Japanese Hyacinth Lily. From this it seems that the English synonym promises to be as voluminous as the botanical at times now is, and if it is necessary when publishing (cataloguing) a name to add all its *aliases*, the latter will not be the least important part.

ONE of the processes for preserving the natural colour of flowers consists, says *La Belgique Horticole*, in enclosing the flower or flowers in a glass jar provided with an air-tight, hollow, ground-glass stopper, the cavity of which is filled with quick-lime wrapped in leather. The object of lime is to absorb the small quantity of humidity already existing in the jar, or which might enter on the removal of the stopper. The dry air, deprived of its carbonic acid, occupying the jar seems to brighten the colour of the flowers, and preserve them in their natural colours.

Mr. Cornelis's other method consists in burying the flowers carefully in sand and then drying them. The most convenient receptacle that he finds for this purpose is a piece of paper wrapped in the form of a cone, the point being bent over so as to form a truncated cone. The desiccation may be effected at a temperature of 90° to 100°, but the method which gives the best results is desiccation in a vacuum in the presence of commercial sulphuric acid, or any other substance which absorbs water with avidity, such, for instance, as chloride of calcium or caustic potash. The flower once dried, which will be in eight or ten days, it must be removed from the sand with great care, for it is very fragile. The dust remaining on the petals is removed by allowing coarse sand to fall upon them from a small height. After this species of washing, the specimen has received all the treatment necessary, and in this state may be preserved indefinitely if it be enclosed in a hermetically-sealed jar along with a little quicklime.

The preservation of colour in dried flowers, however, will not in all cases be attended with success, the action of light upon them being very variable. Certain kinds stand the light perfectly —even the direct light of the sun; others are even influenced by a diffused light, and there are some again that are discoloured even in partial darkness. Three plants, *Abutilon selowi*, *Fritillaria imperialis*, and *Vanda suavis*, exhibit an unlooked-for phenomenon. When dried, these flowers become of a reddish-brown, but when they are exposed to the sun they assume a tint which is quite like their original one, except *Fritillaria* (the crown-imperial), which becomes violet.

A CURIOUS modification of the normal structure of plant stems has been observed by M. Prillieux on making the temperature of the ground about the plant higher than that of the air above. Beans and pumpkins gave the best results. The seeds were placed in earth in a large dish, in which was inserted part of a brass rod bent at a right angle, and having a gas flame applied to its horizontal end. The chamber was moist and cold. The seeds germinated well, but on coming above ground the plants acquired a peculiar shape; they grew but little in length and became unusually thick, the latter growth involving much tension in the surface layers, so that deep rifts before long appeared (mostly transverse) and made further growth impossible. M. Prillieux found the enlargement traceable mainly to an increase, not of the number, but of the volume of cells in the interior (cells of the cortical tissue and the pith). The excessive growth of the cells occurred not only in the cell wall, but in the nucleus, which was often multiplied. The excess of temperature of the ground over the air was about 10 degs. Again, the view adopted by the older botanists that light is either without effect on germination, or has an adverse effect, fails to harmonise with some results lately arrived at by Herr Stebler in the case of many seeds of agricultural importance, such as varieties of meadow grass *(poa)*, the germination of which he finds to be favoured considerably more by light than by heat. Thus, with two groups of 400 seeds each of *poa memoralis* in one experiment, there germinated in light 62 per cent., and in darkness 3 per cent. Similarly with *poa pratensis*—in light, 59 per cent.; in darkness, 7 per cent., and so on. Sunlight being a very variable force difficult of determination, experiments were further made with gaslight, and with the same result—that light favours the germination of certain seeds, especially grasses, and that these germinate either not at all, or very scantily, in darkness. The fact was verified by Herr Stebler in quite a series of seeds, *Festuca*, *Cynosurus*, *Alopecurus*, &c. In the case of seeds that germinate quickly and easily, such as clover, beans, or peas, he thinks light is probably not advantageous.

THE importance of agricultural pursuits in Ceylon is clearly shown by a recent return of the export trade of the Island Of the four principal agricultural products the following are the figures of exports for the past nine years:—

Year ending 30th September.		Coffee, cwt.	Cinnamon, lbs.	Cocoanut oil, cwts.	Coir, cwts.
1873	...	995,493	1,265,757	163,274	56 921
1874	...	617 842	1,265 844	116,199	66 769
1875	...	968,694	1,103,340	121 214	63,798
1876	...	720,427	1 520,631	194,306	59,985
1877	...	943 047	1,347,171	152,416	62,855
1878	...	620,292	1 557.478	112,825	70,828
1879	...	824,509	1,467,726	218,622	69,792
1880	...	669 614	1,870,018	316 508	69 990
1881	...	453 758	1 641,178	247,113	61,504

The importance of the cocoanut palm is seen from the large quantity of oil and coir exported. During the last year there were also exported 43,337 cwts. of *Copra*. The following table shows what is being done with new products, the figures representing the exports in lbs:—

		Cinchona.	Tea.	Cacao.
1875	...	18,731	...	...
1876	...	16,842	282	...
1877	...	56,589	1,775	...
1878	...	173,497	3,515	...
1879	...	373,511	81,595	...
1880	...	1 203,518	103,624	128
1881	...	1,207,720	277 590	479

Cinchona promises well, and will [illegible] planters for the rather heavy losses they [illegible] sustained in connection with coffee. [illegible] sure to [illegible]

the Calcutta and Bombay through line by Midnapore, Sumbulpore, and Nagpore. Until this line is opened out, the Midnapore canals are available, and are at present extensively used for locomotive purposes. The pilgrim traffic to Juggernath is estimated at 300,000 annually. The estimate for the line is Rs. 30,000 per mile, and through a level country. Where the zemindars are anxious for the line, and will not therefore throw unnecessary obstacles in the way of its construction, we believe that this estimate need not be materially exceeded. The gauge would be the metre, and the pilgrim traffic alone is calculated to give a satisfactory return.

ILLUSTRATING his remarks on Fair Trade, Mr. Baxter quoted the following consumption per head of the population of several articles of daily use. We shall quote the figures for a different purpose :

	1870.	1875.	1880.	% increase in ten years
Bacon, lb.	1·98	8·26	15·96	706
Batter, lb.	4 15	4·92	7·42	76
Cheese, lb.	3 67	5·46	5·66	53
Potatoes, lb.	2·80	16·05	31·63	1,030
Wheat, lb.	122·90	197·08	210·12	...
Rice, lb.	6·71	11·68	11·14	71
Sugar (raw), lb.	41·40	53·97	54·22	109
„ (refined), lb.	5·83	8·88	9·46	31
Tea, lb.	8 81	4·44	4·59	62
Spirits, imported & exciseable galls.	1·01	1 30	1·09	8

A glance at this will show that the people of Great Britain consume the largest quantities of those articles which it is most desirable they should consume largely. If these percentages are arranged in the order of their amount, it will be found that the greater increases are in those articles which are pure necessaries of life, while the smaller increases—small only by comparison—are in those articles which, while considered necessaries, are to some extent luxuries, such as refined sugar and cheese. It is satisfactory to find the consumption of spirits checked, and that the increase is in reality only nominal. Mr. Baxter's argument was that the free-trade policy of Great Britain admitted of the masses indulging in such articles to an extent not dreamt of in a former generation.

IN 1877 the number of jalap plants, *pomea I Purga*, in the Ootacamund gardens was 100. These were grown for ornamental, and not economic purposes. Now we learn there were 25,000 at the close of 1880. After sundry experiments,—as jalap cultivation was unknown to the experimenters—three feet by two was fixed upon as the best spacing, or 7,260 plants per acre. There is nothing special about the mode of cultivation necessary ; and with the exception of careful watering being absolutely required until the plants have made a fair start, they require only a slight hoeing and weeding now and again. The plant is propagated principally by tubers, and from what has already been done, it would appear to be a profitable undertaking. Mr. Jamieson estimates that an acre of jalap plants when in full bearing, which is after three years, will yield 1,000lbs. of jalap powder. He has already sold his produce at Rs. 2-4-5 per lb., and he puts the cost of cultivating, collecting, and drying the roots, and preparing the powder at Rs. 300, or 4 annas and 10 pies per lb. The annual profit, then, on an acre ought to be—

1,000lbs. powder at Rs. 2-4 0	...	2,250
Expenses	...	300
Net profit	Rs.	1,900

The Government of Madras, which has always been ready to encourage agricultural enterprise, is prepared to distribute tubers to such as may wish to give the industry a fair trial.

THERE is a vast amount of unutilized water-power in India. The Karakwasla water-power was advertised to let recently by the Bombay Government, we believe without finding any one to make use of it, and now we see a similar course is being followed by the Punjab Government with reference to the enormous water-power now running to waste at the falls on the Bari Doab and Western Jumna canals. After making a deduction of nearly 50 per cent. for unavoidable waste of power in converting the motion of the water into useful work, there still remains more than 25,000 horse-power available. This the Government are prepared to lease, for the first three years without payment, and afterwards at rates gradually increasing during seventeen years to a maximum of about six and-a-half annas per diem per horse-power, a rate equal to about a fourth of the cost of developing the same power by steam. Of the power available, there is at present less than one per cent. utilized, principally by the "Punjab Sugar Works Company" and the "Egerton Woollen Mills Company." The greater part of the power is available in the Gurdaspore district, in which the crops raised include, in acres, food-grains 511,000, pulses 115,000, drugs and spices 15,000, oil-seeds 22,000, fibres 26,000, sugar-cane 45,000 per annum. The falls are close together, so that if the machinery required a greater fall than is available in one place, two or several falls could be combined. Metalled roads pass near many of the falls, and a railway is about to be constructed from Umritsur to Pathankote, which will pass near most of them.

THE great use of cottonseed oil is as a substitute or adulterant for olive oil, whose place it is rapidly supplying. It is nearly impossible to detect good cottonseed oil from the best brands of olive oil by taste, smell, or any other process. This the olive growers of Italy have been unwillingly compelled to acknowledge. The usual adulteration of the olive oil is by mixing 25 per cent. of it with 75 per cent. of cottonseed oil, a fine table oil being the result. Often the cottonseed receives only a very small amount of some other oil to give it a "flavour." How much of the product of the cottonseed passes into olive oil, and is eaten with relish and delight by the epicures, it is impossible to say, but that the greater portion is so eaten is shown by the countries to which New Orleans exports this product. Of 6,000,000 gallons shipped during last season, 88 per cent. was exported to Mediterranean and French ports, and one-half of this to Italy. This is more than the entire olive oil production of France, and one-fifth that of Italy itself. It is evident that not only the people of this country, but the experienced epicures of Europe, may as well make their salads with the products of the cottonseed. It is thought that in time the prejudice now existing against cottonseed oil will be overcome, and our people, like those of Europe, take to cooking their food in oil, as the Hebrews do, instead of using lard.—*Textile Manufacturer.*

THE price of wheat in Manitoba, Canada, is 75 cents per bushel, which is equal to one dollar per maund. The price of wheat at Delhi is exactly the same as this. Yet Canadian and American wheat practically keep the Indian article out of the London market. The fact is, we have no competition in the carrying trade. The Railway companies demand more for conveying Indian wheat to the seaboard, than is charged for delivering American grain in Liverpool. India is thus hopelessly handicapped. Then, again, the freight is very much higher here than in America. We look forward to the opening of the Raepore-Vizagapatam Railway to help on this trade very materially. The railway distance is small, and Raepore can grow the cheapest wheat in India. This we do not see referred to as one object in sanctioning the construction of this line, but it will doubtless bring about a revolution in the grain trade, and for this reason we trust that the permanent way will be well made, the line constructed on the broad gauge, and all bridges built for a double line. The main object of the line is to bring grain from the rich producing lands of the Central Provinces to the north Madras littoral, and this will no doubt be a great point gained. The Indian wheat trade will never have fair play until the railways carry it at very much lower rates, and until vessels of large capacity be expressly built to carry it in bulk—vessels built more for carrying capacity than for great speed.

SOME time ago, we drew attention to the "ring" or "corner," which had been formed in Bombay, for the purpose of keeping freights up to an artificial level. The rate fixed on by the syndicate was 40 shillings per ton. After the adherence of another line, they found themselves obliged to make 60 shillings

the standard. A number of merchants set about meeting the combination by entering into an agreement with a Steam Company to run a regular line, and becoming bound to find freight for the steamers at 30 shillings. We find that this latter combination has been so successful that freights at Bombay are now as low as they have been for some time, and that there is every prospect of their falling farther. This is what might have been expected, and is exactly the fate which deserves to befall all who would benefit themselves at the cost of their neighbours in a manner subversive of all fair business. We learn from the home papers by last mail that the "cotton corner" men are likely to destroy their business entirely, as the Manchester spinners are again advocating the opening up of their river, so that vessels with cotton purchased in America may come right up to their mills. This has often been agitated before, but the spur given to the movement by the conduct of the "corner" will perhaps lend more power to the present effort.

The latest returns from China quote Patna and Benares Opium at 615½ to 617½ dollars, while Malwa new is quoted at 670 and old at 710. At the same time Persian was quoted at 560 dollars. Stocks were—

Patna	... ...	2,129
Benares	... ...	887
Malwa	... ...	679
	Total Indian	3,695
Persian	... ...	1,808
	Total ...	5,503 chests.

It will be seen from this that the value of the Persian drug is steadily improving. Taking it at 1, Patna and Benares are worth 1·103, New Malwa 1·196, and Old Malwa 1·268. The difference is therefore not so very great after all, and it behoves us to look to our manufacture, if we would retain our place in the China market.

The *Indian Amateur Rose Gardener*, which Messrs. Newman & Co. have sent us, is by the same capable hand that penned "The Indian Amateur Gardener." To all lovers of rose culture and propagation in India, written as it is specially for this country, this little manual, which consists of about ninety-six pages, should prove a very welcome handbook on the subject of which it treats. All the necessary information regarding suitable soils and manures, pruning and watering, budding, grafting, the treatment of cuttings, situations, hedges, design and grouping, together with a pretty full list of exhibition roses, and numerous miscellaneous notes, is set forth in such clear terms that amateurs, for whom the book is intended, will have little difficulty in following and practising for themselves the methods of treating this favourite among flowers. The four plates and twenty-nine woodcuts which accompany the text are a valuable addition to the book; and aid materially in rendering the directions lucid and easy to follow. The little book is very prettily got up, and not in any respect behind books issued by the better class of English publishers.

It has often been said that the Government would encourage the paper industry of India if suitable paper could be made, and that supplies are all purchased from home, because Indian paper is so inferior in quality. It is quite true that India cannot at present make that class of paper which is affected by Government officials, but it could make a paper which would be quite good enough for most practical purposes, if the official idea of the article was not so lofty. A Government servant cannot "have the honor to be" without a sheet of foolscap of the richest cream-laid paper, and an immense envelope. This ought to be changed, and if it were, India could make a paper which would suffice for a great deal of Government work. This abuse of good paper will never come to an end until the present system of "service" is abolished. Let every Government letter which is carried by the postal department be paid for at the usual rate, and it will then be seen how much each department is costing in postage and stationery; and besides, the Postal Department will then for the first time be able to make a true return of its business and earnings.

The Press Association has received from correspondents throughout the United Kingdom reports of the harvest prospects, which show that, though cereals have been greatly damaged by the recent wet weather, it is hoped that a continuance of fine weather may yet counteract the effect of the severe rain of August. In any case, however, the general produce must fall short of an average both in quantity and quality. Roots, on the whole, have been benefitted by the moisture, but potatoes in most parts of England are threatened with disease. From Ireland the reports are encouraging, the crop being among the best since 1846. The *South Wales Daily News* contains a report of harvest prospects in Wales and the West of England, from upwards of 100 of its correspondents in agricultural counties of its districts. The general result is surprisingly satisfactory. In only one district is the report altogether bad. From nearly all districts the reports show that the present fine weather has saved almost everything, and that the harvest will be much above the average of the last three years.

A summary of the agricultural returns of Great Britain for the year 1881 was issued from the Board of Trade last night. These returns are collected on the 4th of June in each year. The extent of land in Great Britain under wheat cultivation in 1881 was 2,806,057 acres against 2,909,438 in 1880, and 2,890,244 in 1879. Under barley there were 2,442,405 acres in 1881 against 2,467,441 in 1880 and 2,667,176 in 1879. Under oats there were 2,909,135 acres in 1881 against 2,796,905 in 1880 and 2,656,628 in 1879. Under potatoes there were 579,431 acres in 1881 against 550,932 in 1880 and 541,344 in 1879. The live stock returns show that there were 5,911,524 cattle in 1881 against 5,912,046 in 1880 and 5,856,356 in 1879. Of sheep and lambs, there were 24,582,154 in 1881 against 26,619,050 in 1880 and 28,157,080 in 1879. Of pigs there were 2,048,034 in 1881 against 2,000842 in 1880 and 2,091,559 in 1879.

The *Pall Mall Gazette* has started the question of the possibility of Tunisian wheat ultimately ousting the Americans from the market. There can be no doubt that wheat can be grown cheaply enough in Northern Africa, and the proximity of that region to Great Britain is advanced as a reason why freights should be cheap. Freights, however, do not depend so much on the relative distance between any two points, as on the amount of reciprocal cargo to be obtained. If a vessel has to go to Tunis in ballast for return cargo, the distance is really doubled, and to this has to be added the cost of ballast and of handling it. For this reason we find freights from the Levant to Great Britain very much higher than would seem warranted by the distance. We do not think that there will be sufficient security in Tunis for a considerable time to induce settlers to invest capital in that region, and consequently we should not anticipate any great expansion in the direction indicated.

One paragraph in the report of the Royal Botanic Garden for 1880-81 seems to us to call for remark. It is where Dr. King speaks of rheea. He says he is not sanguine as to the possibility of rheea cultivation becoming a commercial success in Bengal. We went to the garden to see the crop growing some two years ago, and we were not favorably impressed with its appearance, and when we saw it subsequently at the trials made by Dr. Collyer in Dhurrumtollah-street in March, 1880, it looked dwarfed, and had little resemblance to the same plant which we had so frequently seen cultivated in Dehra Doon. It appears to us from our inspection of the growing plant that it has been planted in land liable to inundation, and this did not give it fair play, as although it revels in water, it does not thrive in stagnant water. For this reason we think the question of the suitability or otherwise of Bengal for this industry, has not yet been authoritatively settled.

Some years ago the town of Basingstoke was paved, and not many months afterwards the pavement was observed to exhibit an unevenness which could not easily be accounted for. In a short time afterwards the mystery was explained, for some of the heaviest stones were completely lifted out of their beds by the

growth of large toadstools beneath them. One of these stones measured twenty-two inches by twenty-one, and weighed eighty-three pounds, and the resistance afforded by the mortar which held it in its place would probably be even a greater obstacle than the weight. It became necessary to repave the whole town in consequence of this re-markable disturbance. A similar incident came under our own notice of a large kitchen hearthstone which was forced up from its bed by an undergrowing fungus, and had to be relaid two or three times, until at last it reposed in peace, the old bed having been removed to the depth of six inches, and a new foundation laid.

A CORRESPONDENT writes to acontemporary :—" The coffee rop evidently intends being very late this year; I hardly notice a ripe berry. The estates for the most part look as if we were in August instead of October. As a rule, by now most estates have commenced picking, and many have a ton or so in. At present, many people have [not even put up their tables, and the berries are all green and hard, and a month at least of picking. To be sure the monotony of tint is pleasantly (?) diversified by the golden glory of leaf rust, but we somehow don't altogether admire contrast. Cinchona is looking up. The young plants are getting on famously; I believe they do not care for too much rain, so that the extraordinary lightness of this year's monsoon has not affected them badly. It is enough to make one gnash one's teeth in impotent rage over wasted years and lost opportunities, to hear of ledgeriana seed selling at Rs. 500 an ounce."

DURING the nine months ending 30th September the following were the amounts of tonnage launched from the Clyde ship-building yards :—

1874	...	... 193,400	tons.
1875	...	... 169,150	"
1876	...	... 145,922	"
1877	...	... 119,020	"
1878	...	... 174,143	"
1879	...	... 126,973	"
1880	...	... 173,230	"
1881	...	... 242,000	"

From the amount of orders on hand and vessels on the stocks there is every probability of this state of things continuing, and it is to be hoped that the insane striking which seems to follow good trade will be avoided on the present occasion.

THE *Times of India* has received a sample of jute fibre from Egypt from "an experienced correspondent," who says: "I send you a little jute fibre from jute grown in Egypt. The plants I saw cut, and the fibre stripped off six stalks before me by a machine invented by a Mr. Garwood, locomotive superintendent of the Egyptian railways. The fibre as you see it was ready in four days. The staple is, I am told, very good, and I am also told that any amount can be grown in Egypt: efforts are being made to grow it on a grand scale. Garwood's machine is one which can be carried by two men from place to place, is simple in construction, and can be made for about £10. It would be, I think, just the thing for hemp fibre on this side."

H. L. MAUD, writing from Leamington to the *Times*, says :—"It may be interesting and useful to some of your readers to know the effect of planting potatoes in the autumn instead of the spring. In October last I planted a small piece of ground in my garden nine yards square with 'Magnum Bonum' potatoes, nine inches deep in the ground. From this I have just obtained 560 lbs. of the finest potatoes for the table, and a full bushel of seed potatoes. I planted some of the same seed in the spring of this year, close by the others, and from them I have comparatively only one-fourth of the crop I have from those sown in the autumn. I have not a single bad potato. This speaks strongly in favour of autumn sowing."

THE quarterly report just issued by the Secretary of the Kansas State Board of Agriculture shows an acreage this year in winter wheat of 1,174,603 acres, a decrease of 231,254 acres. Compared with last year, the estimated yield this year is 23,152,399 bushels, or an average of nearly twelve bushels per acre. The acreage in spring wheat this year is 208,779, a decrease of 20,318 acres. The acreage in corn is 4,171,544, an increase of 617,158 acres. The acreage of oats is 338,108, a decrease of 139,697 acres. The decrease in the acreage is mostly in wheat, while there is a marked increase in corn and grasses. The acreage in cotton is 135,200 acres, an increase of 51,366 acres. There is also a large increase in flax, hemp, horses, mules, all kinds of cattle, and diary products.

A SHANGHAI paper states that Li Hung-Chang has lately presented a very remarkable memorial to the Emperor. He proposes to sanction the establishment at Hongkong of an opium monopoly. It is to be in the hands of a company with a capital of $20,000,000, which shall purchase all the opium exported to China from India, or as much of it as China may be able to consume, and then re-export it from Hongkong to other ports and places of consumption. The ostensible reason alleged by the Viceroy for this proposal is two-fold. In the first place, he says it would prove an economical measure, by enabling the Government to abolish the large number of *lekin* stations now existing all over the empire, and secondly, it would put a stop to the evasion and misappropriation of *lekin* dues which now prevails, and the large amount of smuggling that goes on.

IT is estimated that over 15 binders have been at work in the harvest fields of Great Britain, Mr. Walter A. Wood alone having 80 string-binding machines at Long Sutton, Lincoln, and all doing satisfactory work. On some farms the binder has worked through the whole harvest without giving five minutes' trouble. At a trial in August by the Long Sutton Agricultural Society, Wood's machine cut six acres of wheat in less than five hours, and did not miss tying a single sheaf at the rate of one sheaf every 2½sec., excepting at the time when the ball of twine ran short, and was replaced by another. There was, unfortunately, no competition, but the judges, Mr. J. G. Hobson and Mr. George Skelton, awarded the prize to Mr. Wood for the great ingenuity and practical value of his machine.

THE *Bombay Gazette* is glad to hear that a number of native gentlemen have been prompted by Mr. Wedderburn's article on the subject of Agricultural Banks, to take up the matter with a view to establishing such a bank, as an experiment, in a particular *taluq*. "It is proposed to make the venture a matter of private enterprise entirely, Government being asked only to afford facilities for making recoveries from defaulters. The Ahmednagar *taluq*, we believe, has been chosen as the most suitable, and a scheme is being prepared by Mr. Vishvanath Narayen Mandlik, which his Excellency the Governor has promised to take into consideration when his present tour is concluded."

IT has been proven by numerous experiments that the shorter the time between milkings the richer the milk. In one case when a cow was milked twice a day, 12 hours apart, the milk gave 12½ per cent. of cream and when milked five times a day, 17½ per cent. If, therefore, the time between the milkings varies, as commonly, the milking following closest to the previous one will give the richest milk. Cows milked at half-past six in the evening and at half-past four in the morning will be pretty sure to give the richest milk in the morning, though this is partly caused by the more undisturbed time which they have at night when unharrassed by flies, &c.

IN spite of Mr. Plimsoll's mark, which can now be prominently seen on the sides of vessels, the loss of the steamer *Clan Macduff* seems to point to something else being wanted. This vessel was not said to be overloaded, but too great a proportion of her cargo consisted of unwieldy railway iron, which made her inelastic in a heavy sea, and unable to rise quickly when ingulphed for a time by a wave. This is a fault as fatal to safety or comfort as overloading, and surely an effort might be

It is important to notice, however, that some estates hold forth promise of even large crops, and that the general aspect is decidedly better than it was last year at a corresponding period

That this improvement is largely due to the more favourable season of the current year and the condition of the trees after the rest of last year, there can be no doubt, but to this must be added the equally true statement that careful cultivation and attention have had marked effects in enabling trees to set and ripen crop to a larger extent than they would otherwise have done, as is shown by comparing more neglected coffee

SUMMARY AND CONCLUSION

1.—*Hemileia vastatrix* is a parasitic fungus, the spores of which are capable of rapid germination on the moist surface of a coffee leaf The short tubes thus produced enter the breathing pores of the leaf, and in less than a week, in favorable circumstances, begin to form a mycelium which at the end of another week or so, have done sufficient damage to the leaf to produce yellow spots. During the third week the spores are usually produced each to act as before, if sown, &c

2.—A leaf of the coffee attacked at numerous points by such germinating spores rapidly succumbs to the ravages of the mycelium and falls long before it would normally have done so not only by directly robbing the tree of food prepared by the labours of the leaf but, further, by occupying space and shortening the period of usefulness of the leaf, is too tree injured.

3.—The loss of matter and functional disturbance brought about by these continued and periodical ravages have for effect a diminished power to mature crop on the part of the coffee; and flower buds, flowers, and berries fall because the nutritive relations between the shoots leaves and flowers have become overthrown. More crop is borne as a rule, however where the trees contain more food material to support it

4.—The spores of *Hemileia* are carried by wind Whether a spore travels a long distance in one journey, or whether it is swept along in successive leaps, it may be carried from one estate or district to another. The shaking of the trees also disseminate spores, and they are driven from fallen leaves to the trees These spores, scattered on the foliage, become washed down to the lower surface, and germinate as before, provided the atmosphere, &c, be sufficiently moist.

5.—No special predisposition on the part of the coffee is required for its infection, and no other conditions are necessary to the spore than moisture and the presence of air, &c, as with any germinating seed

6.—The spores are in such countless numbers, germinate so rapidly, and some of them so easily escape the action of even the most efficacious remedies, that no good and lasting result can be obtained from external applications unless the sources of reinfection be removed No attempts to combat the disease by forcing ingredients into the tree have shown any trace of success, the mycelium cannot be attacked after it has entered the leaf

7.—Diseased leaves should be collected and destroyed, and every means possible employed to prevent the ingress of winds. Cultivation should be directed to these ends, and the pruning and manuring as far as possible arranged so that large masses of young foliage are as seldom as possible exposed as a surface of food material for the spores at those times when they are most blown about, as at the bursts of the monsoons In cases where the disease is threatening to denude the trees of leaves at the critical period when crop is ripening up, there can be little question of the use of lime, unless weightier considerations, based on the results of experience with that particular soil, forbid it.

8.—Manure can in no sense be properly looked upon as a cure for the disease. In so far as it enables a tree to clothe itself with dense foliage, the tree may be able to afford the sacrifice of a number of the leaves to the fungus; but the well-fed mycelium will in such cases produce more spores in proportion, and these may be the more readily distributed, and germinate on other leaves, and so the stock of fungus be actually increased Nevertheless, careful manuring is necessary for the production of crop without damage to the tree.

9.—The burning of fallen leaves &c, is almost universally condemned by planters as too dangerous. In cases where this cannot be done it is better to bury the leaves and prunings than to leave them tossing about. In doing this, the layers of leaves and prunings (which may be mixed with weeds) should be carefully covered with caustic lime and earth and not disturbed for several months. The suggestion that the leaves might be placed under pigs and cattle affords a less safe alternative, but even this plan is much better than leaving them to be blown about the estates. The sooner the leaves are gathered after falling, the more spores are destroyed with them.

10.—The origin of leaf-disease cannot be traced with certainty, but the evidence is so strong in favour of its having arisen from an invasion of spores out of the jungle, that this view may be considered highly probable. Once on the coffee, its spread would be very rapid, where such large unbroken areas extend. No trace of valid evidence exists for the views that the disease has been "induced by artificial manuring" or "caused by alterations in the sap of the tree," it is, beyond all doubt, the results of the action of a fungus derived from without, the spores of which were either imported into Ceylon (an improbable event) or came from the native jungles.

In conclusion, I beg to call your attention to certain important details in the following appendix.

I am, &c., H. Marshall Ward, B.A., Camb.,

Peradeniya, September 1881. Cryptogamist.

LETTER from the Director of the Royal Botanic Gardens, forwarding a third Report by Mr. Marshall Ward,—Cryptogamist. (No. 29) Royal Botanic Gardens, Peradeniya, 19th September 1881.

SIR,—I have the honour to forward to you a Third Report on Coffee Leaf Disease by Mr Marshall Ward. In this he sums up the whole results of his investigation, which has extended over more than twenty months.

1. Continuing in the steady course of direct experiment and observation, and avoiding everything in the way of conjecture or theory, the Cryptogamist has now established the main facts of the true nature of this parasitic disease beyond dispute Briefly, they are these. Leaf disease itself is purely local and in no sense constitutional; it is caused solely by the *Hemileia*, runs a short and definite course, and is so formidable from the cumulative effect of constant repetition. The whole direct damage done by the fungus to coffee is loss of leaves; other serious evils, however, and especially diminished crops, follow on from this. Cleared of many erroneous observations and inferences, the ordinary life history of *Hemileia* is now shown to be of extreme simplicity, and the necessary conditions for, and exact duration of, each stage from spore to spore again have been demonstrated with unfailing and convincing frequency. It is not too much to say that as regards the structure, circumstances and habits of *Hemileia* on the coffee leaf we are now completely informed, and probably no fungus-pest has ever before received so prolonged and continuous an examination

2. This being so I apprehend the stage to be now arrived at when remedial measures may be intelligently considered and blind empirical and haphazard experiments (so called) to be no longer justifiable We know that there is one sufficient cause of leaf-disease—the uredospore of *Hemileia vastatrix* that this is produced only by a previous one, is carried freely by the wind may retain its vitality for several weeks or months, and can germinate only in moisture. This then is a *vera causa*, and in accordance with the well-known medical aphorism, to remove this would be the true practice. Difficult and perhaps impossible as this may be under present circumstances, Mr. Ward here urges several preventive measures acting in this way, and it is, in my opinion, the one which promises the best results to the practical and inventive capacity of coffee-planters Valuable guides, also in the same direction, are found in the close relations here clearly formulated between attacks of disease and weather The portion of the report devoted to this subject deserves careful study for its obvious practical bearings, especially as to the question of the possib[illegible] the coffee tree in the most suitable condition for resisting the eff[illegible] the growth of the parasite at the seasons of its chief invasions

3. Next to removing the cause come curative measures Mr Ward has done well to insist strongly that to find an agent that will kill *Hemileia* is not the most important or indeed a difficult thing to do. But he has narrowed down the practically available chemical substances of this kind to a very few, and his experiments with them do not, in my opinion, lead one to expect that it is in this direction that the principal relief is likely to be found We may surely now well reject all notions of "cures" and specifics "Prevention is better than cure" is an old adage, and with our new vantage ground of knowledge of the extremely short period during which it is possible to get at the parasite at all, the short life of each individual *Hemileia*-plant, and the frequency and want of periodicity (in the almanac sense) in the attacks of the disease, it may well be doubted whether so much benefit is to be obtained by never-ending attempts to check each attack, as by a general combination to destroy spores and hinder their dispersion. I would particularly call attention to the experiments with lime and sulphur made by Mr. Anton at Harrow—in their careful accuracy models worthy of imitation of the mode in which such should be conducted—as illustrative of the temporary nature of the benefit obtained at so large an expense.

4. The only other course is by careful cultivation, judicious manuring, and attention to the individual trees, so to improve the coffee as to enable it to endure the disease, produce fresh leaves, and bear a larger crop, but Mr. Ward properly points out that the benefit so obtained is not due to lessening in any degree leaf disease; the parasite, indeed, is likely to be increased rather than diminished.

5. On the whole, I am convinced that the possession of this clear and connected history of the disease of the coffee-leaf in Ceylon is a great gain, and has given us a largely increased chance of dealing with its ravages.

6. As I have been requested by you to offer my opinion as to the desirability or otherwise of the Cryptogamist's appointment being continued over a third year, I have, in concert with Mr Ward himself, considered carefully the present position of the enquiry from all points of view. I may say at once that Mr Ward looks upon the present report as final in its character, and does not anticipate that any discovery of practical value would result from further work at *Hemileia*. Indeed the only point of any importance remaining unsolved is the history of the second kind of spore to which attention was called in the last report To that nothing can yet be added. From the purely scientific aspect of the enquiry, further information on this matter would doubtless be of considerable interest, but any practical bearing of the discovery of a second host-plant for the fungus is rendered unimportant, since the ordinary mode of its direct dissemination by the yellow uredospores has been so

made to remedy this by a careful system of inspection. Not only should a vessel be inspected when she is clearing for sea, but the stevedores' work should be carefully supervised.

THE India-rubber industry in Mozambique seems to be developing rapidly. In 1873 only £443 worth of India-rubber passed through the Custom House. In 1876 it reached the value of £22,198, and last year, according to figures given by Mr. Consul O'Neill, it exceeded £50,000. It would seem, however, to have reached a climax until communications with the interior are properly opened up, the careless cutting of the trees by the natives having resulted in the destruction of enormous tracts of India-rubber forest.

"THE wheat districts of Canada seem to have a bright future before them. The harvest in Manitoba, a telegram from Montreal states, is very abundant. The average yield of grain is extraordinarily high. The average of wheat per acre is twenty bushels, or ten bushels higher than the highest average ever reached in Minnesota, which is the wheat-growing State." This outturn is nearly double what we obtain in India, and the soil being virgin, may be calculated to produce a good return for a long time yet.

IN Ceylon the area under cardamoms is rapidly increasing. They can be grown from a few hundreds up to 4,000 feet, although they bear best at from 2,000 to 3,000 feet. The cultivation is very simple, and a very moderate capital is required. Should a large quantity be produced, many fear there will be fall in the price. Those who are fortunate enough at present to have an acreage of cardamoms in bearing, are reaping a rich harvest.

THE Dewan of Mysore has decided to form an Agricultural Department for Mysore, and is importing improved ploughs, water-lifts, and sugarcane mills from Cawnpore. An exhibition will shortly be held. Mr. Leonard, late proprietor of the *Bangalore Spectator*, will be appointed Secretary of the Agricultural Department.

THE Chinese agriculturists are evidently averse to the introduction of the telegraph into their heavenly empire. The first telegraph line had been laid under difficulties; the agriculturists pulled up and destroyed the posts, and troops had to be sent to protect the work while in progress.

FOR the stings of wasps, scorpions, and centipedes, a learned *pundit* at Sylhet recommends the rubbing of the part with raw onion and salt. He alleges that the pain vanishes at once. Those of our readers who are inclined to experiment with the prescription had better, perhaps, begin with the wasps.

COWS cannot be cheated into giving liberal quantities of milk. What they give is in proportion to what they get.

OFFICIAL PAPERS.

COFFEE LEAF DISEASE.

FROM MR. MARSHALL WARD'S REPORT.

From H. Marshall Ward, Esq., to the Hon. the Colonial Secretary.

SIR,—I have the honor to present you with a further report on the progress of the investigation into the life-history of *Hemileia vastatrix* which I have conducted during my stay in Ceylon.

You will see that the nature of the fungus, and its casual relations with "leaf-disease" on the coffee in the island are satisfactorily determined; and that the knowledge now to hand, together with what has been put forward in my previous reports, leaves no doubts as to the bearing of the several points established upon the general questions which have been raised.

So far as coffee is concerned, the life history and anatomy of *Hemileia vastatrix* may be considered complete. The important periods occupied by the several phases of its life-history have also been ascertained, and a considerable number of developmental periods on the part of the coffee have been resolved and brought into correlation therewith.

I have, moreover, to call your attention to the real connection between climate and leaf-disease, which is no longer to be looked upon as a vague expression; but which I have shown to be of exactly the same nature as the relations existing between any other organism and its physical environment, and comparable to the equally important dependence of coffee or any other plant upon climatic conditions.

I have attempted to place the essential details of the history of this fungus, and its true relations to the coffee, &c., in the clearest form, and have omitted no fact which throws light on the difficulties experienced in understanding so intricate a subject. Having shown that the individual fungus plant is derived from without, and injures the coffee by robbing it of food—on the manufacture of which a large expenditure of energy had been employed—by occupying valuable space on the leaves and by producing profound disturbances in the functions of the plant, I further proceed to the examination of the obvious consequences of such damage on a large scale—the falling of leaves, blossom, and crop.

The distribution of the fungus has also occupied much of my attention, and the fact that it is conveyed from place to place by wind is now established by irrefutable evidence. Other important means of distribution are fully examined below, and the facts collected remove all difficulties in understanding the wide and rapid spread of the parasite by the quickly germinating spores. I futher proceed to show what occurs on large masses of coffee, as cultivated over vast open areas in Ceylon; and you will notice that the application of the preceding knowledge to the more complex problems there presented enables one to explain facts or rather collections of facts, at first apparently difficult of explanation. One important point I would especially direct your attention towards: what is known to the planters as an attack of leaf-disease, followed by the fall of leaf, is not a simple matter, but the combined or successive effects of several generations of the fungus

Much of my time has been devoted to experimental research into the efficacy of certain substances in destroying the fungus, and the advantages and disadvantages possessed by such of these as can be employed will be indicated below It will be seen, however, that the problem of combating this disease is not a mere matter of quality of chemicals and their efficacy in killing the fungus; in any scheme for mitigating the ravages of the pest, provision must be made for removing sources of re-infection, and at the same time keeping up the strength of the coffee tree. Moreover, whatever the application to the diseased leaves, it is clear that its continued action can only be counted upon for a short time after each renewal.

I have pointed out the importance of manuring and pruning, from the point of view suggested by the above, and it seems necessary to call particular attention to the value of whatever break-winds or tracts of forest or patana, &c., may separate estates from diseased areas. That the planting of other trees on estates and among the coffee, is an important aid to the same effect will, of course, be apparent. "Leaf-disease" appears to affect different estates in different degrees on account of variations in soil, climate, and other physical peculiarities; but I would draw attention to the explanation of this. Careful cultivation and natural advantages of soil, climate, &c., enable certain estates to stand forth prominently as though "leaf-disease" did not affect them, or only to a slight extent, while poor nutrition, the ravages of insects, &c, have in other cases their effect as well as "leaf-disease"

These attendant conditions, though they may complicate the problem before the individual planter, have, of course, however no connection with the origin of the parasite which causes "leaf disease." Manure, again, can in no way be looked upon as either a cause of the disease or a cure for it; its proper action is that of a food

The question whence the fungus originated admits of no direct answer. I have, however, placed before you a strong array of facts tending to prove that *Hemileia* existed in Ceylon long before it was discovered on the cultivated coffee; if, indeed, *Hemileia vastatrix* proves identical with *Hemileia Canthii*, there can be little room for doubt that the former passed to the coffee from jungle, as I have long suspected to be the truth

A review of events during the past year shows that the expectations held by planters during the earlier months of the season, have not been fulfilled and it must be recorded with regret that the general and magnificent blossom which appeared so promising in March last, have, with few exceptions, given results far below what was expected from them Notwithstanding the favourable weather, and the rarity of the fungus at the time, a very small proportion of the flowers came to the stage of young fruit, and it is to be feared that a much smaller fraction will become ripe crop. As an illustration of this I may quote the following from the remarks of a correspondent in one of the daily papers early in the year —

"The prospects of a really good year could not have been more perfectly fulfilled from the succession of fine blossoms that came out, and apparently we had weather to set them beautifully Hope against hope has been disappointed; the greater number of these blossoms come to nothing, and then at most only gave the crop that is now showing, and that, I fear, will prove deceptive, although many estates have estimated from 25 per cent. to 50 per cent. over last year. The failure of the blossom is a mystery, for on examining the cluster that have set, and are maturing on one side of an eye on a branch, on the other side of the same eye you find blossoms have entirely failed—in fact, when fresh blossoms came out of the same eye where the clusters were, they also failed, while later blossoms on the same branch set all right. This cannot be laid down to leaf-disease, or want of manure."

completely demonstrated. The Cryptogamist does not consider that another year's sojourn in Ceylon would be profitably spent either to the Colony or to himself in this search, which would be possibly futile (since the discovery of such a plant, if it exist here, is greatly a matter of chance) or, if successful, offers so slight a probability of contributing to the main purpose of the enquiry. In this opinion I fully concur. I may add, however, that though Mr. Ward may be no longer in Ceylon next year, we may perhaps have yet the benefit of some researches on the nutrition of plant cells, commenced here in connection with coffee, but requiring for their completion work in the well equipped laboratories of Europe and facility of reference to living authorities and published memoirs. This work though not strictly any part of the leaf disease enquiry, bids fair to be of special value to the growers of our staple product.—I am, &c.,

HENRY TRIMEN,
Director, Royal Botanic Gardens.

COLONEL BEDDOME ON CINCHONA IN CEYLON.

I HAVE the honor to inform you that I have lately paid a short visit to Ceylon in connection with Chinchona.

2. ROUTE PURSUED.—I was only able to spare a fortnight, so that my visit was rather hurried; but I was able to see a good many estates at different elevations and with different soils. I also obtained much information from Dr. Trimen, who accompanied me from Perdeniya through some of the estates in Kotamale and Dimbulla as far as Nuwara Eliya, whence he was obliged to return. I afterwards visited the Government plantation and nursery at Hackgalle, estates about Nuwara Eliya, Con la. nolla and Uva Pussellawa, and returned to Peradeniya through some of the estates in the Ramboda and Pussellawa Districts.

3. THE PATA.—I was much interested to find the "Pata de gallinazo" of Mr. Cross, the species hitherto known here as "Magnifolia," about which I have written so much, widely distributed in the island, chiefly amongst the "Succirubral" trees, between 3,000 and 5,000 feet elevation and maintaining its uniform character and strong rapid growth. This species is in Ceylon generally known as "Hybrid" though it has other names, and is sometimes called "Condaminea." Most planters appeared easily to recognize all their different individuals of it as one and the same plant, and always spoke of them as their "hybrids," but were delighted at a reaction against the hybrid theory and to think it a distinct species which could be propagated from seed, as many of them think with me that it is probably, within certain elevations, the Chinchona of the future; some planters were inclined to look upon each individual tree of this as a separate hybrid, and all distinct one from the other, though all most uniform in appearance. In one estate in Lindula, known as Agrakanda, I found that the analysis of the bark of three different trees of this "Pata" had been reported on by Mr. Howard. It was as follows:—

No.	Quinine.	Chinchonidine	Quinidine	Chinchonine.
IV	6·77	1·84	trace	trace
V	3·66	4·06	do.	do.
VII	4·08	2·84	do,	do,

4. These were all large, strong, healthy trees. No. VII, the largest was a little over 29 feet high and 2 feet in girth, breast high. I do not think correct data as to age was available, but they appeared to be not less than 10 years.

5. This analysis is most interesting, as showing what a very large percentage in quinine some of this species can give, and also as showing how variable the yield is from different individuals, which is, as far as I can see, equally the case with all the other species of the genus.

6. I found Dr. Trimen exceedingly interested in this species, and he had been cautioning the planters against the hybrid theory. I believe that he is now fully convinced that it is a perfectly distinct species and an undescribed one; and he intends, I believe, to describe and figure it in his Journal of Botany.

7. PUBESCENS.—I also saw trees of our "Pubescens" (or the downy variety of the "Pata") particularly in Pussellawa, but they do not appear so abundant as the glabrous species.

8. RED BARK.—The growth of "Succirubra" is exceedingly good in many parts that I visited, and I often saw it growing well in deserted coffee where in the soil must have terribly deteriorated. If all old deserted coffee plantations could be planted up with "Succirubra" it will be a great thing for both India and Ceylon; except at the lower elevations, however, tee "Pota" grows event better than the "Succirubra," and is the tree to plant at any rate anywhere above 4,000 feet.

9. CROWN BARK.—I was not fortunate in seeing any good "Officinalis" plantations of any age or size. I was not, however, able to go to Haputale or Uva, the two best districts, I believe, as far as soils and climate go. I saw both at Nuwara Eliya and in Condapolla, and elsewhere large plantations of "Officinalis" of very young growth, looking exceedingly healthy, (when sufficiently protected by an eastern exposure), but the soils every where much inferior to what we have on the Nilgiris, often very shallow or with a clayey subsoil which induces early decay, chiefly from canker; and the planters do not look to longevity for "Officinalis" in these soils, but they uproot at 4 or 5 years of age, and replant. We have nothing of this sort in India, and I trust it may never be necessary, but the whole conditions of soil and climate are different. We have not planted any tracts with a subsoil of impervious bly, and we have a period of drought which, I think, will turn out to be beneficial to "Officinalis" (though probably not for some other species) and antagonistic to canker; whilst in Ceylon, in addition to a very heavy monsoon, with often no sunshine for very long periods, they have rain all the year round, which induces early maturity and the too early flowering of the trees. So profitable is the Crown bark at present prices that even in face of this early maturity and early decay, the planters are making large profits. On one estate which I visited in upper Ramboda, called Frotoft, 45 acres of "Officinalis" had been up-rooted at $4\frac{1}{2}$ years of age, and the trees had yielded 25 tons of dry bark which was sold at 4s. per lb. (=£11,200), and it was said that 1s. per lb would even have paid. There is, of course, much doubt how often soils like this can be replanted; but uprooting in this case was imperative as the trees were all beginning to go out even at this early age from canker, and this is said to be generally the case, and that coppicing even cannot be resorted to, as it is generally the root canker. I was even told in several estates that whole nurseries had gone out from this cause. This must, I think, be simply the damping or rotting off of the roots of the seedlings from the use of too rich or damp soil in the beds, and the want of silver sand. On another estate called Lool Condura (in the same vicinity), which I did not visit, I heard that two crops had already been taken off by the same method of uprooting, with very favorable results financially, and that the estate had been planted up a third time. All these estates are considerably below 5,000 feet and consequently at an elevation much below what we grow "Officinalis" at, and this early decay may possibly be averted at the higher elevations about Nuwara Eliya, &c; the growth there is all very young at present. On one estate called, I think, Thallipody, not far from Nuwara Eliya, I found that the "Officinalis" trees had been shaved (Java method) before they were barely three years old. The proceeds were said to have cleared the estate of all expenditure, and the trees, small as they were, were certainly nearly all renewing their bark! In another estate in this locality I saw "Officinalis," which had been put down as close as $2\frac{1}{2} \times 2\frac{1}{2}$, growing very well. However, there is an opinion amongst some of the planters that close planting can be overdone, and so cause unhealthy growth from an early age that may not be easily rectified by subsequent thinnings; it is a question on which actual experience is much required.

10. BELTS OF TREES AS BREAK-WINDS.—Near Nuwara Eliya, I saw an "Officinalis" plantation in a high, bleak, exposed situation, which was exceedingly interesting on account of the systematic way in which belts of *Eucalyptus globulus* had been planted as a break-wind. As a chain apart throughout the plantations, single rows of these trees, each tree at 6 feet apart, had been put down at the same time as the Chinchona; they had been topped when young, and grown out with a bushy habit, and the Chinchona was growing, comparatively, exceedingly well, where there could have been nothing but most wretchedly-stunted growth without this protection. I think this plan can with great advantage be introduced into several portions of our plantations on Dodabetta and at Naduvatam and Pykara, and I would draw the attention of Chinchona planters generally to the great importance and value of these or similar break-winds, and I know of no tree that would answer better than the Blue-gums at high elevations

11. CALISAYAS.—I had no opportunity of seeing any good plantations of Calisaya such as, I believe exist in Maskeliya and other parts of the island which I had not time to visit: however, I saw some fine trees mixed with other Chinchonas and Coffee in different estates at low elevations. Considering the fine appearance and growth of one that I saw growing on the estate called Agrakanda in Lindula (about 4,000 feet), I think it probable that finer Calisaya will be grown in Ceylon than in India, and that with this species the moist climate of the island has the advantage against our droughts; but I have had very little experience with Calisaya. The analysis of this tree by Mr. Howard had given 5·64 per cent. of quinine, 1·22 of chinchonidine, ·44 of chinchonine, and only a trace of quinidine. Two miles from Nuwara Eliya, at the head of the Ramboda pass, I saw a a most remarkable plantation of what were called "hybrid Calisaya." The elevation is too high, I should think, for the species, being about 6,000 feet, and the trees are all quite shrubs, 4 to 6 feet high, densely branched from the base. The plantation is, however, looked upon as one of great value by some experienced planters. I recognised our var. Javanica, but there were quite a crowd of other forms that I have not seen in our plantations (we probably had some of them, and they have died out) and which would completely puzzle any botanist. It is quite possible that we have here only a single species, a very protean one, producing all these varieties from the same seed; but it is, I think, more likely that there are many really different species mixed, species which have not as yet been worked out by a botanist; either of these views are, I think, preferable to the hybrid theory. On the subject of classification Dr. Trimen has written the following valuable remarks (*vide* Mr. Owen's "Chinchona Planter's Manual"):—

"The genus Chinchona presents us with a very well-marked and striking instance of a clearly-defined natural group, in which the individuals composing it, instead of as usual being with more or less facility thrown into different sets marked out by clear distinctive characters, (and thus forming the 'species' of the naturalist), offer themselves as a crowd of forms closely connected in different directions, but showing only trifling

modifications of structure, of a sort usually regarded as of but little systematic value Such genera are not very uncommon, and the botanist of Europe is but too familiar with cases in *Salix* (willows), *Rubus* (blackberries), and *Rosa* (wild roses).

"This state of things is natural, and has not arisen under cultivation. In 'Chinchona' the great majority of the described forms have been found in the Andes themselves, where the genus has a range of over 2,000 miles from north to south, and at altitudes from 2,600—11,000 feet, but chiefly between 5,000 and 8,000 feet. It would appear that every district of this extensive area has its own peculiar Chinchonas, and very few species are known to range widely through it: none to occur throughout. A very similar statement might be made with regard to the fruticose *Rubi* in Europe"

12 Really careful experiments with the seed of each marked variety or species would be exceedingly interesting and would probably clear up the doubt whether they are distinct species or all forms of one very protean species; but if the latter be proved to be the case, the botanist will have a most difficult task in the classification of the genus. Analysis is all important in a plantation of this sort, if profit is to be looked to, and the same may be said of the ordinary form of Calisaya or of Javanica or any other of its forms, as it has been proved that farms apparently quite similar in every way may in some individuals be very rich in quinine, and in others have no trace of it The planter has, therefore, to be cautioned against any indiscriminate growth of Yellow barks at this stage of our knowledge, as not only is this an established fact, but we at present know little about the elevation or climate adapted for these species.

13 LEDGERIANA —Dr Trimen informs me that both he and Mr Moens of Java consider this species as quite a distinct one and not as hitherto supposed only a variety of "Calisaya," and that he has lately described it as such in his "Journal of Botany." He also pointed out to me that the flower pedicels always have a drooping habit not seen in "Calisaya," and that the flower buds want the knob-like apex characteristic of "Calisaya"

The enormous profits of the Ledgeriana plantation in Java under Mr. Moens and the visit last year of that gentleman to Ceylon, have given a great impetus to the planting of this species in Ceylon. I had not an opportunity of seeing the best or oldest grown in Ceylon, but I saw some large trees and many of young growth, and also experiments with Mr. Moens' system of grafting this species on "Succirubra." I however learnt that no analysis of this bark in Ceylon could in any way be compared with that in Java, and it is probable that the deep, rich, volcanic soil in the latter place is the real cause of the wonderful results. Mr Moens has obtained as much as 13 per cent. of pure quinine from one tree of this species, and Dr. Trimen tells me that he (Mr Moens) destroys all trees which on analysis do not give a very high yield and that he grafts from the richest on to "Succirubra," and that he has a small area of these grafts which are giving most surprising results and astonishing every one. Dr Trimen also informed me that this grafting on "Succirubra" was resorted to owing to the great difficulty of propagating on this species by cuttings; but Mr. Grant in the Ouchterlony valley (I was over his establishment lately) was most successful with cuttings under glass with bottom heat, scarcely having a failure, so I cannot, I confess, see the advantage of the grafting if cuttings can be grown easily in India, and I believe not only Mr Grant but also Captain Cox has had no difficulty in grafting process besides could hardly be resorted to for large areas. It is, however, important I think, that we should have some experiments on this plan when we open ground for "Calisaya" and "Ledgers at a lower elevation. Mr. Moens' plan is described as follows in the Chinchona Manual above referred to:—

"This system has been largely pursued by Mr. Moens in Java for the multiplication of Ledgerianas, with great success. For a description of the method we are indebted to 'Viator' and Mr. Kay Shuttleworth who visited Java, and there saw the operation performed, Succirubra being the commonest and most rapid-growing Chinchona is chosen for the stock Succirubra plants about a year old are chosen, and to economise space are stumped at a point six or eight inches above the soil. This is done just above a joint A flat cut is then made in the stem under the bark, which is not removed, sufficiently deep to make a surface large enough to allow a Ledgeriana shoot (cut through diagonally, the cut being one to one and-a-half inches long), to fit cambium to cambium to the Succirubra, the bark of the Succirubra overlying the cut being left intact. The Ledgeriana shoot must be cut just where the hard mature wood ends, and where the branch begins to be tender and succulent from the newness of its growth; it is then fitted carefully into the cut in the Succirubra stem, the flap of bark put over it, and the whole bound firmly with Berlin wool. String pulled out of an ordinary sack will do almost equally well The operation is simpler if the 'Succirubra' has a double stem, one of which is then cut off diagonally at the fork, leaving a flap of bark at the upper end of the cut; the Ledgeriana shoot is then cut so that it shall correspond in shape and size with the cut surface of the Succirubra, but a flap of bark is left hanging from its lower end. The two cut surfaces are then fitted together, the flap of Ledger bark overlying the 'Succirubra' stem, and the flap in the Succirubra overlying the ledger cutting, and thus giving a better hold to the binding. The pots which contain the grafted plants are then laid on the r sides, graft uppermost, in propagating frames, and kept until the bark begins to unite and new leaves to show, when they are placed upright The Succirubra is cut off just above the graft as soon as the plants are fairly united, and there is no fear of this further mutilation of the tree injuring the young graft the bandage being removed at the same time, Four weeks is the time that generally elapses before this can be done It has been proved that a good graft grows faster than an original Ledgeriana tree, and that the qualities of the stock never in the slightest degree affect the tree it bears.

"A skilled laborer can graft from 200 to 250 Ledger cuttings on 'Succirubra' stem every day, and the operation is therefore evidently not a very expensive one. There can be no doubt as to its advisability in all cases where individual trees of special value are to be propagated from.'

14. CRISPA —I saw abundance of what Dr. Trimen calls the "Crispa variety of Officinalis," and it is the same as we have abundantly represented in the Dodabetta plantations, not differing from ordinary "Officinalis," except in its rather smaller leaves, and often running into the ordinary form so as not to be distinguishable

15. URITUSINGA.—I saw no "Uritusinga" in Ceylon amongst the older Crown barks, and I am unable to distinguish this variety from "Officinalis" when they are young

16. HACKGALLE GOVERNMENT GARDENS.—As a Chinchona plantation, these have been utterly neglected; the older trees have almost all died out, or been cut down and the coppice not attended to; they were scarcely worth a visit; there were however numerous nurseries for seedlings of various kinds

17. GRASS LAND —I saw scarcely any grass-land planting; unlike the Nilgiris where nearly all the grass land rejoices in an open and gravelly soil, the grass land (or Patenas, as they are called in the Central Provinces, have generally a black peaty soil quite unfit for the growth of Chinchona and similar to what we have in swampy ravines only. I dare say there may be suitable grass-land soils in parts that I did not visit, but I only saw some small patches, but in those "Officinalis" was growing well where planted, but it was quite young.

18. IMPORTANCE OF ANALYSIS AND OF THE SERVICES OF A CHEMICAL ANALYSER.—My visit to Ceylon and the advantages I have had of discussing matters with Dr. Trimen, and also of hearing Mr. Moens' views through Dr. Trimen, has made me alter my opinions very much with reference to the value of analysis and I think it now all important that very great attention should be paid to this subject in our plantation' particularly with reference to "Officinalis" and the "Pata" (Magnifolia); individuals of which have been proved to differ so one from another in their yield of quinine. We should find out the individuals which give the richest yield, and propagate largely from these, and these only, both as to seed and cuttings, continuing the experiment through several generations. Though the experiments might not be altogether satisfactory at first, and though we might find that the seed and even the cuttings of the richest yielders might often give very varied results when planted on over large areas, I feel sure experiments of this sort must be in the right direction, and if persevered in, would ultimately give very good or even startling results, as with Mr. Moens, and we should then be able to distribute the very best (and only the very best) seed and rooted cuttings to the public. This however, can never be carried out satisfactorily unless we have a qualified Chemical Analyser for our plantations as well as a thoroughly practical gardener; but surely in a question of such importance, the expense should not be considered or allowed to interfere

SELECTIONS.

INDIAN WHEAT.

FROM certain official papers placed at our disposal, it is gratifying to notice the interest taken by her Majesty's Secretary of State for India in the question of wheat cultivation in this country. In forwarding to the Government of India a copy of a report on the result of the examination of 192 samples of wheat sent him, and which is "to form a supplement to the report by Dr. Forbes Watson," the Secretary of State observes to the Council of the Governor General that "it would be interesting if a report could be furnished giving some description of the nature of the soils in which the better classes of wheats indicated in these reports are grown, as well as of the system of cultivation followed. It would be desirable to know whether the best wheats are raised on irrigated or on manured land, also whether the land has been long cultivated with wheat crops, and what is the average weight of crops per acre. It has been alleged," continues the Secretary of State, "that the productive power of the soil in some parts of India has begun to fail, and it would be ascertained whether there is evidence of this in respect to the quality and quantity of the wheat crop raised." Mr. Alexander Smith's report to Doctor Royle at the India Office is dated from Cornhill Chambers, 29th October 1880, and it incloses notes of "valuation and classification of four parcels of wheat samples received from Doctor Royle, and a copy of the Mark Lane Corn Exchange Price List of 11th October 1880. Mr. Smith, a corn-factor, we take it, observes of the wheats that they are "much superior to the bulk ordinarily received from India in this market, both in point of—1st, cleanness (i.e. freedom from earth, earthy dust, weevil cutting, and admixture of other grain,) 2nd quality, and 3rd, size of berry; and this is particularly the case with 1st, the long-berried hard wheats, and 2nd, the wheats classified as resembling Australian, Oregon, Spanish and Californian." What seems to be most wanting on the part of agriculturists and wheat exporters from India, Mr. Smith says, are "care and cleaning machinery" The Indian soil, he says unhesitatingly, is capable of growing the best descriptions of wheat, India could always "command the top prices of the day for its wheat shipments,' if growers here could only secure clean seed of the proper description. No very difficult task this, we think, for securing and maintaining the character given to some of the shipments from Bombay as showing "a marked improvement in quality on that usually received from Calcutta." The Order of the Government of India is to the effect that copies of Mr. Smith's letter and of the "Supplemental Report on Indian Wheat" be forwarded to all the local Governments and Administrations, with "a request that the Government of India may be furnished with information on the points indicated in paragraphs 2 and 3 of the despatch," which are embraced in the extract from the Secretary of State's letter we have given above. Copies of the same were to be furnished to the Foreign Department for the purpose of being sent to the Chief Commissioner of Mysore, and other officers subordinate to it. The Officiating Chief Secretary to the Government of Madras forwarded this order to the Board of Revenue, requesting that information might be obtained on the points indicated in the Secretary of State's despatch to the Government of India, and the Superintendent of the Madras Government Farms thus replies to the Board's official memo.—"I can add but little to what is stated" in the Madras Board of Revenue's Official Memorandum of 11th June 1878. "The figures given regarding the amount of seed used, the yield, and prices obtained in the various districts are, I fear, valueless from the various reporters not having distinguished between *spelt* or *husk* wheat, and the *common* or *naked* wheat. A return of 500lbs, of the former per acre may represent a smaller yield than a crop yielding 85 lbs of the latter. Both of these varieties are grown in the wheat districts of South India. Spelt wheat is seldom met with decorticated in the bazaar, it usually being sold in the husk." Mr. Robertson proceeds to say that "the wheat crop of Southern India is a very insignificant one," but that the distribution of good seed from Central India might procure better results. He notices the absence of lime as a valuable agent in promoting the quality of wheat, and deplores the non-employment of bone-manure in any form in the wheat culture of Southern India Mr. Robertson goes on to describe deterioration both in quality and quantity of the wheat raised in the Kaity and other wheat districts of the Nilgiris, and quotes the authority of the Reverend Mr. Metz, who resided in the Kaity valley for nearly thirty years, to support what he says. In spite of the exertions of two Collectors of the district, the same deterioration has been observed

in the barley-crop under similar conditions." The Acting Sub-Secretary of the Government of Madras called upon Collectors who furnished the replies contained in the Board's Proceedings of 11th June 1878 for further information, and the Madras Government, in recording these proceedings, 'pending further report,' observe that "the Collectors named have not been asked for any information on para 2 of the Secretary of State's despatch." We presume they have since been called upon to supply this information.—*Madras Times.*

TEA AND COFFEE AT JOHORE.

WE would recommend all who take an interest in planting to drive over to Tanjong Putri, Johore, and make an inspection of the tea and coffee plantation of H. H the Maharaja of Johore. It will show those interested what can be done in these two products, and enable them to form some estimate of what the ordinary soil of the country in low lands is capable of producing. The plantation in question may be termed an experimental one. It is within two or three miles of the town and there are about two acres of tea and the same amount of coffee planted. The coffee is *Liberian*, and the trees are about two years old. The plants are six or eight feet high and the branches cover a circle of of about ten feet in diameter. They are one and all loaded with berries in different stages of ripeness. So covered with berries are they that it will probably be necessary to thin them, and it is somewhat surprising to learn that although the ground has been used by gambier and pepper growers no manure has been required for the coffee. The tea has been planted quite recently, and a portion of the plants have been out about one month and show a wonderful growth of young leaves, which, as is pretty generally known, produce the finest quality of tea. Various kinds of tea plants have been planted together, but the bulk of the seeds came from the Indian tea countries, though all of the plants seem equally healthy and strong. On the ground there is a shed for cooking and preparing the tea leaves. The kiln dried tea is very similar to Assam, and the same leaves sun-dried give a decoction similar to the tea used by the Chinese. In both cases the flavour is an agreeable one, and should take well in the local and home markets. The undoubted success of both tea and coffee so near our own door is truly remarkable, and leads one to anticipate a possible prosperous future for the waste lands of our island as well as Johore. Close to the plantation we have described, H. H the Maharaja has taken in hand to clear a large patch of primeval jungle of its undergrowth, leaving undisturbed the high forest trees This is intended for cocoa which has been tried to a considerable extent in the open country, but it is thought that it may do better in the shade, as there the tree itself, as well as the subsoil, will be protected from the rays of the sun. It is interesting to see the Yakouns of the jungle working away heartily—felling the smaller trees, and they seem to be well suited for the work—being muscular and active in their movements. Either residents or strangers have the opportunity of spending an agreeable day at Johore in visiting the plantations we have described, and H.H. The Maharaja, who is an enthusiastic planter, has always been kind enough to give those who take an interest in such matters all the information and assistance in his power.—*Straits Times.*

HOP-GATHERING.

TO those inclined to look on the dark side of the harvesting this year, we would recommended a visit to the southern counties, where their eyes would be gladdened by the sight of orchards gleaming with apples and plums, and hop-gardens heavily laden with full clusters of their various kinds of fruitage.

If Christians were to follow the seemingly paradoxical advise of the poet, to be.

"Thankful for all God takes away,
humbled by all He gives,"

there would be ample scope for both feelings in the two-fold aspect of the results of this year's harvest.

A few words on the hop-gathering may not be out of place at the present season. It is indeed, a busy time, and one much looked forward to by "young men and maidens, old men and children," to say nothing of the hard-worked mothers, who may be seen in the early morning trudging along with their families, each member who can carrying something for the day's outing. The cottages are locked up; not a soul stays behind.

Let us follow them into one of the gardens, which belongs to a respectable farmer, who prefers choosing his pickers from the parishioners and not engaging "them furriners," under which appellation are classed all outsiders, whether Irish, or those from "the s ieres," or "the Londoners"

And, first, we are struck by the extreme quietness of the field. Hardly a sound is heard. Now and then a baby cries, and there is sometimes a low hum of voices in talk at the different bins. At intervals the song of birds is twittered—and there is cackling of cocks and hens—and an occasional cry of "Poles," when the pole-puller is required to cut the stems of the hop-plants, pull up the poles, and place them near the several bins, which consist of long bags of sacking fastened on to wooden frames. There is also an absence of music, although occasionally there is a faint sound of a song somewhere. To quote the same poet, in his beautiful poem of "The Gleaners," it would be well if some of the pickers followed this advice:—

"The work with singing aid,
With ready mirth all sharper tones abate."

But if, as we have read and "heard tell," there is loud laughter, bad language, and drunken drawls at "the hopping," that conduct must be the exception, and not the rule; it certainly does not obtain in the type of hop-garden that we are describing.

The bins are placed in parallel rows; to each bin is allotted "a standard," consisting of about fifty poles on either side. When these are stripped the pickers move on to another "standard," and so the garden is by degrees shorn of its beautiful green avenues of clustering festoons, and all that remains are ordered heaps of poles, with clinging faded foliage.

At intervals the measurer comes round with a large basket measuring a bushel; he has a book, if he is "a scholar," and leaden tallies if he is "none." One book is kept at each bin by a picker to tally with that of the measurer. Great is the interest taken by the workers in noting whether the measurer is "stiff-handed"—viz., favouring the master—or "feather-handed," that is, favouring the pickers. In a good season, the price for picking "prolifics," which is a large, early hop, with scant leafage, is 1s. for eight bushels, whilst that for picking the smaller kinds, with plenty of bine, respectively called "Jonesses," "Goldings," "Colegates," and "Grape," is 1s. per six bushels. When sack after sack has been filled, they are piled on a cart, and taken off to the oast-house, where they are dried and closely packed in large sacks called "pockets" for the London market, where some kinds have fetched five guineas and more per cwt.

But now to pass on again to description. In general, the women and girls stand at their work all the day long, dressed in the oldest garments they possess, even these covered by a bibbed apron of sackcloth. On their heads are Japanese hats trimmed with white muslin, or Turkey red, which contrasts prettily with the pale green of the hops, whilst some of the women wear print sun-bonnets.

At one bin may be seen an aged grandmother perched up on a "hopping-stool," and at her side little children picking, oh! so diligently, whilst others are minding a baby under an umbrella, and others again indulging in a little play from which, however, they are inevitably called off to go on with their ant-like, or rather locust-like labours; for the multitudinous little sounds of stripping the hops recall the descriptions of the ravages of an army of locusts.

Another notable feature in the hop-garden is the presence of midges and wasps, and many a "terrified" girl would fain wield the midsummer fairy's wand, and exclaim:—

"Weaving spiders, come not here,
Hence, you long-legged spinners, hence!"

In this garden there is a bin engaged by young ladies, who are going to give their earnings to the parish church, and we find that it is by no means an unusual or Quixotic act.

It is healthy, happy work; rain and sun guarded against, even the most delicate can gain nothing but good by passing three weeks in the open air, inhaling the wholesome smell of the hops, and feeling that she is doing honest, useful work. No "fineweather pickers" these; rather the first to come and the *last* to leave, for *noblesse oblige.*

A fashionable London physician, called in to prescribe for some Belgravian maiden, with nothing serious the matter, but only jaded and faded prematurely by successive "seasons" of incessant pleasuring, might devise a worse remedy than a "season" of hop-gathering!

Let her rusticate with some of her family in a peasant house or lodgings, and join in helping her country sisters. How she would enjoy the luxury of giving earnings to some poor widow, who, perhaps, could only engage half a bin or some anxious wife or mother who has been obliged to stay at home to nurse husband or child and to forego her cherished hop-picking which was to provide bits o' things in the shape of warm clothing or boots and shoes for the on-coming winter. Many a kind and noble young heart beats under silk attire and sorely yearns to be put in the way of personally helping others.

Here is a programme of a day among lady hop-pickers:—

Rise at 6-15. Breakfast at 7. Be in the garden at 7-30, carrying their own dinner provided the day before Dine at 12 by a brook-side shaded with beech and oak, the steep Banks covered with ferns and hedge-row flowers. To work again at 1 until 5-30 or 6. Return home to tea. To bed at 9.

Not too tired, however, in the evening to resume the usual employments or accomplishments; fingers being rendered all the more "lithe and lissom" by the quick five-finger exercise of hop-picking, and in no wise marring the delicate passages of Mendelssohn or Scarlatti, and voices made all the richer for the pure air inhaled in the garden, rendering some delicious melody of Schubert or a pathetic English ballad none the worse for the long day's work.

Is the moral of our tale to be that the most fastidious of earth's daughters may go farther and fare worse than enjoy a hop-gathering in dear old England?—*Guardian.*

AGRICULTURAL SELF-HELP.

AN English reader, unfamiliar with Indian affairs, would be greatly puzzled by such a statement as that seven-tenths of the agricultural populations of a province as large as France were heavily in debt to money-lenders, and nearly one-half of them "irretrievably so." Yet this is what Sir John Strachey once upon a time affirmed in a striking Resolution on the state of the ryots in the great province over which he ruled as Lieutenant-Governor. How can a country, the vast majority of whose inhabitants is in that deplorable state, contrive to get on? Is it possible to sell up a whole population? These, and like questions, would no doubt be asked by readers familiar only with the social conditions and the legal procedures of the West. But the explanation is simple enough—too simple in fact. The Indian money-lender is in the position of a part-proprietor of the soil. He holds a perpetual lien over its produce. He transmits his claims to his descendants, and both he and they, if they cannot at any particular moment realise the full value of their legal claims, contrive in the long run to extort from their debtors rates of interest which even the money-lending touts of London would regard as magnificent. But it does not follow from this that the *sowcar* is a fiend in human shape. Even the author of the great, though still incomplete, measure for the relief of the Deccan ryots, admits that the Deccan money-lenders are by no means the race of insatiable blood-suckers they have often been represented. Improvidence on the part of borrowers is just as blameworthy as extortion on the part of lenders. Still this money-borrowing grievance constitutes a great social evil, and the worst of it is that this evil is rather intensified than weakened by our hard-and-fast systems of imported law. And many of the thinkers whom the Civil Service has produced, are of opinion that the desired amelioration in the condition of the Indian ryot can only be achieved by self-help through such means as agrarian reformers have within the last two or three generations placed within the reach of the peasantry of Germany, Denmark, Austria, and even some portions of the decaying Ottoman empire. The methods which local Governments have devised for the granting of agricultural loans are notoriously complicated and harsh in their operation. What is really required is agricultural banking by private enterprise. An experiment of this nature would no doubt be welcomed by a Viceroy whose name promises to be permanently associated with some of the most important social improvements which will distinguish our contemporary history of India.

The experience of the States to which we have referred is full of encouragement to Indian reformers. The difficulties which stood in the way of the Prussian and other statesmen who improved the condition of the cultivating classes were far more formidable than any [illegible] encountered in India. [illegible] in India no such systems of [illegible] had brought the European peasant [illegible] to the very lowest level of degradation.

The Danish landlords, for example, objected to agrarian changes because they would no longer be at liberty to flog their serfs male and female. Nor, again, is it proposed that the Indian ryots should be helped to acquire sole possession of their holdings. The idea of Indian tenure is joint ownership between the State and the cultivator, with the elimination of the classes of rent-receiving drones. But otherwise the state of the European peasant during the pre-reform period, and even now, resembles in every particular, and with the most wonderful closeness, that of the Indian ryot. Here is a passage from the report of a British Consul on agriculture in South-Eastern Europe:—"The tenant never has capital, he must therefore borrow whatever money he may need for the year's operations. Upon this money he must pay compound interest at rates varying from two to five per cent. a month, and it is always secured on his share of the coming crops. If he cannot clear off the debt in the current year, the balance due is carried, with compound monthly interest, to the next year's account which may still further run on accumulating, until it involves the wretched man in difficulties from which he despairs of ever escaping. Thus fettered, he becomes spiritless and demoralised, he labours feebly and without heart, feeling that he is the serf of a usurer, and that, however abundant the harvest, he will get from it no more than a bare subsistence." The Hon'ble Mr Hope might have described the ryots of the Mahratta country in similar terms. The means employed to remedy that state of things in Europe are—(1) loan banks for the purpose of advancing money for improvements, and (2) rent charge banks for the purpose of enabling the tenants to become proprietors in their own right within periods varying from eighteen to forty or forty-five years. The Raffeisen "agricultural loan unions of Germany, so called after the inventor of the system, the "Credit Agricole" in France, the "Caisse des Proprietaires," and "Caisse Hypothecaire" in Belgium, and the "Provincial Credit Institute" of Galicia are successful types of loan banks. The general plan is for the agricultural community of a district to become responsible for improvement loans borrowed by any of their members. The banks, on such good security, can lend at very easy rates, and receive the periodical instalments, from the district agricultural committee, who in turn collect them from the borrowers. The usual arrangement is to charge so much—say, from four to six per cent.—for interest, and an additional small percentage to form a sinking fund, so that principal and interest are both paid off after the lapse of a certain number of years. The loan banks enabled the Prussian cultivators to reclaim two millions of acres during the twenty years ending 1860. The State rendered some assistance; but five-sixths of the work was done by private enterprise.

The *modus operandi*, as regards such a country, for example as the Deccan, is very well illustrated by Mr. Wedderburn, of the Bombay Civil Service, in a small pamphlet which he recently published—"Bapu Bin Rama holds 50 acres of land, some good and some bad. He pays the Government assessment, and the expenses of cultivation, and after maintaining his family is left with a margin of profit—say Rs. 120 a year. But he owes the money-lender Rs 1,000 at two per cent. per mensem, that is, a yearly charge of Rs 240; so that he is not solvent. He struggles on, however, the balance of interest accumulating, from year to year, till becoming hopeless he relaxes his efforts, and ceases to pay anything to his creditor. The case then becomes serious for the money lender, who, under the Deccan Agriculturists Relief Act, finds it impracticable to recover against the land. He does not see his way to recover either principal or interest. So he gladly sells his claim to the Bank for cash at 8 annas in the rupee. The Bank having bought the debt for Rs. 500 recovers this amount from the cultivator by annual instalments of 12 per cent., that is, Rs 60 a month, or half his margin of profit. The cultivator thus becomes at once solvent." It is to be observed that India has the advantage over Europe as regards what we call ready-made facilities. Prussia, Denmark and Austria had to create their joint associations. But in India, joint responsibility is an immemorial fact in the village constitutions. It is obvious that, under the guarantee of a whole community perfectly familiar with his character resources, and position an Indian ryot would have greater power to execute improvements than he possibly could have on his personal security. Improved agricultural machinery, which would be too costly for one ryot and too effective for his special use, might also be introduced by associations of this sort, and turned to common use. But we may take another opportunity of entering more fully into the details of such a scheme.—*Indian Herald.*

THE SCIENCE OF AGRICULTURE.

MR. BUCKMASTER of South Kensington lately delivered a most interesting lecture on "Agricultural Scientific Education." It is now proposed in rural parishes to establish classes for teaching the science of agriculture, a subject which was added to our list three or four years ago, but which had not received very much attention. The teachers of these agricultural classes must be qualified either by passing an examination in the subject, or by the diploma of the Highland Society, or they must be graduates of some recognised University. The pupils must receive not less than twenty lessons between the examination of one year and the examination of the succeeding year and the instruction must be given according to a syllabus prepared by the professional examiner in this subject. The pupils must be instructed in the nature of soils. This is a subject on which we all need more information. It is the raw material in which the farmer has to work, and it should be a part of his business and education to study this raw material and to know all that he can know about it. The distribution and formation of soils, their classification, substances found in the ashes of plants, the sources from which these substances were obtained; active and dormant matter in the soil, conditions which regulate the conversion of dormant matter into a state available for plant food, influence of the mechanical condition of the soil on the growth of plants, good and bad management of farm-yard manure, artificial manure, phosphates, super phosphates, ammoniacal manures, nitrates, salt, chalk, lime, soot—their use and special properties, drainage of land, its influence on temperature and health of stock, rotation of crops, good courses of crops, bad courses of crops, chemical composition of the substances used as food, materials necessary for the growth of the body, maintenance of animal heat, formation of fat, muscle and bone, the economical uses of foods, mixed foods, and general rules for the preservation of health. The examination will be within the range of this course of instruction, and every qualified teacher will receive a payment of £1 or £2 for every pupil who passes the examination, and this payment comes out of the annual Parliamentary grant for education. The pupils are encouraged by prizes of books, certificates, and bursaries. Such was a general outline of the scheme for promoting the establishment of classes for teaching the science of agriculture. It may not be all that some think necessary, but faithfully carried out, it was capable of accomplishing a useful educational work in a direction not hitherto attempted, for there was nothing in the education of Scotland which had any reference to its industries. The agriculture of the future must every day become more and more thoughtful and scientific. Cheap bread and cheap meat may not be inconsistent with profitable agriculture. No one will pretend to say that he knows all that is to be known on this subject, or that the earth produces all that it is capable of producing. Agriculture, like every other civilised industry, could make but slow progress until those sciences on which the industry depends were more generally cultivated and understood. It is our increased knowledge of geology, chemistry, and physiology, which enables us to understand and explain many things which were regarded by our forefathers as unaccountable mysteries—(applause). The laws which regulate the growth of a blade of grass or the transformation of a ... into a ... are just as fixed as the law of gravity. It should be part of the education of every farmer to study these things, to try and understand them and turn them to useful purpose in his daily work. All new methods of cultivation, and every new manure have had one subject—viz., to increase the productive power of the earth and to make it bring forth more abundantly. We have largely added our national resources by the importation and manufacture of artificial manures of which our forefathers knew nothing. We have economised labour in every direction by the introduction of improved machinery. We now stand on the threshold of still greater changes, which are only to be limited by the highest intellectual effort of our nature. It is impossible to make any progress in any industrial art without a knowledge of those laws and principles upon which the art is based. To manage your land in this particular way, to grow this particular crop in succession to some other crop for no other reason than our forefathers used to do it, and they used to do it because their forefathers did it (applause)—with a creed of this kind no industry can make progress, and the higher nature of a man, instead of being quickened, must stagnate in his daily work. The progress of agriculture like that of every other industry, is a constant struggle with natural laws and natural forces. It is only by knowledge that we can subjugate these forces to our use and make them our willing subjects and slaves. Science discovers laws; art applies them. The science of an industry is for the most part a distinct thing from its practice but the most successful farmer is he who is able to unite in his daily life science with practice. There can be no such thing as two kinds of agriculture—one scientific and the other practical. All practical agriculture to be successful must be scientific, and yet there is no opinion more deeply impressed on the minds of some men than the very common belief that science and practice are opposed to each other.

WOOL vs. WHEAT.

IN the January number of this journal, under the heading of "Does the Continuous Grazing of Land with Sheep Cause it to Deteriorate in Value; Mr R. Wilkin introduces the subject of the exhaustion of soils by wool and wheat growing respectively, and invites a discussion on the subject. Since the correspondence which has taken place in *The Australasian*, however, appears to have been carried on without consideration as to the precise nature of the exhaustion which takes place in wool and wheat growing. It has been thought that it might be interesting to the readers of this journal to have the main facts bearing on this most important subject brought before them, and this paper is contributed for that purpose, with the hope that it might aid to some extent the comprehension of the problem presented by this correspondence.

Consideration will first be given to the nature of the exhaustion produced by ordinary sheep farming. Mr R. Wilkin mentions a hypothetical case of one sheep to the acre removing 10lb of material in one year, but as this would not represent the maximum exhaustion to which the soil might be subjected, but feeling at the rate of one sheep to the acre, we will take another example, and suppose a sheep to be born on an acre of soil which is to support it for the first year of its life. If at the end of this period the sheep be removed the constituent elements of its body will represent the exhaustion to which the soil has been subjected, and this will probably be the greatest amount possible at this rate of grazing, since more food constituents are assimilated during the first year of the sheep's life than in any subsequent one. Supposing when the sheep is removed at the end of the year it weighs 75lb, this weight would be approximately made up, computing our analysis on the data furnished by Messrs. Lawes and Gilbert in their classical feeding experiments, as follows:—

COMPOSITION OF BODY OF SHEEP WEIGHING 75 POUNDS.

	lb.
Nitrogenous substances	11·25
Non nitrogenous substances (fat &c.)	13 50
Mineral Matters	2 62
Water	47 63
Total	75 00

This then represents the greatest possible loss incurred by an acre of soil per annum, by sheep grazing at the rate of one sheep to the acre. The influence which this removal would have on the general fertility of the soil, when carried over longer periods depends, of course, on the general composition of the soil and on its capability of preparing plant food. Since no experiments however, appear to have been made, as far as the writer can learn, as to the ultimate effect which sheep grazing has on the soil, it will be advisable to compare the loss just mentioned to that incurred by wheat growing in which such experiments have been made.

If we take an acre of soil producing a wheat crop of 30 bushels of 60 lb. each, and disregarding the straw which we will assume to be returned again to the soil, this acre will sustain a loss of 1,800lbs. and this basing our calculations on the analysis of Dr. Emil Woolff, might be considered to be constituted as follows:

COMPOSITION OF THE GRAIN OF ONE ACRE OF WHEAT, VIZ, 30 BUSHELS OF 60 POUNDS EACH.

	lb.
Nitrogenous substances	284 0
Non-nitrogenous substances	1276 6
Ash	80 2
Water	259 2
Total	1800 0

Comparing the results of the above analysis with those of the previous one, we find that nitrogenous substances and the ash, the constituents of greatest importance as far as the soil is concerned, are removed in the following ratios:—

	Sheep.	Wheat.
Nitrogenous substances	1	... 28,8
Ash	1	... 11,6

giving a general comparative view of the two cases of exhaustion. It is not necessary here to enter into a comparison of the amounts of all the various elements which are removed in these two cases, but perhaps it might be advisable, seeing that a great deal of stress is laid by some of the writers in the correspondence before referred to, on the amount of potash removed in the fleece of the sheep to compare the amount of the constituents removed in the two cases. The amount of potash removed in a crop of wheat such as we have under consideration would be, according to Dr. B. H. Paul, about 9lb. If we assume our sheep to yield a fleece at the end of the year to the weight of 8lb., the wool would contain about 18oz. of wool soap, or suint, and this would represent about 6oz. of potash or one-twenty-fourth of that removed in the grain of the wheat crop.

In the experiments of Messrs. Lawes and Gilbert wheat has been continuously grown on the same land, without manure for between 30 and 40 years, and although the amount of produce has been gradually decreasing it has been shown that the exhaustion is mainly due to the deficiency of nitrogenous plant food.

If we consider the main portion of the herbage furnishing the sheeps feed to be composed of the grasses the drain on the food constituents of soil in wool-growing, will be similar to that of wheat, since both are gramineous plants, and require nitrogenous matter as their special food constituents. The question of exhaustion in the two cases, however, is not merely one of degree, since conditions exist is sheep grazing which are entirely absent in wheat-growing.

In sheep-grazing, the food constitutents returned to the soil in the form of excrements have a most important influence on its ultimate fertility; it is true that in the first case they are obtained from the soil, but when returned again after passing through the body of the animal, they are in such a condition that admits of their ready assimilation by plants. The excrement of sheep are richer in plant-food constituents than those of any other of our ordinary farm animals, from the fact that only 5 per cent. of the albuminoids or nitrogenous food constituents are retained by the animal as permanent increase, whereas 95 per cent. are returned to the soil to be again assimilated; and again, if we take the total food consumed by the animal in the dry condition, we shall find that it only retains twelve per cent as permanent increase. Independent of the value of the excrements due to their being in a condition admitting of ready assimilation they are also valuable from the fact that the nitrogenous portion on decomposition exerts a most beneficial action on the mineral constituents of the soil, on account of the property which it possesses of rendering certain of these, especially the phosphates, into an available condition. Although soils contain the constituents of plant food in large quantities, the question of actual quantity has not so important an influence on the subject as the amount which exists in an available form, and the capability of a soil of converting its constituents into an available condition determines its fertility. Consequently the action of excrements of the sheep would be to enrich the soil in available plant food constituents, in other words to give it increased fertility. Instances of this are well known, and several are mentioned in The *Australasian* correspondence. The only limits to this increased fertility would be the amount of the various mineral food constituents contained in the soil, whether these were in sufficient quantity to meet the demands produced by the increased luxuriance of the plants.

To render our subject somewhat more intelligible, it might be advisable to ascertain the amount of the various plant-food constituents contained in an acre of soil. An acre of soil 12in. deep has been computed to weigh 2,688,000lb., and if we calculate this amount of the analysis of one of our medium Canterbury soils, the proportion of the several constituents will be as follows:—

COMPUTATION OF THE CONSTITUENTS OF AN ACRE OF MEDIUM CANTERBURY SOIL.

	lb.
Adherent moisture	88,704
Organic matter and combined water	247,296
Silica and Insoluble matter	2,164,184
Alumina	92,736
Iron peroxide	68,276
Phosphoric anhydride	1,612
Sulphuric anhydride	1,344
Lime	4,838
Magnesia	7,796
Potash	16,396
Soda	4,838
Total	2,688 000

The above table might be taken as representing the latent resources of the soil, and the duration of the period of fertility will depend upon the amount of the various constituents present, but it is not at all probable that when exhaustion takes place, it will be general, but of only one or two of the more important constituents. Several instances of this kind of exhaustion are on record, prominent among which are the pasture land of Cheshire, which had through the constant removal of dairy produce become exhausted of their phosphates. The drain on the soil, however, in this case, is much greater than that caused by sheep-grazing. For the sake of comparison it might be mentioned as a fact that a milch cow, yielding three gallons of milk per day, would, in 14 days, remove, in the milk alone, more mineral matters than one sheep would during its lifetime.

A consideration of the foregoing remarks with regard to the mineral constituents of the soil will, it is thought, tend to show that the probabilities of their exhaustion by sheep grazing are but very small. It must also be remembered that the causes which led to the formation of soils, viz., the disintegration of rocks, are still at work, and that soils are gradually being augmented in their mineral constituents from this cause, and it remains an open question as to whether the amount so gained may not be sufficient to compensate to a large extent, the loss incurred by sheep-grazing at the rate we have mentioned.

It only remains for us now to consider the exhaustion of the nitrogenous food constituent, the one to which the exhaustion of soils by wheat is mainly due. As far as the grasses of the herbage are concerned, this nitrogenous food is the most important of any, since it is the constituent which they require mostly for their full development. The only source of nitrogen in vegetation other than that existing in the soil itself, is the small amount that is deposited from the atmosphere in rain, dew, &c. The amount obtained from this source has been estimated and found to vary according to different experimenters, from 6·68 to 10·5lb. per acre per annum. If we compare this amount with that removed by our hypothetical sheep per acre we shall find that it is more than sufficient to cover the loss incurred. In the analysis of the body of the sheep the item nitrogenous matters refers to albumenoids, which contain only about 18 per cent. of nitrogen, consequently the actual nitrogen removed would be about 2lb. per acre, or roughly, about one-fourth of that annually received from the atmosphere.

ARTIFICIAL INDIGO.

THE new dyestuffs exhibited by this firm at the recent General-German Patent and Design Exhibition may be divided into three groups: artificial indigo, naphthaline dyes, and chloraniline dyes. The first of those excites, for the moment, the greatest interest, because the discovery of the synthesis of the king of dyes is the most recent discovery in the coal tar industry, and is undoubtedly the most brilliant one since the discovery of artificial alizarine. The name of its discoverer, Prof. Bayer, which was already widely known before this, his greatest achievement, has now passed beyond the limits of his professional circle.

At the present day, discoveries in the chemistry of dyes are founded upon calculations sustained by a knowledge o chemical facts and laws. The success of experiments based upon these calculations proves or disproves their correctness. When the results are unfavorable, it is a proof of the flaws that still exist in chemical theories, in spite of their present complete development.

The synthesis of indigo could only be accomplished after an accurate knowledge of its constitution had been acquired. Many chemists have been employed in its study, but Bayer completed it. In the German patent granted him March 12, 1880, he designed the constitution of indigo in these words: "There is a certain arrangement of atoms which is peculiar to indigo and its color derivatives, and which is built up from one molecule of benzol containing a side-chain of two carbon atoms, and on this latter a nitrogen atom in the ortho position."

In his attempts to find out simple bodies whose transformation products furnished similar arrangement of atoms, he found that certain derivatives of cinnamic acid on proper treatment with chemical re-agents were able to produce the desired bodies. Formerly cinnamic acid could only be made from certain resins such as storak, tolo, and Peru balsams. Of course a technical use of this costly material for the production of so cheap a dye as indigo could never have been thought of, but cinnamic acid had already been made synthetically by the action of acetyl chloride upon benzoidehyde and more cheaply by treating chloride with acetate of soda. This chloride of benzol and the aldehyde obtained from it, are made from toluol, a hydrocarbon very abundant in coal tar. Since Bayer's discovery experiments have been undertaken on a large scale to make indigo from cinnamic acid derivative. The most important of these, and the only one now under consideration, is the orthonitrophenylpropiolic acid. In a dry state this is a yellowish white powder, and when treated with alkaline reducing agents furnishes indigo directly.

Nitrophenylpropiolic acid is best prepared as follows:

1. Cinnamic acid is nitrified with nitric acid. This produces a mixture of the ortho, meta, and para acids.

2. To separate these three acids from each other and isolate the only one that is used for making indigo, the ortho acids, they are converted into the methylic ether. This is accomplished in the usual manner with the acid of hydrochloric acid and wood spirits. The separation is effected by fractional chrystallization of the others. The most abundant companion of the ortho acid is the para acid, and a patent has been granted for its use in the manufacture of a beautiful red dye.

3. The methalic ether of this orthonitrocinnamic acid is next saponified, i. e., treated with dilute soda lye, and thus converted into methylic alcohol and the soda salt of the acid, and from this latter the acid is set free by means of ano her acid, and then dried.

4. By treatment with alkali the bromi e is abstracted along with hydrogen to form hydrobromic acid. The cinnamic acid deprived of two atoms of hydrogen, is thereby converted into a new substance, the orthonitrophenylpropiolic acid.

Of course it is necessary to recover as far as possible the expensive material, the bromic and methylic alcohol, used in its preparation. The complicate process requires a considerable outlay for apparatus and labour.

The essential factor that governs the price of the manufactured material is, of course, the yield of dye. This depends, in the first place, upon the purity of the materials used; then next upon the various processes working smoothly, and in this case, too, it depends upon whether a body is to be produced that corresponds exactly with natural indigo, or one that is homologous with it, or some substitution dyestuff.

These near relatives of indigo may, in all probability, possess the same properties as the true indigo, so that it is supposable that the production of one or other of the many bodies theoretically possible offers greater chances for its cheap production than does now the manufacture of orthonitrophenylpropiolic acid, which yields true indigo.

To explain the difficulties that attend the cheap production of this body, we need only recall a few facts, namely, how difficult it is to employ pure material on a manufacturing scale, that chemical reactions rarely run smoothly, but are generally accompanied by secondary reactions, and that it is one of the most difficult problems of scientific and practical dye-making to produce that isomere in largest quantity which is needed. So in the above process the toluol employed in making the cinnamic acid contains the higher homologues xylol and cumol, in nitrating and brominding substitution products are formed instead of addition products, etc. All these undesirable accidents necessitate expensive purifications, which stand in the way of smooth manufacture.

The expense of making artificial indigo might have proved an insuperable objection if one lucky circumstance had not come to the aid of this industry. Heretofore the cotton-printers were only able to use indigo in topical printing for dark shades at a very considerable expense, which was greatly out of proportion to the price of natural indigo, and at the same time he had great difficulties to overcome in this operation. Only a few calico printers knew how to do this, while most of them were compelled to dye the goods in the indigo vat, and then bite out the spots which were to be printed in some other color.

Any preparation suitable for printing on the goods capable of producing equally fast colors would be very welcome to the calico-printer, even if it was much more expensive than indigo. The othonitrophenypropiolic acid seems to fulfil all these conditions. It comes into the market as a 25 per cent. paste, which can be used to produce indigo directly upon the

fibre. It differs from reduced indigo—indigo—indigo white in this respect, that it forms the dye by reduction, losing an atom of oxygen while the other is converted into indigo blue again by absorption of oxygen. It is very easy to produce the deepest shades in printing with this new product, either by mixing the printing material with a suitable reducing agent, or, what is preferable, first impregnating the cotton with a reducing agent, and then printing upon it.

The color is developed in twelve to twenty-four hours spontaneously in the cold. The reducing agents employed at first were grape and milk sugar: now potassic xanthogonate is employed. The reducing agents act only in alkaline solution, but the weaker the alkali the finer the colors; hence alkaline salts, like borax are preferable.

The disadvantage of mixing the reducing agent with the printing material is that the color is developed too rapidly, and the advantages of a dye formed *in* the fibre is lost, while finished dyes cannot be fixed without albumen.

The reducing agents in use previous to xanthogenate of potash had the disadvantage that heat was necessary in developing the color. Then, too, it was difficult to ascertain the correct time and temperature, for if either was exceeded at all, the color suffered and might even be destroyed.

One disadvantage of the new product which has not yet been overcome is that the color cannot be developed by superheated steam, and hence it cannot be used along with other steam colors. It is to be hoped that this will be overcome in time by suitable reducing agents.

As remarked, indigo can be readily prepared from orthonitropropiolic acid; this can easily be converted into indigo-carmine in the usual manner. It acts just like natural indigo, but the color is handsomer than the best Bengal indigo. We have said already that the production of indigo is not yet to be thought of. But since the calico industry is able to pay a price for the new product which is proportional to the cost of its manufacture, there is abundant opportunity of collecting experiences of all sorts in its manufacture, to improve the methods, and also discover new ways of reaching the desired goal. The progress already made in this domain justifies the most brilliant expectation.—*Scientific American.*

THE DEPARTURE OF THE BIRDS.

AMONG the tokens of the waning year which just now meet the eye of the experienced observer as he makes his way through the woods or over stubble field or down is the visibly diminished numbers of our summer birds. The list of those which have left us is indeed already considerable, and many more will have vanished before the pale gold of the beeches shall have deepened into a ruddy brown. Their place, it is true, is in some degree supplied by our autumnal visitors, for the marvellous instinct which leads these creatures to change their quarters with the changes of average temperature, or rather perhaps with the varying conditions of shelter and subsistence which these changes bring about, is always active, and there is perhaps hardly a period of the year when some movement of birds is not in progress in these or more northern latitudes. We have our spring immigrants, and our autumn immigrants, and of these both in coming and departing, some are early, some late. To these are to be added the birds of passage, who, not caring to sojourn among us, yet twice a year at their appointed seasons favour us at least with that passing call which furnishes us with the proverbial expression a "flying visit." Observers of an old-fashioned class were wont to add to those certain birds which were supposed—like the tortoise or the hedgehog—to go into winter quarters—to hang themselves up in chimneys and in dark sheltered corners of old barns, there to await in dumb forgetfulness and torpor the awakening touch of Spring. Foremost among these supposed autumnal absconders was our old and dear friend the swallow, with his kith and kin; and the disappearance of the cuckoo, the nightingale, and the landrail was in like manner attributed to this imaginary habit. But though you will now and then meet even now allusions to the "hybernation" of birds, naturalists have become pretty well agreed that the swallow simply

> Flits and finds
> Whar season suiteth him; in summer droughts
> Wings northward, and in winter makes his home
> In sheltered valleys nearer to the sun.

The other alleged hybernators are in this respect pretty much of the same habit. Whether all birds come and go more or less is a question as yet undecided, but the tendency is to believe that there are few if any exceptions. Some birds, and those among the most precious in the eye of the poet and the field rambler, are, as we all know, always with us. The golden plovers that have been seen this week wheeling round in the air in great flights by Feltham and Ashford in Middlesex, and settling down thereabouts in the dusk to their meal of slugs and earthworms in the market gardens, are to be observed, for example, at most times somewhere in these islands; but it is just now that they leave the moors and find their way to such rich feeding grounds. Before long they will take wing again to hover in dark clouds about our coasts or in the great salt marshes towards the mouth of the Thames, where in wild weather their plaintive monotonous piping is a familiar sound. All that we can say even of these is that many of them remain with us all the year through. The starlings, too, who make themselves happy even in our smoky capital and may be seen at early dawn digging with their yellow bills into the turf of the enclosures of some of our inns of court, find it advisable in cold winters to get down into Devonshire and Cornwall where the moister air tempers the wintry frosts; and the vast flocks of them that are seen in these Islands in severe winters are supposed to have migrated here in search of food, to return northward in the spring. If we have a friend among the birds whose constancy is proverbial, it is assuredly the robin, who when the first touch of frost hardens the field will be emboldened to hang about our garden crofts; but even robins are apt to vanish in long-continued hard weather, save only the few that haunt our doors for crumbs, and in our shrubberies greet the red, misty winter sun with their delightful note. Though their migration has often been denied, careful observers have seen them at such time passing south, not in bands, for the redbreast is, as we all know an unsociable bird, but in pretty quick succession, manifestly departing for milder climes. Any way, the number of our redbreasts is well known to be subject to considerable variations.

The cuckoo has already been gone for some weeks; her stay among us lasts but a bare three months, and the wandering voice which comes with such welcome suggestions when leaves are young is soon hushed. The nightingales, which are rather plentiful round London, and may be heard in season in the shrubberies about the great reservoirs at Stoke Newington, where the beautiful kingfisher also haunts at scarcely three miles from the Bank, come with the cuckoo, and cease their song before the end of June. They wing southward as soon as autumn is approaching to the winter quarters on the shores of the Mediterranean, in North Africa, Egypt, or Asia Minor. The swallows may still be seen skimming the fields or ponds in many an English village, orchard or paddock. They spend six months with us, or even more, but are now just on the point of departure. In the summer season, when flies and drones and the little beetle of the scarabeus kind which they hunt so relentlessly, are plentiful, swallows may be seen all over Northern Europe—even, according to the reports of trustworthy travellers, as far towards the Pole as the inhospitable Nova Zembla, but when food begins to fail they must obey the inevitable law. The reason why his cousin the swift so generally confounded with him is the first to go must be doubtless sought in the difference of their habits. More than a month has already passed since the swift was seen skimming round our belfreys, and is now doubtless to be found in Algiers or in Tunis unless scared away by the thunder of the war. The house martin, on the other hand, lingers still, and will be seen later than the swallow, whom Gilbert White has noted as haunting the old cottages about Selborne, on one occasion as late as the fifth of November. The sand martin, who perforates the steep sides of our railway cuttings, in sandy districts near London, as at Weybridge, for example, where they swarm even within the confines of the station, is generally the earliest of the swallow tribes both to come and go, and can hardly now be met with in this country. The turtle dove, which the sportsman so often startles among the turnips in the early days of partridge-shooting, is also gone. The redbacked shrike, which the Germans call the "wurger," or strangler, and our country folk the "butcher bird," because of his cruel predatory habits, is also among the departures, so are the grasshopper warbler, the wood wren, the sedge warbler and red warbler, and the wryneck. Among those who are either gone or going are the meadow pipit, the redstart, the wheatear, the blackcap, the whinchat, the white throat, the chiff-chaff, the willow wren and the yellow wagtail. To compensate us for these losses, at least till the time shall be ripe for a further movement south, there are now beginning to arrive flights of fieldfares, missel, thrushes, redwings, woodlarks, redpoles, twites siskins, bramblies, snow buntings, and some others. But though our woods are far from having became as yet "bare, ruined choirs whereon the dead leaves hang," our birds, as we have said, have still sensibly diminished. The wintry rains of the last few weeks, and now the cold night mists, have, we fear, in not a few cases determined our feathered visitors to delay no longer.—*Daily News.*

WATERPROOFING.

WITHOUT considering the process by which cloth is waterproofed with such substances as India-rubber, oils, wax, and varnishes, there are several processes in practical use by which cloth is rendered non-absorbent of water—and for all practical purposes waterproof—without materially affecting its colour or appearance, greatly increasing its weight, or rendering it entirely airproof. These processes depend mainly upon the reaction between two or more substances, in consequence of which a substance insoluble in water is deposited in the fibres of the cloth.

The following are several of these processes:

LOWRY'S PROCESS.

Soap	2 ounces.
Glue	4 „
Water	1 gallon.

Soften the glue in cold water, and dissolve it together with the soap in the water by aid of heat and agitation.

The cloth is filled with this solution by boiling it in the liquid for several hours, the time required depending upon the kind of fibre and thickness of the cloth. When properly saturated, the excess of liquid is wrung out, and the cloth exposed to the air until (nearly dry) then digested for from five to twelve hours in the following solution:—

Alum	13 ounces.
Salt	15 „
Water	1 gallon.

It is finally wrung out, rinsed in clean water, and dried at a temperature of about 80° Fahr.

Paul's process requires a small quantity of oil, but in other respects resembles the last. It is given as follows:—

Sodium carbonate (com'l)	1 pound.
Caustic lime	½ „
Water	2½ pints.

Boil together, let it stand to settle, then draw off the clear lye, and add to it—

Tallow	1 pound.
Resin	½ „

previously melted together. Boil and stir occasionally for half-an-hour then introduce—

Glue (previously softened)	8 ounces.
Linseed oil	8 „

and continue the boiling and stirring for another half-hour.

In waterproofing one-half ounce of this soap is mixed with a gallon of hot water, and in this the goods are soaked for about twenty-four hours, according to thickness and character. The pieces are then allowed to drain until partly dried, then soaked for six hours or more in a solution prepared as follows:

Aluminium Sulphate	1 pound.
Lead acetate	½ „
Water	8 gallons.

Shake together, allow to settle, and draw off the clear liquid.

Wring out after rinsing, and dry at a temperature of 80° Fahr.

Beinvaux uses, instead of glue and oil as above, the gelatinous portion of sea-wrack grass, with a small quantity of a drying oil and common resin-soda soap.

In Reimau's process, the cloth is passed slowly by machinery through a tank divided into three compartments, the first containing a warm solution of alum, the second a warm solution of lead acetate, and the third pure water, which is constantly renewed. The cloth on passing from the latter is brushed and beaten to remove the salt adhering to the surface, and finally hot pressed and brushed. In this case, lead sulphate is deposited in the fibres.

In Townsend's process, two solutions are used as follows:

British gum	20 pounds.
Soap, White	10 „
Water	10 gallons.

The solution is boiled for some minutes, and if colour is required, one pint of logwood liquor is added. The second solution consists of a saturated solution of alum in water, or—

Zinc sulphate	6 pounds,
Water	9 gallons.

Bullard's process is somewhat similar to Reiman's. In this, strong aqueous solutions of sulphate of aluminum and lead acetate are used alternately.

Berlin waterproof cloth is said to be prepared by saturating the cloth in a solution of acetate aluminum and copper, then dipping it successively in water, glass and resin soap.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 27th October, 1881.

W. H. COGSWELL, Esq., *President*, in the Chair.

THE Proceedings of the last Monthly Meeting were read and confirmed.

The following gentlemen were elected Members :—

The Rajah of Sood, Cuttack ; Major W. Dalrymple, and Mr. C. Y. Downing.

The names of the following gentlemen were submitted for Membership :—

Col. Hicks, M. S. C., Deputy Inspector General, Police, Waltair,—proposed by Mr. H. G. Turner, M. C. S., seconded by the President.

T. C. Hill, Esq., Superintendent of Telegraphs, British Burmah Division, Rangoon,—proposed by Mr. W. Palmer, seconded by the Secretary.

Alex. Whyte, Esq., Junior, Raneegunge,—proposed by Mr. C. Dees, seconded by Mr. G. L. Kemp.

H. J. Madge, Esq., Government Surveyor of Steam Boilers,—proposed by Mr. W. H. Cogswell, seconded by Mr. J. W. O'Keefe.

Baboo Aubinash Chunder Banerjee, Zemindar, Bally,—proposed by Mr. W. Stalkartt, seconded by Baboo Peary Chand Mittra.

Rejoined—H. G. Turner, Esq., Madras Civil Service, Waltair.

CONTRIBUTIONS.

1. Report on the Government Gardens at Saharunpore and Mussoorie, for year ending March 1881. From the Superintendent.
2. The Madras Journal of Literature and Science for 1880. From the Editor.
3. Journal of the North China Branch of the Royal Asiatic Society, 1880. From the Society.
4. Journal of the Bombay Branch of the Royal Asiatic Society, 1881. From the Society.
5. Transactions of the Asiatic Society of Japan, Vol. 9, Part 2. From the Society.
6. A small quantity of Mahogany seed. From the Superintendent, Botanic Garden, Trinidad.
7. Five seers of wheat barley, From Captain J. F. Pogson.
8. A case of Araucaria plants. From J. A. Anderson, Esq.
9. A small assortment of flower seeds for the Society's Garden. From Messrs. Sutton and Sons.
10. Ten plants of *Musa textilis*, From the Government of Bengal.
11. Specimens of the wood of *Eucalyptus obliqua*, From Dr. George Henderson.

GARDEN.

A Report from the Garden Committee was submitted and adopted, alluding to a large collection of ornamental plants recently received from Mr. W. Bull, and offering certain suggestions thereon ; and recommending a few alterations in some portions of the Garden. A large number of mango and litchi grafts are now available.

DIRECTIONS FOR SOWING PITHECOLOBIUM SAMAN SEED AND FOR TREATING THE YOUNG PLANTS.

The Secretary submitted the following, received from Dr. King, Superintendent, Royal Botanic Garden :—

"The seeds of Pithecolobium saman should be sown at intervals of 2 inches apart on ground which has been previously dug to a depth of 12 inches.

"The seeds having been sown as above, ½ inch of soil should be sprinkled on them. No water should be added for three days, but watering should then be commenced, and be carried on sparingly for a week and subsequently freely. The seed will germinate within three weeks.

"When the seedlings have grown to a height of 4 or 5 inches, they should be trans planted into beds prepared as for the seed, and so situated as to secure that the young foliage be not too much exposed to the sun. The plants should be put out at intervals of 15 inches and should be freely supplied with water. Manure is quite unnecessary at any time. The plants may remain in these beds until they attain a size suitable for putting out in the sites which they are intended permanently to occupy."

CULTURE OF THE EUCALYPTUS TREE IN THE PUNJAB.

Sundry specimens of *Eucalyptus obliqua*, forwarded by Dr. George Henderson, were brought to notice, and the following communication addressed by him to the Quarter Master General in India, under date 20th September, 1881, was submitted :—

"With reference to your No. 2698, dated 9th July last, I had the honor to forward to you some days ago, samples of Eucalyptus Timber grown at Rawul Pindi, and I now send you the following opinions as to the value of this timber. I do this direct to save time, and will forward copies of the correspondence through the usual channel."

Proceedings of the Institution of Civil Engineers, Vol. 56, 1878-79, Railway Construction in Australia, page 39—

"The sleepers are of jarrah-jarrah (*Eucalyptus marginata*) imported from Western Australia which is believed to be one of the most valuable and enduring timbers in the world. It is not liable to the attack of white ants if cut at proper season, and sleepers have been taken from some of the Railways after lying in the ground for twelve years in as good a condition as when they were first laid. The sleepers are 8 feet 6 inches long, 8 inches wide and 4 inches deep, and sawn but not split from the log. The seat for the rail is adzed by machinery on the ground."

"Tredgolds Carpentery, by Hurst, page 475.—White gum, Eucalyptus obliqua—This tree is chiefly to be found in Tasmania, where it attains the height frequently of 150 feet with a diameter of nearly eight feet at about three feet from the ground. The bark of the tree is perfectly white, hence its name. The white gum is sometimes used in ship building ; but is especially valued for house-building, and for most of the purposes to which the blue gum is applied. The weight of a cubic foot and the transverse strength are about the same as those of blue gum.

"Jarrah or Australian Mahogany (Eucalyptus rostrata ?) This is also one of the gum trees which is chiefly to be found in Western Australia, where it grows to a height often exceeding 200 feet. The colour is much darker than the blue gum, and very much resembles mahogany.

"It is used for all the ordinary building purposes as well as for hydraulic works, such as piers, jetties, &c., and for ship-building.

"This timber which was employed in the whaling jetty at Freemantle was found after sixteen years to be in as good condition as when first used.

"It has a most valuable property, that of resisting the attack of the seaworm and white ant, which are said never to penetrate more than the outer or sap wood."

In 1866 I sent a specimen of Eucalyptus timber grown at Lahore to Mr. R. Bocquet, then Locomotive Superintendent, and now Agent of the Punjab and Delhi Railway.

Mr. Bocquet's report on this timber was published by me in the proceedings of the Agri-Horticultural Society for May, 1866, and is as follows :—

"Your specimen of the Eucalyptus would, I should say, make first rate timber for carriage-building purposes, especially as it attains such a magnitude. The grain is particularly close and straight, and I perceive that it is buoyant in water, which oak and sal are not."

I shall feel obliged by your submitting this letter and the samples of wood to his Excellency the Commander-in-Chief.

In a demi-official letter, Dr. Henderson adds—that almost all the trees he has at Rawul Pindi were reared from seed grown in India from plants sent to Abbottabad in 1865 and 1866 from Lahore.

Among the specimens is one of a goblet which Dr. Henderson remarks "was made from a tree of *Eucalyptus (obliqua)* which was planted by me six inches in height in March 1878, and the tree was cut March 1881, being then 22 inches in girth and 36 feet high."

NEW FRUIT FROM AFRICA.

Mr. N. Belitty sends the following extract from the proceedings of the Royal Geographical Society for July last, regarding a remarkable fruit met with by Mr. Johnson, while exploring in Central Africa, and which he thinks worthy of introduction into India :—

"Mr. Johnson mentions eating the *Suku* fruit. I too ate it, when we were short of food ; it is about as large as a small pear, only rounder with a russet rind and three large grooved stones inside. The flesh is soft and melting, more like a pear than any other European fruit. The stones each contain a small plant fully formed, and with deep green leaves which bursts its shell almost immediately that the fruit falls, which it always does as soon as it is ripe. It is an African custom to cut down a fruit tree to get at the fruit, so the *Suku* is wise, for if its fruit is on the tree, it cannot be fit to be eaten."

Letters were read—

From P. Michea, Esq., Purneah, for tobacco seed which he is cultivating on a large scale, with an experienced Curer, and promising to communicate results. Complied with.

From the Secretary, Agri-Horticultural Society, Sydney, applying for certain good varieties of sugarcane. Compliance promised when in a position to do so.

From the Secretary, Agri-Horticultural Society of Lahore, returning thanks for seeds supplied.

From the Secretary to the Agricultural Institute, Bijnore, to the same effect.

From the Superintendent, Botanical Garden, Hongkong, promising compliance as soon as possible, with request for a supply of Litchi grafts to renew garden stock.

From the Secretary, Department of Commerce and Agriculture, enquiring for the botanic name of the "Japan pea" alluded to in last month's proceedings. The Secretary mentioned he was at present unable to give this information, but had promised some of the seed when received from Japan.

Some other letters of thanks for seeds and publications and enquiries for information were submitted. For the contributions above recorded, the best thanks of the Society were accorded.

MINERALOGY.

A BALTIMORE dispatch informs us that a cartload of antimony, ten tons in all, was on the 14th of July received by C. L. Oudesluys and Co., from the southern part of Utah Territory, being the first antimony received in the east from the mines of that section. The antimony was mined about 140 miles from Salt Lake City. The ore is a sulphide, bluish gray in colour, and yields from 60 to 65 per cent. of antimony. All antimony heretofore came from Great Britain and the island of Borneo, and paid an import duty of 10 per cent. *advalorem*, and there is also some from Sonora. It is believed that with proper rail facilities to the mines of the West, there will be no need of importations.

THE quantity of petroleum now produced in Pennsylvania is something astonishing. At the present moment we learn [illegible] is one thousand million gallons [illegible] quantity may be obtained by reflecting that

at the present Calcutta rate of consumption of ten million gallons, the above quantity would supply this city for 100 years. This oil is stored in immense iron tanks, some of which had as much as 14 million gallons, and on several occasions the oil flowing from the wells was allowed to run to waste from sheer want of vessels to contain it. It is little wonder under these circumstances that kerosine oil is so cheap all over the world.

In a recent report on the mineral resources of Turkey, Consul Wrench alludes to the auriferous deposits of that country, and mentions that in some places ores have been found, some of them associated with tellurium, worth from £2,000 to £5,600 per ton, and that there is an argentiferous gold mine, situated near Sirdjiller, about 12 miles from the Dardanelles, of great value. The quartz reef constituting the mine shows itself above ground for about half a mile, is about 40ft. to 60ft. broad, and is proximate to the sea. Some specimens of quartz collected by the Consul showed no trace of gold to the naked eye, but on analysis gave from 8 oz. to 43oz. to as low as 19 dwt. of gold per ton, together with a nearly equal quantity of silver, and the reef appeared auriferous throughout.

The following, from the *Scientific American*, cannot fail to be of interest to those who use kerosine:—"Properly refined kerosine oil should be nearly colourless by transmitted light, and slightly fluorescent by reflected light: its density should be about 43° B, but the specific gravity alone is not a trustworthy test. The 'flashing point' is determined by dipping a lighted match into a small quantity of the oil; and safe oil so treated should flash under 100° F., but should extinguish the flame. The 'burning' test consists of heating a small quantity of the oil in a tin saucer in which is also placed a suitable thermometer, and noting at what temperature the oil takes fire; this should not occur under a temperature of 125° F. It is thus important to know, when kerosine is advertised as up to a test of so many degrees Fahrenheit, whether the 'flashing' or the 'burning' test is meant: for example, oil of 110° flashing test would be very good, while if the burning or igniting point was as low as that temperature it would be unsafe. Out of 736 samples of kerosine tested officially in New York, only 28 were really safe."

In view of the interest now taken in Indian mining, we may quote the silver-lead mining statistics of the United Kingdom:—

Year.		Lead Ore. Tons.	Lead. Tons.	Silver. Oz.
1876	...	79,096	58,667	483,422
1877	...	80,850	61,403	497,375
1878	...	77,850	58,020	397,471
1879	...	66,877	51,635	333,674
1880	...	72,245	56,949	295,518

A large portion of this was obtained from the lead mines in the south of Scotland. We think it was a pity that the attempt to work a mine for these minerals in Bengal should have fallen through, and it seems strange to us that the dishonesty of the agents should have interfered with a thorough and unprejudiced report being made on the mine in question, as the dishonesty of its agents need have had no connection with the value of the property. We have heard that the whole scheme was a *bogus* one, and we have also heard that the property is a valuable one. Besides we have seen good ore, said to have been taken from the mines. All these things were capable of proof or disproof, and we are surprised that this has not been seen to.

It almost seems as if we shall have to change all our ideas of geology, if the recent discovery of coal in Staffordshire turns out to be as it is reported. For many years past scientific men differed in opinion as to the probable duration of the existing coal seams, and while many and conflicting opinions are held as to the time when the supply will fail, all are agreed that it is only a question of time. It is true that other seams are available, but at such enormous depths that their existence may, for all practical purposes, be ignored, until at any rate the resources of science provide some better mode of ventilating than at present prevails. It was left for recent research to find out this Staffordshire coal field, which, it appears, lies within 18 feet of the surface. While our geologists have been busy searching for new fields in the lower depths, they have neglected this and possibly many other similar fields at the very surface. So far as yet discovered, the field is only one acre in extent, but the seam is of the amazing thickness of 42 feet. The quantity of coal therefore in this one acre amounts to 1,829,520 cubic feet, or over 100,000 tons. This is not a bad beginning, and if a few more such fields be discovered, we may look for a considerable reduction in the price of coal. A shaft will not be necessary, as the superincumbent soil will simply be removed, and the coal quarried out, the miners filling up with rubbish as they go along.

The quantity of kerosine oil imported into India has become startling in magnitude. We can well remember when such a thing was unknown in India. The great increase of late years has been caused by the extension of its use among the native portion of the community. The quantity required by the European inhabitants will not increase to any great extent, as their number is so far limited, and we must therefore look to native consumption to account for such an extensive increase of late years. In passing through the bazaar, and the native portion of the town generally, the increasing use of kerosine lamps—of a sort—cannot but strike one, and we presume the reason is that they find the oil cheaper or better than the ordinary country burning oils. Some are surprised that gas should not be more generally used by Europeans. But the fact is that kerosine oil is very much cheaper than gas. This, of course, should not be the case. We are well aware of the difficulties attending gas-making in India, so far away from the cannel coal which forms the raw material at home. Indian coal is used here, but it might be a question whether it would not pay to import home cannel coal. Allowing for freight and other charges, we suppose that gas might be provided here at a rate 63 per cent. higher than in large cities at home. In Glasgow the rate is 3s. 8d. per 1,000 cubic feet, 63 per cent. added to which would make Rs. 3. Were gas charged at this rate, it would be more commonly used. This is a question for the Gas Company, whose existence seems to be called for to supply gas for street lamps, as practically only a small percentage of private houses use gas. The imports of mineral oils for the past six years have been as follows:—

			Gallons.
1875-76	...	...	621,530
1876-77	...	...	439,123
1877-78	...	...	2,405,105
1878-79	...	...	3,775,674
1879-80	...	...	7,828,247
1880-81	...	...	10,000,026

The increase of 1880-81 over 1876-77 is at the rate of 2,177 per cent.

INDIAN KAOLINS.

(From a Correspondent.)

WILL you permit me to state, through the medium of your columns, that we have used Mangalore Kaolin and Bangalore Kaolin, at the School of Arts, and both are deficient (in common with other Indian Kaolins), in those peculiar chemical proportions necessary to produce porcelain. As several gentlemen have been good enough to send us specimens of clay, it may not be uninteresting to your readers generally, to explain the salient points connected with the manufacture of porcelain.

Kaolin, or China clay, as most people know, is a white substance, resembling chalk, and consisting of disintegrated granite, or gneiss. Its principal ingredients are alumina and silica (sand). The latter is partly free, and partly chemically combined with the alumina forming silicate of alumina. The free silica, by repeated washings, can be separated from the alumina; but the silicate of alumina, being chemically combined, cannot be chemically separated. Of the two ingredients, alumina is plastic and non-fusible; and sand non-plastic and fusible. The sand by itself could not be moulded into shape. The alumina by itself could not be fired. The office of the alumina, therefore, is to hold the particles of sand together until they melt and melting, they in their turn hold the particles of alumina together. Porcelain is the result. Now all the Indian Kaolins we have tried contain so much silicate chemically combined in the form of silicate of alumina, that they cannot be moulded into shape without the addition of common plastic clay, which is full of a fusible ingredient, causing the whole mass to melt at a temperature below that necessary to produce transparency. The result is "Wedgwood ware," the highest form of "stoneware." It seemed just possible that our potters in India lacked the skill necessary to throw the short porcelain bodies; but this point I have now settled by bringing out some of Minton's clay prepared for throwing. Our potters, I am happy to say, have thrown it just as well as the most skilful European workmen.

It is unreasonable to suppose that a country abounding in gneiss formations does not possess the finest Kaolin beds, but so far as we known they have yet to be discovered. If gentlemen willing to assist us would kindly take the trouble to treat any white substance they find according to the following directions, they would satisfy themselves as to the nature of the material discovered. Put a little of the clay in a wine glass, and pour acid on it: if it effervesces it is simply chalk. If it receives the acid as chalk would receive water, it is clay. Half-fill a large tumbler with it and then fill up with water. Work it well about, until it is of the consistency of thick soap; let it settle for a moment, and pour the contents into another tumbler. The sand will have settled in the bottom of the first; fill up with water again, agitate it and again let it settle, this time for a longer period, repeat this process five or six times, until all the free sand is separated from the clay, then let it stand for a night. In the morning pour off the clear water, strain the residuum through pocket handkerchief, knead the ball of clay resulting and ask any village potter to make a small bowl with it. If he fails to do it, the clay cannot produce a true porcelain body. It is no doubt within the resources of art by other combinations, probably hitherto unknown, to produce the sought-for article, and to this branch of the subject, we are now directing our attention; but until we have, as the basis of our operations, a careful quantitative analysis of our clay, the search would not be productive of anything more than interesting amusement to ourselves.—*Madras Mail*

THE NATRON LAKE OF LOONAR.

THERE is this very startling announcement made in the Administration Report of the Hyderabad Assigned Districts for 1879-80 just published. It is reported that the Loonar Lake, hitherto remarkable for its saline deposit, now does not retain its former productiveness, it is represented that this is due to a masonary embankment on the heights towards the villages side having given way, whereby large quantities of

mud and earth are drained into the lake annually during the rains. The strata thus formed prevent the lake from reaching the required depth so as to make it fit for depositing salt by dilution with the salt impregnated mud, and that with a view to remove this defect an estimate has been called for, for repairing the bund.

We would deprive our readers of much interesting information connected with this remarkable lake if we did not place in their hands the facts in our own possession. In 1856 Dr. George Smith, the then Residency Surgeon, who described this lake said it lies in the circar of Meihker, Sowbah of Berar. It is situated at the bottom of a cratori-form depression, which forms a singular and unexpected interruption to the general undulatory character of the District. This cratori-form shape of the hollow, if the opinion of some geologist be correct, is the crater of an extinct volcano, and the interest this will make us feel, is deepened by the fact that in all probability it is the only one in all Southern India. The action, however, even of a large crater like this must have been comparatively limited; other vents and fissures, which have left no permanent mark of their existence, must have given exit to those vast sheeted masses of porous and solid rocks constituting the trappean plateau of the Deccan. It may be also interesting to remark that at the south-east angle of the plateau, the existence of numerous hot springs seem to indicate the persistence of igneous action. But to return to our subject, this lake is almost surrounded by woods, in the thick masses of which, at the time we are writing about, were found small deserted and ruined Hindu temples, built of the common compact trap of the District. Many years ago an officer upon entering one of them was seized and severely injured by a tiger. In 1856 this lake is represented as a still sheet of water, emitting an intolerable stench of sulphuretted hydrogen especially during the heat of the day when the gas rises in millions of bubbles to the surface of the water. The lake is of green color, owing to the abundance of confervæ on portions of its surface especially near the edges. The mud close to the margins of the lake is thick black salt, and tenacious from the mixture of regur, salt and alum. When dry, fan-shaped black glassy crystals of carbonate of soda are seen. The lake at the time in question seems to have extended its bounds a good deal, as numerous dead trees were standing within its margin, and because every tree touched by this lake dies, and also by the fact that a bowrie of sweet water protected by a low wall is now completly surrounded by the water of the lake. Reptiles, fish, and insects are never found in the lake, but flocks of teal and duck dot its surface. The water has a salt and nauseous taste, and its emanations are said to give rise to fevers of intermittent and remittent types.

At two points near the centre of the lake distant from each other about half a mile nearly are two saline springs, which have never been known, even in seasons of extreme drought, to become dry. It is supposed that the muriate of soda from this source, coming in contact with the carbonate of lime found abundantly in the other springs of the lake, and in the surrounding rocks, whence it is washed down by the feeders of the lake, causes the deposition of the carbonate of soda or natron salt in a state of greater or less purity. The purest varieties, containing upwards of fifty per cent. of the neutral carbonate, being found close to the saline springs themselves, whence it is raised by diving. The depth of the lake near these springs varies from 5 or 6 feet in the hot months, to 12 or 14 during the rains.

The salt is raised by divers, who proceed towards the centre of the lake, in canoes—the divers remain under water several seconds, and come up with their hands full of salt. When the lake was very shallow in 1836 the salt was scooped up by the iron pans and towas, on which natives bake their bread. The process of raising salt was therefore rude, but the salt is much prized and finds a ready sale in both Berars, Nagpore, Candeish and Poonah. Such then was the history of the Loonar lake in 1857, and we trust that the embankment, when repaired, will tend to restore it to its former productiveness in saline deposits for the salt is useful in fixing the red dyes of cloth, and another species is used for making bangles, and for this manufacture two factories existed when each man made 6 to 700 daily; the eyesight of these men, however, fails soon owing to the entire want of protection from the glare of the glass furnace.—*Madras Athenæum.*

FORESTRY.

RECENT botanical research has shown that the trunks of trees undergo daily changes in diameter. From early morning to early afternoon there is a regular diminution till the minimum is reached, when the process is reversed, and the maximum diameter is attained at the time of twilight; then again comes a diminution, to be succeeded by an increase about dawn—an increase more marked than that in the evening. Variations in diameter are believed to coincide with the variations of tension, but they are shown to be inverse to the maximum of the temperature, the one corresponding roughly to the minimum of the other, and so on. In connection with these investigations it may be remarked that the height of a man is greater in the morning than in the afternoon, and again, that, other influences being suspended, the barometer is higher in the morning than in the afternoon.

THOUGH the agricultural capabilities of British Columbia may not be so great as other parts of Canada, its mines are doubtless very rich, and from a recent report of Professor Dawson, of the Dominion Geological Survey, its forests are of great importance. Many first-class mills have been established in various parts of the country, and the total annual product is stated to be about 200,000,000 feet, of which 25,000,000 feet is exported to other countries, 25,000,000 feet used at home, and 150,000,000 feet sent to California. Professor Dawson estimates that 110,000,000 acres (or two-thirds of the whole province) are covered with timber. The Douglas Fir, or Oregon Pine, is the most valuable commercial tree. It frequently exceeds 8 feet in diameter above the ground, and rises to to a height of from 200 to 300 feet, forming large and dark forests. The Western Hemlock and Red Cedar are the other important trees of the province, both of which, the latter especially, grow to a great size. When the great plains of Canada become populous, the mines and forests of British Columbia should be of great importance, and their produce ought to provide a large and profitable traffic for the Canadian Pacific Railway.

IN the jungles on the east coast of Cape York Peninsula much valuable timber exists, especially the highly prized red cedar (Cedrela Australis, Mueller) and bands of lumberers penetrate their gloomy recesses for the purpose of felling the trees and rafting the logs for export. It is calculated that from two of the rivers, known as the Mossman and Daintree, four million feet of cedar had been exported between November, 1874, and April, 1878, and that three million feet were at the last named date lying ready for shipment, besides another lot of half a million feet at the Johnstone river. The market value of cedar in the log is from 35s. to 40s. per 100 feet in Melbourne. The market value in Brisbane was stated at the Queensland Exhibition of 1878 to be £7 10s. to £8 10s. per 1,000 superficial feet. The value of this minor industry therefore can easily be calculated. This tree is a mere variety of the Singapore cedar (Cedrela Taona, Roxburgh), which ascends the Himalayas to 8,000 feet. It attains a height of 200 feet and the foliage is deciduous. The Rev. Dr. Woolls noted in New South Wales trees so large as to yield 30,000 superficial feet of timber. This light, beautiful wood, easily worked and susceptible of high polish, is much in request for furniture, for the manufacture of pianofortes, for boat building, and a variety of other work. The timber from the junction of the branches with the stem furnishes the choicest veneers. The bark contains a considerable quantity of tannin which produces a purplish leather.

AN ENGLISH FOREST.

THE beechnuts are already falling in the forest, and the swine are beginning to search for them while yet the harvest lingers. The nuts are formed by midsummer, and now, the husk opening, the brown angular kernel drops out. Many of the husks fall, too; others remain on the branches till next spring. Under the beeches the ground is strewn with the mast as hard almost to walk on as pebbles. Rude and uncouth as swine are in themselves, somehow they look different under trees. The brown leaves amid which they rout and the brown-tinted fern behind lend something of their colour and smooth away their ungainliness. Snorting as they work with very eagerness of appetite, they are almost wild, approaching in a measure to their ancestors, the savage boars. Under the trees the imagination plays unchecked, and calls up the past as if yew bow and broad arrow were still in the hunter's hands. So little is changed since then. The deer are here still. Sit down on the root of this oak (thinly covered with moss), and on that very spot it is quite possible a knight fresh home from the Crusades may have rested and feasted his eyes on the lovely green glades of his own unsurpassed England. The oak was there then young and strong; it is here now ancient, but sturdy. Rarely do you see an oak fall of itself. It decays to the last stump; it does not fall. The sounds are the same—the tap as a ripe acorn drops, the rustle of a leaf which comes down slowly, the quick rushes of mice playing in the fern. A movement at one side attracts the glance, and there is a squirrel darting about. There is another at the very top of the beech yonder out on the boughs, nibbling the nuts. A brown spot a long distance down the glade suddenly moves, and thereby shows itself to be a rabbit. The bellowing sound that comes now and then is from the bucks, which are preparing to fight. The swine snort, and the mast and leaves rustle as they thrust them aside. So little is changed; there are the same sounds and the same movements, just as in the olden time.

The soft autumn sunshine, shorn of summer glare, lights up with colour the fern, the grounds of which are yellow and brown, the leaves, the gray grass, and hawthorn sprays already turned. It seems as if the early morning's mists have the power of tinting leaf and fern, for so soon as they commence the green hues begin to disappear. There are swathes of fern yonder, cut down like grass or corn, the harvest of the forest. It will be used for litter and for thatching sheds. The yellow stalks—the stubble—will turn brown and wither through the winter, till the strong spring shoot comes up and the anemones flower. Though the sunbeams reach the ground here, half the green glade is in shadow, and for one step that you walk in sunlight ten are in shade. Thus partly concealed in full day, the forest always contains a mystery. The idea that there may be some hing in the dim arches held up by the round columns of the beeches lures the steps onwards. Something must have been lately in the circle under the oak where the fern and bushes remain at a distance and wall in a lawn of green. There is nothing on the grass but the upheld leaves that have dropped, no mark of any creature, but this is not decisive; if there are no physical signs, there is a feeling that the shadow is not meant. In the thickets, perhaps—the shadowy thickets with front of thorn—it has taken refuge and eluded us. Still onward the shadows lead us in vain but pleasant chase.

Those endless trees are a city to the tree-building birds. The round knot-holes in the beeches, the holes in the elms and oaks; they find them all out. From these issue the immense flocks of starlings which, when they alight on a isolated elm in winter, make it suddenly black. From these, too, come forth the tits not so welcome to the farmer, as he considers they reduce his fruit crop; and in these the gaudy woodpeckers breed. With starlings, wood-pigeons, and rooks the forest is crowded like a city in spring, but now in autumn it is comparatively deserted. The birds are away in the fields, some at the grain, others watching the plough, and following it so soon as a furrow is opened. But the stoats are busy—they have not left, nor the weasel; and so eager are they that, though they hide in the fern at first, in a minute or two they come out again, and so get shot. With all the shooting, they are not exterminated, like the marten and polecat. They are protected certainly by the burrows through which they travel, yet with so many guns against them, and the constant danger of traps it is remarkable that they do not disappear. They are friendless; even the hawks (at least the kestrel) have found special pleaders; but the stoat does not get a hand held up for him. Shot, worried by dogs, occasionally trapped, still they exist, and are not apparently much diminished in number. The destruction of the rabbits would be perhaps

the signal for their diminution, and with the rabbits the foxes would be endangered. On the other hand, the wild cats—domestic cats that have lost their homes—do not increase. Though constantly added to, they never become numerous, perhaps because they never escape shot long enough to be thoroughly acclimatised to a wild life. If the list of cats shot in the forest were kept, it would sound as if it were infested, but each of these represents a possible family destroyed. It is a little curious that, cunning and stealthy as they are, the cats do not contrive to escape and continue their kind like the stoats.

Like the fields, which can only support a certain proportion of cattle, the forest, wide as it seems, can only maintain a certain number of deer. Carrying the same thought further, it will be obvious that the forest, or England in a natural state, could only support a limited human population. Is this why the inhabitants of countries like France, where they cultivate every rood, and try to really keep a man to a rood, do not increase in number? Certainly there is a limit in nature which can only be overcome by artificial aid. After wandering for some time in a forest like this, the impression arises that the fauna is not now large enough to be in thorough keeping with the trees. Their age and size and number, the breadth of the arboreal landscape requires a longer list of living creatures and creatures of greater bulk. The stoat and weasel are lost in bramble and fern; the squirrels in the branches; the fox is concealed, and the badger; the rabbit, too, is small. There are only the deer, and there is a wide gap between them and the hares. Even the few cattle which are permitted to graze are better than nothing; though not wild, yet standing in fern to their shoulders and browsing on the lower branches, they are, at all events, animals for the time in nearly a natural state. By watching them it is apparent how well the original wild cattle agreed with the original scenery of the island. One almost regrets the marten and polecat, though both small creatures, and wishes that the fox would come forth more by day. These acres of bracken and impenetrable thickets need more inhabitants; how well they are fitted for the wild boar! Such thoughts are, of course, only thoughts, and we must be thankful that we have as many wild creatures left as we have. Looking at the soil as we walk, where it is exposed by the roots of a fallen tree, or where there is an old gravel pit, the question occurs whether forests, managed as they are in old countries, ever really increase the fertility of the earth? That decaying vegetation produces a fine mould cannot be disputed but it seems here that there is no more decaying vegetation than is required for the support of the trees themselves. The leaves that fall—the million, million leaves—blown to and fro, at last disappear, absorbed into the ground. So with quantities of the lesser twigs and branches; but these together do not supply more material to the soil than is annually abstracted by the extensive roots of trees, of bushes, and by the fern. If timber is felled it is removed, and the bark and boughs with it; the stump, too, is grubbed and split for firewood. If a tree dies it is presently sawn off and cut up for some secondary use or other. The great branches which occasionally fall are some one's perquisite. When the thickets are thinned out, the fagots are carted away, and much of the fern is also removed. How, then, can there be any accumulation of fertilizing material? Rather the reverse; it is if anything taken away and the soil must be less rich now than it was in bygone centuries. Left to itself the process would be the reverse, every tree as it fell slowly enriching the spot where it mouldered, and all the bulk of the timber converted into fertile earth. It was in that way that the American forests laid the foundation of the inexhaustible wheat lands there. But the modern management of a forest tends in the opposite direction. Nothing turns on it but the fact itself for the soil is too thin to be of any agricultural value, at least for cereal crops. It may not, however, be amiss to state that if it is wished to improve a soil by the growth of timber, something must be left in it besides the mere roots. The leaves, even, are not all left: they have a value for gardening purposes; though of course, the few cartloads collected make no appreciable difference. There is always something going on in the forests; and more men are employed than would be supposed. In the winter the selected elms are thrown and the ash poles cut; in the spring the oak timber comes down and is barked; in the autumn the fern is cut. Splitting up wood goes on nearly all the year round, so that you may always hear the axe. No charcoal burning is practised, but the mere maintenance of the fences, as, for instance, round the pheasant enclosures, gives much to do. Deer need attention in winter like cattle; the game has its watchers; and ferreting last for months. So that the forest is not altogether useless from the point of view of work. But in so many hundred acres of trees these labourers are lost to sight, and do not in the least detract from its wild appearance. Indeed, the occasional ring of the axe or the smoke rising from the woodman's fire accentuates the fact that it is a forest. The oaks keep a circle round their base and stand at a majestic distance from each other, so that the wind and the sunshine enter, and their precincts are sweet and pleasant. The elms gather together rubbing their branches in the gale till the bark is worn off and the boughs die, the shadow is deep under them and moist, favourable to rank grass and coarse mushrooms. Beneath the ashes, after the first frost, the air is full of the bitterness of their blackened leaves, which have all come down at once. By the beeches there is little underwood, and the hollows are filled ankle-deep with their leaves. From the pines comes a fragrant odour, and thus the character of each group dominates the surrounding ground. The shade is too much for many flowers, which prefer the nooks of hedgerows. If there is no scope for the use of "express" rifles, this southern forest really is a forest and not an open hillside. It a forest of trees, and there are no woodlands so beautiful and enjoyable as these, where it is possible to be lost awhile without fear of serious consequences; where you can walk without stepping up to the waist in a decayed tree-trunk, or floundering in a bog; where neither venomous snake nor torturing mosquito causes constant apprehensions and constant irritation. To the eye there is nothing but beauty; to the imagination pleasant pageants of old time; to the ear the soothing cadence of the leaves as the gentle breeze goes over. The beeches rear their Gothic architecture, the oaks are planted firm like castles, unassailable. Quick squirrels climb and dart hither and thither, deer cross the distant glade, and, occasionally, a hawk passes like thought.

The something that may be in the shadow of the thicket, the vain pleasant chase that beckons us on, still leads the footsteps from tree to tree till by and by a lark sings, and, going to look for it, we find the stubble without the forest—stubble still bright with the blue and white flowers of gray speed well. One of the earliest to bloom in the spring, it continues till the plough comes again in autumn. Now looking back from the open stubble on the high wall of trees, the touch of autumn here and there is the more visible—oaks dotted with brown, horse chestnuts yellow, maples orange, and the bushes beneath red with haws.—*Times.*

FOREST FIRES IN THE UNITED STATES.

The forest fires which have recently desolated certain sections of the United States appear, says a writer in the *Standard*, to be more than of ordinary magnitude. Over most of the settled parts of North America the timber has been cut down so recklessly that long stretches of unbroken forest-growth are getting rare in localities to the east of the Mississippi. Already the State Governments have become alarmed at the rate at which their most valuable natural crop is being destroyed, and in some cases, after it is too late, are devising measures whereby the trees, which have been so unadvisedly hewn down in places where the soil was not really required either for mining, building, or agriculture, can be re-planted. The northern parts of Michigan are, however among the few tracts which are still to some extent covered with their primeval forest. In this district little rain fell for nearly two months, and as a result fires broke out here and there, but at first they seem to have done comparatively little damage. After a few days, however, a storm of wind swept over the peninsula, carrying with it the flames, which in a few hours consumed everything in their course. The terrified settlers fled panic-stricken, trying to hide themselves in wells and caves and pits to obtain shelter. But their efforts seem to have been in vain, for, while many escaped, the latest reports represent the country as one blackened waste in several townships, scarcely a house remaining to mark the site of flourishing farms or happy homes, the crops consumed, the fences burnt up, and the owners, in too many instances, burnt alive. It is estimated that upwards of five thousand families are ruined. The dead are already known to number about two hundred, but it is believed that fully thrice as many have perished.

The great forest fires of 1881 will doubtless leave their permanent mark on the country, and, even were there no danger of another outbreak, they are certain to throw it back for many years. Such woodland fires are, of course, no new feature in the history of the United States, though of late years they have been less extensive than formerly, owing to so much of the country being cleared, and the means of controlling them having, by the increase of the population, become more abundant. They are often attributed to hunters or Indians leaving camp fires unextinguished. Undoubtedly this was, at one time, often the cause of great stretches of wood and prairie being fired, and in some cases it may be so still. The wayfarer in these wild regions is not over-anxious for what the morrow may bring forth, and to take pains to "drown out" the wood fire at which he has boiled his kettle before starting off on his morning's tramp—merely out of regard for the possible consequences—will hardly be a circumstance likely to enter his mind. However, the agency of man is not the only cause of forest fires. No sight is more familiar in a forest region, where most likely human foot has never pressed before and where there are neither Indians nor hunters, than mile after mile of country dotted with the blackened stumps which stand grim monuments of the flames that at some recent period have swept across the region. Such spots are often found in the wooded regions of the less known parts of North America. It is also a common subject of observation that flames will be seen bursting out in the woods high up on the sides of mountains where there are no hunters, and have been none for months past. These sudden fires are noticed invariably after a long continuance of hot weather, when the air is close and sulphurous, and the moss on the bark of the resinous pine and fir trees as dry as tinder. They are then ready to be ignited by a flash of lightning, or, as is quite as often the case, by the heat generated by two trees rubbing against each other.

If, as not unfrequently happens after a summer of forest fires, heavy rains fall, a conflagration of this sort is speedily drowned out. But should a high wind arise, as has been the case in Michigan, the flames might roar along on the lee of the breeze until they encounter a prairie, a lake, or some other burnt tract, when the fire will gradually die of natural exhaustion. If a party travelling on "the plains" of America see to their horror the flames of a prairie fire on the horizon behind them, their only hope of safety is to instantly rush ahead and ignite the grass in front of them, so that by the time the advancing fire in the rear overtakes them, there will be a cleared spot on which to take refuge. The most curious feature about both forest and prairie fires is that no sooner has one passed over a district than plants and trees of different species from those which formerly grew there spring up. In Vermont hickory has covered spots where before the forest was destroyed by fire, not a single tree of that species was known. The country round the head waters of the Delaware, Alleghany, and Genesee rivers, now covered with hemlock, beech, and sugar maple, was originally an oak forest; and in Georgia oak and hickory lands, when cleared, invariably grow up with pine. In the region about Green Bay, Wisconsin, overrun by the fires of 1871, dense growths of poplars and beeches succeeded the firs and deciduous trees destroyed. In the vicinity of the Slave Lake the land laid waste by fire produces nothing but poplars, in place of spruce, pine, and white birch, though none of the new trees were previously seen on the ground they now cover. In Alabama pine, under the same circumstances, is succeeded by oak; and—not to multiply examples of a curious fact—in Nebraska ash, elm, and box elder follow cotton wood, and in Florida blackjack oak, the long-leaved pine. The seeds of these trees seem to be lying dormant in the soil until stimulated into life by the passage of the flame, as was the yellow rocket, which made gay the waste places of London after the Great Fire, though the plant had previously been unknown in the district. Hence—and in a misfortune so sad it is pleasant to find some cause for satisfaction—the Michigan fire is not likely to permanently injure the land. If it has destroyed houses, fences, barns, cattle, crops, and, unhappily, their owners also, it will have aided in clearing some ground that needed clearing, and it may possibly end in giving an artificial fillip to the soil over which it has swept.—*Journal of Forestry.*

AFFORESTATION AND WATER-SUPPLY.

Voltaire's Candide tells us, '*il faut cultiver son jardin*;' and a much more ancient authority inculcates the same lesson by his censorious allusions to the condition of the garden of the sluggard. And what are the gardens of a nation but its woods and forests; and what nation of modern time, in its neglect of these sources of pleasure and wealth has not incurred the blame deservedly bestowed by moralists upon those who recklessly destroy, without attempting to replace the beneficent gifts of nature? Did not "Poor Richard", say that "the plant grows while the man sleeps," and that it is the forester's duty for every tree he fells to plant two saplings? It may be, however, questioned whether the majority of writers, from Solomon to Franklin, who have touched on this matter, viewed it in other than its merely economic aspect. They

thought, and rightly, that a tree cut down and expended was a draft on Natures bank which should be met by another deposit. The climatic effects of disafforestation was not realised in their far from perfect knowledge of physics. We believe that Humboldt was the first to indicate the control that vegetation exercises over the water-supply. In 1817, in a speech delivered before the Chamber of Deputies, Chateaubriand said: "Everywhere where trees have disappeared, man has been punished for his improvidence. I can tell you, better than any other, gentlemen, what depends upon the absence or presence of forests, because I have seen the solitudes of the New World, where Nature appears to be born, and the deserts of old Araby, where creation seems to expire. The same eloquent writer says:—"Forests precede population: deserts follow it."

A very few years ago the late talented editor of the *Japan Times*, in a series of articles on this same subject endeavoured to draw the attention of the Government of this Empire to the importance of forest conservancy and improvement. Without referring further to his essays, we can revert to his theme, the rather that nothing really complete has been done in the direction he indicated, and that the necessity of providing by plantation a check upon denudation, though evidently recognized, has yet not been encountered with vigour.

There are indeed, certain forests in Japan, the property of the State, where not only is the felling of timber restrained by very carefully devised laws, but ample provision is also made for preventing any failure in the stock of young trees. There, however, the law stops, for though districts in special localities are marked out, and the owners of woods and forests are cautioned not to cut timber there without reference to the local authorities, no penalties are provided for infringement of the prohibition, if prohibition it may be called, seeing that its observance depends upon a spontaneous recognition of its expediency. The presence or absence of a tree in these districts is in fact only considered with reference to its effect upon some bank or water-course, and not at all in connection with its sanitary influence as a living thing.

Not that the people of Japan can be charged with indifference to the state of their forests. For many and many a day it has been their habit to "reap only where they sow," or in other words to plant one, two and sometimes even as many as five saplings for every tree felled. Such at any rate is the evidence of tradition, but we are sometimes disposed to fancy that the good folk in the rural districts give themselves a little more credit than their practice warrants, for it is within our immediate knowledge that considerable districts to the north of Tokiyo have been well nigh denuded of trees during the past decade, and as for Tokiyo itself, how much remains to-day of those gloriously wooded parks, where a few years ago the pines counted their rings by hundreds and the cedars stood knee-deep in variegated bamboo-grass? The iconoclastic era that demolished all this is past indeed, but so are the "kings that flourished" before it. The days when labour and material were at the beck of every local magnate are recalled by nothing in the present, and we might almost say, that the fall of feudalism did not change the polity of Japan much more than it altered the face of the country. If we consult history we shall find that the plantation and preservation of trees was made the subject of a proclamation by the Emperor Ojin, sixteen centuries ago, and that in those days there were woodrangers in each province, whose duties were deemed sufficiently important to be controlled by no less a personage than the Emperor's son as Chief Superintendent of Forests. Four hundred years afterwards (673 A. D.) we find evidence of a similar policy in the sumptuary laws of the Emperor Temmu, and it was only from the beginning of the thirteenth to the end of the sixteenth century—the age of almost unceasing civil war—that woods and forests seem to have been left entirely to their own devices. During the Regency of the Tokugwa Princes the matter was again brought under official supervision, and the feudal barons, following the example set by their puissant chief, extended to the forests in their domains, a protection that was only possible in days when might was right.

Japan has therefore been exceptionally fortunate in this respect and yet her situation at present is not comfortable. When speaking two months ago, of the action contemplated by the Forests Bureau, we noted a fact that will bear repetition, viz., the total number of trees in Government private forests is about three thousand millions, while the number annually required for use is not much short of two hundred millions, so that Japan only possesses at present a stock of timber sufficient for from fifteen to twenty years consumption. Under these circumstances the authorities may well feel uneasy, and anything we can say in favour of energetic legislation will certainly not be amiss.

This state of affairs is not to be altogether wondered at, however much it should be regretted. Similar complaints reach us from other directions—from all the countries of America, from Australia, from India and China, in which latter lands the reckless destruction of vegetation has been responsible for the desiccation of streams, change of channels, irregularities of waterflow, floods, droughts, famines and the population. Only of late years has the requisite action been taken even in Great Britain to prevent the disappearance of timber from hill-side and fell. And now in France perhaps, the most needfully cultivated country in the world there are loud complaints that sufficient care is not taken to balance the present consumption with a thoughtful regard for the needs of the future. A study of the connection of the watersheds of Japan with the forests, and how the former have been affected within memory of those now living by the diminution of the latter would be highly interesting. It would add largely to the stock of knowledge existing on the subject generally, and could be conducted in connection with the surveys that are being constantly made for railway projection, geological, and other purposes.

The disafforestation which has been going on, to a great extent unchecked, in some parts of France, has had demonstrably disastrous consequence in the Alpine regions. Nearly forty years ago a French Engineer, M. Surell, in an *Etude sur les torrents des Hautes Alpes* demonstrated that the existence—the maintenance—of the soil of mountains depends absolutely upon the existence and maintenance of the forestral vegetation with which they are clothed. He indicated that to conserve religiously that growth in all places where it exists already and to replace it where it has disappeared, are duties devolving upon Governments. There is matter for astonishment that this maxim should be so generally recognised and so imperfectly acted upon, as pious reverence for forests, woods, and trees is discernable in the mythologies and traditions of all peoples. In old Gaul and British, the sacred groves were the sanctuaries and temples of Druidism. At the period of the Roman conquest those countries were little else than tracts of forest and, intersected by devious paths and dotted with occasional clearings. And now the clearings have quite unnecessarily, not thinned, but almost extirpated the timber. Saxon, Gaul, Norman, and French man, monarch and noble, realised and appreciated the value of wood and foliage. It remained for the manufacturing age to strip the uplands of their ornament and wealth. The damage done will have to be repaired, or present and future generations alike will suffer.

Look at central and southern France. The mighty Alps, on their swelling flanks and in their vast ravines, have present traces of the great forests whereof comparatively modern history speaks. Here and there are found the buried trunks of enormous pines, the fossil bones of old leafy dwellers on the mountain side, which to-day is bald and barren stripped naked by man or his flocks, and kept uncovered by sun and storm. In the Pyrenees so much land has been reclaimed, so much wood burned and chopped and wasted, that now there is not enough left for fuel, and whole districts have had to be abandoned through that want alone. The destruction is attributed in great part to abuse of pasturage. A certain statistician, M. Perthuis, estimates that the actual hand of man has only done about one twenty-fifth part of the damage, the balance being attributable to the teeth of his creatures. In the regions of the South the Roman laws were preserved nominally but without police. Thus the forests became communal and were delivered a prey to the rapacity and improvidence of the inhabitants. Matters were not so bad in the north where the old feudal adage, *Nulle terre sans seigneur*, obtained more rigorously; and the forests and chases were better protected than in the south where the denudation of the mountains was almost complete, and produced the most disastrous effects, deeply effects felt and bitterly regretted to-day, and from which other hilly countries would do well to learn a lesson.

Terrible inconstancy in the water-supply is the principal evil wrought by reeckless disafforestation. Mr. Surell calls the French Alps the "classic land of torrents." It is easy to trace the damage torrents have wrought in that region. Let loose by rains from the mountain summits, and unrestrained by leaf, or root, or herbage, they rush down upon the plains, carrying with them earth without cohesion, rock and rubble, flooding the valleys and annihilating the results of man's industry. Population and cultivation have disappeared in places. Comparing the records of the fifteenth and eighteenth centuries, one authority holds that in four centuries Haute Provence had lost half its cultivable soil, and fully justified the reproach of being "without land and without inhabitants." The necessity of re-wooding the denuded slopes is so apparent that strenuous efforts are already being made under Government control, and competent authorities predict with confidence their ultimate success.

Forests are better than dykes. We repeat that neglect of forest conservancy is to prepare the way for an irregular and uncontrollable water supply. A Provincial engineer at the close of the last century ascribed the formation of torrents to two causes, disafforestation and clearings, producing seven different disasters; to wit, (1) destruction of the forests; (2) annihilation of the growth of the herbage which covers the mountains (3) ruin of the estates on the banks of the rivers; (4) damage to the navigation of rivers through that alteration of channel and contour which results from strong floods; (5) law suits arising between landowners on opposite shores through the alteration of the rivers; (6) the bars which are formed at river mouths, and are a serious obstacle to navigation; (7) diminution of the springs which feed streams and rivers in their natural condition. On his part Mr. Surell propounds these four theorems from his own observation.

1.—The presence of a forest prevents the formation of torrents.
2.—Disafforestation renders the soil a prey to torrents.
3.—The development of forests tends to the extinction of torrents.
4.—The decay of forests imparts a new violence to torrents and perhaps causes them to be renewed.

Meanwhile private effort can come largely to the aid of the State. It should always be borne in mind—if we may be allowed to re-state a truism—that he who makes two blades of grass grow where one grew before is a benefactor to his contemporaries; and that he who plants an acorn may, by that act, have sown the seed of a fortune for his descendants.—*Japan weekly Mail.*

GARDEN.

KEEPING CAMELLIAS CLEAN.—The importance of keeping the foliage of camellias clean cannot be over-estimated. To have the leaves coated with smut or scale or any other insect, is simply to mar the beauty of the plants as well as to lead to disappointment in the production of the flowers. The plant should be gone over at the present time, if dirty, with a sponge or brush with soap and water, cleaning every leaf, beginning with those at the top of the plant and cleaning downwards. If they are dried afterwards with a sponge or dry cloth they will present a lustrous appearance that is both beautiful and healthful.

AZALEAS.—These should be looked over carefully just now see that they are also thoroughly clean. If they are infested with thrips, which they often are immediately after being housed for the winter, let them be attended to at once, or the result will be bare, leafless plants by and by, and a poor display of flowers. Fumigation with tobacco smoke is the best cure for thrips, which are the most common enemy of the azalea. The process should be repeated every alternate night till the insects are all killed, and each morning after fumigation they should be well syringed, letting the water be directed to the under sides of the leaves mainly. If red spider should also be present, let some tobacco water, soft soap, and, sulphur, be mixed with the water for syringing every time it is used.

SINGLE.—FLOWERED DAHLIAS.—These undoubtedly beautiful flowers are attracting much attention from flowear. They are lighter and more elegant than the older varieties, and they have, in some instances at least greater brilliancy and purity of colour than those. They can be reared and propagated by seed, and be flowered the same season, which is a great gain, thus doing away with the troublesome process of propagation by means of cuttings. If the seeds are sown in February they will flower freely in the following July August, September, and October. The seeds must be sown in brisk heat, and the plants be encouraged to progress without checks from any cause. As soon as they are large enough to handle, let them be pricked of from the seed pan or pot into small pots of say, 2 inches diameter. When they have established themselves in these—and they ou ht, not at this or any stage prior to planting out be allowed to become pot bound—give them a shift into a large sized pot. From first to last they must have the most liberal culture, and they are most worthy of it. We know nothing more satisfactory for cutting or for general decoration than these among plants capable of being cultivated in the open air in summer time. The following is a selection of the best in culture at the present time:—

Coccinea, brilliant scarlet.
Paragon, deep margon, margined purple.

White queen, pure white.
Yellow queen, fine bright yellow.
Vivid, intense scarlet.
Cervantesi, bright yellow.
Yellow beauty, golden yellow.
Gracilis, scarlet.

VALLOTA PURPUREA.

THIS is without exception one of the most beautiful of autumn or early winter flowering bulbs, and withal one of the most easy to cultivate. How purpurea happens to be applied to it as a specific name, we can form no idea, except, indeed, it be because the colour of the flowers is not purple, but good brilliant scarlet, with the least possible dash of purple in its composition. This would only be one amongst many of the examples of misleading inaccuracy in the use of botanical names which perplex the uninitiated public when they turn their attention to a science whose many attractions are mared by the repelling array of technical terms with which its professors load it. But all their efforts in this way cannot obscure the sparkling beauty of such a plant as the present subject. Yet it is not so well known in ordinary gardens as it might be expected, from its great beauty and easy culture, to be. It is, in common with many of our most beautiful bulbous plants, a native of the Cape of Good Hope, and a member of the well-known and beautiful group of amaryllids. The snowdrop and snowflake, the daffodil and other narcissus, are comparatively humble, yet very beautiful members of the same family, which will serve to illustrate the character of these vallotas and other amaryllids, but fail to give any idea of their sparkling beauty and the noble form and size of their flowers.

Vallota may be grown in any size of pot, from four and a half inches upwards. In pots so small as those named, only one bulb can be grown successfully, and such pots are only resorted to by growers for market in large towns, and in large private gardens for special purposes of decoration. In larger pots a greater number of roots may be grown, the matter of five in a six-inch pot, and so on, increasing in number as the size is increased The roots should be potted when growth commences, but they do not require potting every year, although they will be the better for being top-dressed every year. If, however, the drainage is kept in good order, they should not be disturbed by being shaken out every year. The offsets from the bulbs increase very rapidly, and tend to rob the flowering bulbs of their strength by overcrowding the pot, and depreciating the quality of the soil at the same time. They are very generally left in this state, struggling for existence too long; and too often excellent stock is lost entirely, or it becomes so debilitated that it requires years to bring them back to vigour. When they are potted they should be placed in a warm greenhouse or cool stove to make their growth, keeping them close to the light, and taking care not to over-water them till they have taken possession of the soil. After they have completed their growth, they should be placed in a cool house throughout the summer, still giving them the fullest exposure to the light, and supplying them with liquid manure twice a week. It is the custom of many to dry them off, which, however, is an error. We question very much whether any bulbous plant should be dried off at any time, but have no doubt whatever as to the unwisdom of drying off vallotas. They should be watered as carefully during their rest period as at any other time. The soil they succeed best in is a good loam of a strong character, approaching to clay; some bone meal added to this is the only addition in the shape of manure which they require; the quantity should not exceed the full of a seven-inch pot to about a bushel of loam. As the supply of water should be very ample, the drainage must be ample also.

ORANGE CULTURE IN SYRIA.

AN official report states that the two districts in which oranges are the most plentiful are those of Jaffa and Sidon. The trade began to assume considerable proportions some forty years ago, when the new Government of Egypt took shape, and is now one of the most profitable industries in the two towns above mentioned. At the present moment Jaffa possesses some 340 gardens, averaging from 2,000 to 2,500 trees in each. The crop of fruit from these may be put down at about 16,000,000. A garden costs from 40,000*f*. to 50,000*f*., and brings in 4,000*f*. to 5,000*f*. per annum. For several miles round Jaffa extends a fertile plain on which water is always to be found at a depth of 40ft. or 50ft. With capital and enterprise, much of this might be planted, and the orange trade doubled in a short time. The present system of irrigation is that of small wells, from which the water is drawn by mules, but experiments have proved that very little engineering skill would be required in order to turn the streams of the river Andjah, some four miles from the town, over the plain. The land near Jaffa would then be cheapened in proportion as the value of that freshly watered rose. At present unplanted land close to Jaffa able to support 2,000 trees is worth £80 to £120 an acre; out at two or three hours' distance it will fetch only 4*s*. to 5*s*. a deunum. The export is carried on chiefly by sailing boats for Egypt and Constantinople, and by steamers for Russia, Trieste and Marseilles Exportation in cases is a comparatively recent introduction, which has given considerable impulse to business with Europe. The orange gardens of Sidon are cultivated on the same principle as those of Jaffa. An acre of land at Sidon is generally valued at from £240 to £280, and is capable of bringing in an income of about £24. The exportation begins in September, and is at first almost exclusively directed to Russia till the winter closes the Black Sea ports, when it is continued to Trieste and Egypt, European cargoes are packed in paper and close cases, the rest are sent in open crates. Each case contains some 300 oranges or lemons, and last years export is reckoned at 20,000 cases, all of which fetched very high prices especially lemons in Russia. The average prices are for 1,000 lemons 150 to 170 piastres, while for 1,250 oranges reckoned as a trade 1,000, the cultivator receives 70 to 80 piastres.

ON PLANTING ROSES.

MUCH has been written on the cultivation of the rose, and various, not to say contradictory, have been the opinions expressed as to the requirements of the queen of flowers. With some, the soil is the all-important element of success; while others hold that climate is of higher importance. Again, the time of planting and the time and the mode of pruning are by certain successful growers considered more essential to success than is generally believed. It must be conceded that every one of the conditions that rose growers hold important to the successful culture of their favourite flower, must be observed in the general sense. No plant responds more gratefully to an intelligent application of its cultural necessities. But few plants, commonly cultivated, have had a larger number of nostrums proposed for it, especially in regard to soil without necessity. And while it may be granted that a free interpretation of the requirements of the rose as conceived of by some is admissible, it must also be stated that a great deal too much has been made of the difficulties which attend rose culture in certain exceptional circumstances. If the soil is too heavy it will not do; whereas it is well known that some of the finest roses ever produced in this country have been from plants growing in some of the densest yellow clay thoroughly drained and richly manured. Given good drainage, and we believe clay or strong loam to be the favourite soil of the rose, especially so in the southern and warmer parts of our islands. In the north it may be feared that the strong growth induced by such soil would not ripen well, and in that case could not flower well or freely, so that a lighter or more sandy soil would be the best in cold, late districts, and where the winters are severe. But in regard to soil, the simple points to remember are to have it thoroughly drained and well enriched with good holding manure, such as cow or stable dung. Manure is of more consequence than the mechanical condition of the soil; but the lighter and more sandy this is the more manure will be necessary. Extremes should also be avoided if possible, very sandy and very retentive clays being equally unfavourable; but as roses must be grown everywhere, the best must be made of each case as it occurs. In the clay endeavour to disintegrate its adhesiveness by mixing with it sand, old lime rubbish, charcoal, or any other mechanical corrective in such proportion as may be wanted to effect the purpose in view. Sandy soil would want to be treated in the opposite way; clay or heavy loam should be added to it to give it better holding power.

Planting should be done in the autumn, as early as the growth is ripened sufficiently to prevent shrivelling of the bark. It is very usual to wait till the leaves have all fallen; but it is unnecessary to do so provided they are all ripened, that is, not soft and recently formed. The ground ought to be thoroughly worked by trenching, and the manure put in and well mixed some time previously. Cut away all bruised and broken branches and all bruised roots before planting, so that there may be nothing to do to the plants after they are planted calculated to disturb or loosen them in their new position. Standards, and even dwarf sorts, should be staked as soon as planting is completed, to prevent their being shaken by the wind. Pruning should not be done till spring. Finish up by giving a good mulching of manure, not too much reduced, 3 or 4 inches thick. Standard roses, owing to the fatal effects of last winter's severity on the stock in the hands of nurserymen, will be very expensive, a dozen plants costing little less than a hundred would do in ordinary years. The chances are that very few, indeed, will be planted. Dwarf roses also, from the same cause, will be somewhat dearer than usual.—*N. B. Agriculturist*.

HERBACEOUS CALCEOLARIAS.

A CORRESPONDENT of the *Gardeners' Chronicle* has sent to that journal the appended brief, but very practically-useful cultural directions, which may prove of value also to our readers:—

Of all soft-wooded greenhouse plants none are more showy and useful than herbaceous calceolarias, which have been so much improved of late years that the flowers have not only increased in size, but are very remarkable for their rich colouring which, among the best strains, is as varied as it is beautiful, and although a large collection may be grown it is very rare that two plants among the whole will be found to yield flowers alike. This great diversity adds much to their value, and renders them doubly interesting, as one never tires of looking them over and examining their peculiar markings, which take so many forms and shapes and are so fantastic in character as to attract the eye of the most casual observer. Were it not for the difficulty many experience in raising the plants, no doubt herbaceous calceolarias would be much more grown than they are, and it is with a view of assisting those that have failed with them that I am about to pen a few remarks on the best way of making a start, as it is the seed-sowing and the attention for a short time after that required the principal skill. One of the chief things towards securing success is the preparation of the soil, and the fillings of the pan or pot in which the seed is to be sown, which should first of all be well drained with crocks and over these some moss placed to keep them free and open, when the final filling may be carried out and the surface of the soil made perfectly smooth and firm. The next thing is to water the soil through a fine-rose pot, when after having stood to drain for a few hours, all will be ready for sowing the seed. This should be done by opening the packet at one end, and gently shaking it so as to make the distribution regular and equal, that the young plants, when they come up, may all have room to grow without any crowding. To get the seed to germinate is the next consideration, and the best situation to induce it to do this is a damp, shady part of a cool-house or border close under a north (south in this country) wall, where the pan or pot should be placed under the protection of a hand-light and kept close, and covered with a sheet of paper for a few days, as the great point is to prevent the drying of the soil, for the seed being exceedingly fine, it does not do to water, for unless great care be taken the seed becomes washed away and lost. To save the necessity for watering at all till the seed germinates, many cover the pot or pan in which it is sown with damp moss, which is a good plan, the only danger being that of leaving it on too long, and thereby causing the plants to be drawn. When moss is not used, and it becomes needful to water, the safest way to apply it is to sprinkle by means of a syringe, so as to pass it on as fine as dew; and if this is done daily when the young plants are up their progess will be most rapid. In the raising of herbaceous calceolarias it should be borne in mind that slugs are exceedingly fond of them, and seem to scent them from afar which being the case it is always advisable to take the precautionary measures to keep them at bay, for should they get at them in the small stage they would eat them all up in a night. To prevent this a good way is to stand the pot containing the young plants on a brick in a shallow pan of water, which will not only keep off the slugs, but maintain a genial moist atmosphere around them, a condition of the air highly conductive to the health of the plants. As soon as these are large enough to handle it will be time to prick them out or pot them off singly which should be done in light rich soil, taking care when doing it not to bruise the leaves which are exceedingly tender. When pricked out or potted they will at once require water to settle the soil about them, and the best place to stand them to give them a start is a nice shaded cold frame, where they can be kept a little close and sprinkled with water every afternoon, just before shutting them up. If all goes well they will be ready for repotting in a few weeks, when they may have their final shift, and may then be gently grown on during the winter, at which season they will require the protection of a

house or pit, where they can have a temperature ranging between 40deg. and 50deg., as in a less degree of heat they seldom do well. Besides slugs, greenfly are very partial to calceolarias, but as their foliage is of an exceedingly delicate nature, great caution is requisite in fumigating, which, to be safe, must be done lightly with tobacco, as paper is more dangerous to use.

TEA.

It is satisfactory to find that the market for Indian tea keeps firm, and, as far as we can judge, there are no signs of the market giving way. The deliveries continue good, and dealers report active inquiries from the country, many firms who have hitherto sold China asking to be supplied with Indian in order to *suit the requirements of their customers*. The small quantity of tea afloat stimulates buyers, and the tendency, as we write, is towards a further advance. We hear that large quantities of fine and finest teas are being kept back in some quarters, in the belief that better prices are sure to be obtainable in a week or two.

No cultivated plant seems to grow so well and readily in Ceylon as tea, and there cannot be the slightest doubt that when Ceylon tea planters have attained the requisite skill in the manufacture of it, they will be able to compete successfully with Indian teas. We have great advantages over Indian tea districts in climate, labour, and means of transport, and we shall be able to put our tea on board ship at a lower cost than it is possible for them to do it. What we require is to give increased attention to "manufacture," and be able to turn out really good teas, and then without doubt tea cultivation will be one of the best investments in the island.

Tea stocks in London are lighter now than they have been for some time, regard being had to the increased consumption. The following are the stocks on 31st October for the past four years :—

	Stocks lbs.	Average monthly consumption, lbs.	Month's supply on hand.
1878	10,462,500	30 90,000	3·58
1879	13,300,000	2,950,000	4·51
1880	17 000,000	3,370,000	5·04
1881	13,200,000	4 100,000	3·22

It will be seen that the increase in consumption has been steady for the past two years, and there seems every prospect of its being permanent. This, with the supplies now going to Australia, should help materially to keep prices up.

The *Pall Mall Gazette* notes that Indian joint stock tea companies have lately been raising their heads : "Their shares are in some cases far above par, and in others at a heavy discount. The recent history of the tea trade *certainly accounts*, pretty well for the rise in the shares, for it is plain that Indian tea has of late gone into consumption at a rapidly increasing pace. Ten years ago our consumption of Indian tea was but an eighth part of that of the Chinese product ; this year it is equal to half the consumption of Chinese tea. The cause of this tendency, as alleged by correspondents of the *Statist*, is the throwing of rubbishy Chinese tea upon our markets. A few years ago there was a great rise in the tea market ; exporters in China swept up all the siftings, second dryings, and inferior stuff which they could lay hands upon in order to take advantage of the rise, and at the same time the growths of the Indian plantations were extended. Somewhat curiously, the latter did not favour us with rubbish, for of all the officially 'condemned' samples last year none was of Indian tea. Apparently there is no gainsaying these evidences of the increased hold which the Indian article is obtaining in the market."

It is a cheering fact that, notwithstanding the steadily increasing exports of Indian tea to Europe, the prices keep high and much firmer than they were last year. Up till last year supplies were in excess of demand, and prices naturally kept low. This year commenced with a materially increased consumption, which has averaged a little over four million pounds per month, while the imports did not increase in the same ratio, having been under four million pounds per month. The result has been a decrease in stocks to the extent of between two and three million pounds during the past ten months. On the other hand China imports have decreased as follows, the calculation being in lbs. for twelve months ending 30th September :—

1878	143,000,000
1879	123,000,000
1880	123,000,000
1881	111,000,000

In spite of this falling off, prices have fallen very materially. In 1878 common Congou—of which the bulk of China teas consist—was quoted at an average price of 9*d*. per lb ; now, the same quality is worth only 6½*d*. It follows therefore that, while in the face of an increasing supply of Indian tea, prices have risen about two pence per pound, in spite of a decreasing supply of China tea, prices have fallen two and-a-half pence per pound. The only conclusion to be drawn from this state of affairs is, that Indian tea is becoming popular, and its virtues are better known now than formerly.

It is instructive to note the effect which the introduction of Indian tea has had in the consumption of green tea in England. In 1836 the total quantity of green tea used in the United Kingdom was 8,857,000lbs., out of a total of 42,807,000lbs. By the year 1848 the figures had grown to 10,053,000lbs., out of 52,231,000lbs. ; and in 1865—the largest quantity consumed in any one year—no less that 19,550,000lbs. of tea of that description were used, out of a total import of 112,450,000lbs. From the year 1865, however, green tea has lost its place in public estimation. By 1875 it had fallen to ten million pounds, out of a total of 164,000,000lbs. ; and in 1880, out of a total importation of 204,198,000lbs. of tea, only 6,165,000lbs. were of the green variety, a result on which the public is to be congratulated, for we are convinced that the use of green tea is injurious to the consumer.

It is, as will be seen, since the introduction of Indian tea, that the use of green tea has been gradually discontinued, and, in lieu of holding the position it held in 1836, at which time nearly a quarter of the total quantity consumed—a pound in every four pounds drunk—was green tea, it now counts only as one pound in 34lbs.

It is well known that green tea is the result of the preparation of the leaf with mineral powders and other substances that are detrimental to health, so it is encouraging to think that by using Indian teas the health of the community is likely to be benefitted. We are inclined to think that on the Continent, where very little tea is drunk comparatively, owing probably to the dissatisfaction that is felt with the ordinary China variety, good teas of Indian growth would find appreciation, and lead to a steady demand for them if they were properly introduced under the auspices of a syndicate.

Indian tea and the companies engaged in the cultivation of the leaf are now attracting the attention of financial journalists in England, and we may look to see the professional speculator shortly entering the field. Referring to the rise in the Indian tea companies' shares which are quoted in this market, a financial writer in the *Pall Mall Gazette* says the recent history of the tea trade certainly accounts for it all, for it is plain that Indian tea has lately gone into consumption at a rapidly increasing pace. Ten years ago our consumption of Indian tea was but an eighth part of that of the Chinese product ; this year it is equal to half the consumption of Chinese tea. The cause of this tendency is the throwing of rubbish y Chinese tea upon our markets. A few years ago there was a great rise in the tea market ; exporters in China swept up all the siftings, second dryings, and inferior stuff which they could lay hands upon in order to take advantage of the rise, and at the same time the growths of the Indian plantations were extended. Somewhat curiously, the latter did not favour us with rubbish, for of all the officially "condemned" samples last year none was of Indian tea. Apparently there is no gainsaying these evidences of the increased hold which the Indian article is obtaining in the market. The *Pall Mall* writer says that the great question, at least for the growers, is whether this stronger position can be maintained. It is calculated that at present prices, at least one joint-stock company in India can get nearly 50 per cent. profit on the average cost per lb., so that we may look for an increase in the growth of Assam teas. On the other hand, the Chinese producer is permanently handicapped by authorised taxes, and by unauthorised exactions of internal small potentates. The rest remains with the season, with the competition among Indian growers, and perhaps also, to a large extent, with the prospects of better railway accommodation between Assam and the shipping ports.

As we have sometimes predicted, the attempt to cultivate tea in the United States of America has proved a failure. The following is from an American trade journal :—

"The yearning after fresh agricultural and commercial conquests is a characteristic of the enterprising Americans. Some of them want to grow tea, and if the experiment should prove that every pound of tea grown costs twice as much as each pound imported, the Commissioner of Agriculture seems determined to grow it. The project, in the opinion of most practical men, is a failure already, but according to the *American Grocer*, land has been leased for twenty years, to be used as an experimental tea farm. It is situated at Summerville, S.C., twenty two miles north-west of Charleston on the line of railway running from Charleston to Augusta. Lands were first examined in Florida in the vicinity of Jacksonville and along the St. John's River as far as Palatka. The Commissioner is firm in the belief that tea culture can be made a profitable industry in the United States. There would be a better chance for success were the enterprise not dependent upon the whims of Congress, the paper referred to says."

The *American Grocer* is in error in saying that it is the connection with Congress that has ruined the scheme ; it may have precipitated the failure, but where the elements of success were wanting, failure was only a question of time. The principal, perhaps the only, element necessary to secure success, which was wanting, was climate, and when the necessary climate was wanting, nothing else could make up for the deficiency. We never doubted that the plant would grow ; it will grow in any moderately temperate climate, but without a certain amount of moisture and heat, coupled with plentiful rainfall, it will not give a yield sufficient to make the cultiva-

tion of the plant a success from a commercial and financial point of view, and we are greatly mistaken in our trans-Atlantic friends if they will continue to cultivate the plant unless it pays.

CHINA TEA TO AUSTRALIA.

A LARGE meeting of tea importers, merchants, and dealers was held October 22nd at the Melbourne Exchange. The Hon. J. Lorimer, M.L.C., presided, and about 150 gentlemen were present.

The Chairman said that the meeting had been called in consequence of the misrepresentations which had recently been made with regard to China teas. It was thought the time had come when it was necessary to give some public contradiction to those misrepresentations, and more particularly to expose the tactics that had been resorted to in making those misrepresentations. He was sure that those interested in the China tea trade would have no objection to those who were interested in promoting the introduction of Indian teas into this market, if they had confined themselves to expatiating upon the alleged superior qualities of those teas; but all must agree that it was certainly not fair and a very un-English thing to seek to damage and detract from the quality of other teas. The meeting had been called to counteract the bad effects which those alleged misrepresentations were calculated to produce. He believed that information would be laid before the public at that meeting which would enlighten them on the subject, and remove a great deal of the ignorance and prejudice which was said to exist. A gentleman with considerable personal experience of the China tea trade was expected to be present, but he had been compelled to leave town to fulfil another engagement. He had, however, sent the following letter:—

"Melbourne, 22nd October, 1881.

"To the Chairman of the Meeting of Tea Merchants.

"Sir,—I regret that my departure from the colony will prevent my attending the meeting advertised for to-day, but I desire none the less to add my evidence to that which will be given at the meeting in contradiction to the supposed shipment of adulterated or spurious teas from Foo-chow.

"After an experience of 16 years in China, I can safely say that so far as I know, there is no spurious or adulterated tea shipped from Foo-chow to the colonies. That a portion of the tea shipped have been once infused, and then refired is, to my mind, as ridiculous a charge as that above contradicted. All who know the manner in which the teas are gathered and packed in the country brought to Foo-chow, and subjected to the inspection of every tea-taster in the place, will confirm what I say. The succeeding crops, or pickings from the same shrub during the same season, differ in strength and flavour. That first crops of successive years also differ among themselves in these particulars, no one conversant with the subject will attempt to deny, but that the severe competition existing in Foo-chow should permit infused leaf to be shipped is to say that in Foo-chow itself tea is not understood. That it is easy to gather the refuse of ten thousand teapots, refire, manipulate it, then run the risk of a sale to the ignorant tea-taster, is in effect the charge made against the Chinese tea merchant, and to do this he must first educate the country people to drink congou, for at present they consume principally other kinds.—I remain, &c.,

"JOHN M. FORBES, Junior.

"Of Messrs, Russell and Co., China."

The promoters of the meeting wanted as much light thrown upon the subject as possible, because one of the worst features of the alleged misrepresentation was the fact that it arose from people whose names did not appear to be known. It was hoped that those detractors of China tea would emerge from their hiding places at that meeting, so that the public might know exactly who they were.

Mr. T. J. Nankivell proposed the following resolution:—

"That this meeting views with indignation the unscrupulous tactics of some unknown persons, designating themselves 'The Calcutta Tea Association,' in attempting to prejudice the public against the use of China tea."

He objected to any person interested in the sale of Indian teas trying to increase their sales by running down the importations from China. If the Indian teas were superior in flavour, or more wholesome—which he for one denied—they would find their way into this market without sensational paragraphs or means of that sort.

Mr. J Everard seconded the resolution. It might be asked, he said, "Has any adulterated tea come into this place?" Some 16 or 17 years ago a large quantity of tea was shipped to Melbourne, the bulk of which was very poor stuff. The bulk of it was, however, sent to New Zealand, and balance of it to England. In the latter place there was a great demand for tea, the licensed victuallers selling it in packets as against the grocers, and large quantities of this poor stuff was bought up for the purpose. (Laughter.) During recent years, however, the tea which had been imported into this colony had been remarkably free from adulteration. Such a thing as adulteration in Foo-chow tea was unknown. With the exception of gunpowder tea he could distinctly say that not a quarter per cent. of the whole of the imports this season had been adulterated or unfit for use. In Foo-chow they had four pickings of the leaf. The first was generally exceedingly good, in fact the finest tea. The second picking was nearly as good, and the third nearly equal to the other two; but the fourth was only picked when there was a great demand for teas of a low quality. The scientific gentlemen who had professed to make an analysis of teas made a great mistake when they spake about exhausted tea. They forgot that the leaves which formed the third or fourth pickings had been left upon the trees during the whole of the summer, and the rain and other climatic effects necessarily deprived them of some of their strength. Then, there was the question of coming up to the standard, but who could say what the standard of teas should be? He (Mr. Everard) had this season tried all the teas which had been imported, even the lowest classes of teas, and not one had been adulterated. Some had had a larger proportion of stalk, which made the tea weaker, but there had not been the slightest trace of adulteration. Some of the teas which had arrived this season had been sold at such remarkably low prices that some people ran away with the impression that they must be adulterated. This, however, was a great mistake. Mr. Everard concluded his remarks by producing several samples of teas in bottles, declaring that the clearer appearance of the China teas was due to their more perfect preparation.

Mr. Bowman, M.L.A., protested against Mr. Everard setting up his opinion against the scientists of the world—against Messrs. Cosmo Newbery and Dunn. (Groans.) Indian tea had been spoken against, but it was a remarkable fact that their sale was increasing in the English market, whereas China teas were decreasing to a proportionate extent. The meeting, he thought, instead of denouncing any particular tea, should have shown a desire to help the Government in bringing in a bill to prevent the importation of adulterated tea. At a sale at Messrs. Fraser and Co.'s the other day he was challenged with having said in Parliament that two-thirds of the tea which came from China was adulterated. He had since procured a proof of his speech from the *Hansard* reporters, and he found, as he stated at the sale, that he qualified his remarks with the words "the lower classes of China teas." He was prepared to challenge any tea merchant for £500 to disprove one word which appeared in the *Tea News* about the China teas. If they accepted the challenge, and disproved what had appeared in the *Tea News*, he would send the £500 to the Hospital Fund.

The resolution was then carried unanimously.

Mr. J. Jackson proposed the next resolution, which was—

"That in the opinion of this meeting, the ordinary importations of tea from Foo-chow are genuine and unadulterated, and the comparisons by analysis of India and China tea which have lately been published are calculated to create in the public mind erroneous impressions regarding the purity and wholesomeness of Foo-chow teas."

From his experience in the tea trade, he believed it would take a great deal to upset the established interest in China teas in this colony. The merchants of Melbourne had shown great enterprise in securing genuine teas, and the comparison of the analyses which had been made was no fair test of the quality of various descriptions of teas.

Mr. A. Harvey seconded the motion, and said that adulteration had never been practised with Shanghai or Hankow teas, and seldom in Foo-chow. Anyone conversant with our imports knew that at the present time the total import of adulterated teas (that was low gunpowder and low Tayshan congous) was infinitesimal as compared with the balance. No analyst could tell so well as the professional taster whether a tea was soundly cured, sweet or flavoury. A coarse, rank earthy tea would give a splendid analysis extract, but it would be very unpleasant to drink. Analysis was therefore no guide in determining which tea was pleasant to consume and which not.

Mr. Bowman explained that Messrs. Cosmo Newbery and Dunn have made their analyses from 27 samples of tea purchased at random at various establishments in Melbourne, and he agreed with them that the China teas were adulterated.

Mr. A. Harper thoroughly approved of the resolution, but as they as merchants were interested in the sale of both China and Indian teas, he thought it would have been better for the meeting to have confined itself to explaining away the misrepresentations which had been made, and to assisting the Government in passing a bill to prevent the importation of adulterated tea.

The resolution was carried.

Mr. J. Webster then moved—

"That the public statements made by persons engaged in the Indian tea trade, to the effect that a pure China tea is now difficult to obtain, is a gross and scandalous misrepresentation of facts."

This was seconded by Mr. J. Whiting, and agreed to, Mr. Bowman being the only dissentient.

Mr. M. England next proposed—

"That it is desirable that a bill to regulate the importation of tea be passed as soon as possible, and that Messrs. Nankivell, Harper, Everard, Whiting, and Jackson be appointed a committee to watch the bill now before Parliament, and to assist its promoters in making it workable and efficient."

Mr. Bowman seconded this resolution, which was carried *nem con.*

A vote of thanks to the chairman concluded the proceedings.—*Argus.*

MATHEINE.

WHAT is Matheine? It will not be sufficient reply to this question to merely state that it is a new drink, which, in the future, must take equal, and in some respects, even higher rank than tea, coffee, chocolate, and the other well-known domestic beverages that stimulate but not inebriate" the imbiber. It is, in fact, so important an addition to our social resources that we feel it to be a duty to make a more particular record of its characteristic merits. To some of our readers Matheine will present itself as an old friend in another guise; for it is the product of a process discovered by Mr. A. K. Mackinnon (who in connection with the Kopf Company has introduced so many new and excellent food preparations) from the dried leaves of the Ilex Paraguyensis with which South American communities are so familiar under the name of "yerba maté." In the *Revue Scientifique* and other journals of Europe, public attention has been directed to the special advantages of this South American drink. It has been represented and truly represented, as possessing all the cheering and refreshing properties of tea and coffee, without producing any of the unpleasant effect upon the nerves too frequently attendant of an over liberal use of these popular beverages. But the mode in which it is used is so opposed to established custom in our own and other countries of Europe that journalistic advocacy must have failed to bring it into general consumption on this side of the Atlantic. The common practice in Brazil and the River Plate, where it is extensively used, is to pour boiling water on some of the powder (consisting of dried leaves and twigs of the yerba maté shrub), and then to suck the infusion through a tube, which is passed from mouth to mouth, as the "calumet of peace" under certain circumstances is said to have passed round a circle of North American Indians. This difficulty has, however, been altogether removed by Mr. Mackinon. Matheine, which is in a liquid form, can be utilized with the greatest facility while it may be fairly described as a boon to the weakly and infirm, and of the utmost service to hardworking people in every grade of society. Professor Wanklyn gives the following analysis of this substance; Moisture, 6.72;

ash 5·86; soluble organic matter 25·10, insoluable organic matter 62·32. Another analytical chemist Signor Parodi, now resident in Buenos Ayres, gives a qualitative analysis, viz., Cafetannate of Theine, Cafetannic acid (free). Chlorophyl and Wax, Resin, Gum and Vegetable Albumen, Lignine, and the ashes contain salts of Potash and Lime, Oxide of Iron and Manganese and of Silica. Another analysis demonstrates the presence of Theobromine, which is the active principle in cocoa. However, we are bound to say that, up to the present no satisfactory analysis has been made. We take the following as to its properties, from an announcement of the Kopf Company:—

We know that the infusion of this interesting shrub possesses the properties of tea, coffee, and cocoa. It is sedative and stimulant; prevents the waste of tissues; increases the activity of the brain, and hence is invaluable to brain workers; causes the secretion of milk, and, therefore, of great value to nursing mothers; this which shows its nutritive power is amply exemplified in the fact that the gauchos (native horsemen) undertake long journeys on horseback, at times as much as 60 and 80 miles in a day, with no other aliment but three or four maté cups of their favourite infusion.

To military men this substance would be invaluable, as it would enable them to undertake fatiguing marches better than any other beverage known. Sportsman, angler, and traveller would alike benefit by its use in lieu of strong alcoholic beverages.

To South Americans, not less than Europeans, Matheine should prove exceedingly acceptable. The yerba maté infusion, as actually taken by the former, namely by suction through a tube with a perforated bulb, is liable to serious objection, as the finer particles are swallowed, and in process of time accumulating form irritating concretions in the stomach to the serious injury of the health of the individual. In its liquid form this is altogether avoided. We should add that the proportion is one to two teaspoonfulls to an average sized tea cup of boiling water, with milk and sugar to taste.—*Brazil and River Plate Mail.*

COFFEE.

From a pamphlet on Liberian Coffee in Sumatra, we gather that this variety yields 92 per cent. of caffein, as compared with 56 per cent. obtained in ordinary Java coffee.

From a return recently submitted to Government, we gather that in Cochin about 7,794 acres have been taken up for coffee, of which only 1,436 have been planted in Travancore; the extent of land planted with mature and immature plants is 16,775 acres against 37,067 taken up. For the entire presidency, the figures are as follows: mature plants, 78,822 acres; immature plants, 13,463 acres; not planted out, 83,925 acres; total taken up for coffee, 176,210 acres; approximate yield of coffee, 21,492,682 lbs. The Travancore estates give an average of 175 lbs. of coffee per acre of mature plants against 323 lbs. in Cochin, and 197 lbs. in the Wynaad.

Coffee-leaf disease has unfortunately not only continued to spread in the plantations at the westward end of the island of Java, but has also appeared in several gardens in Central Java. The report of a Commission appointed by Government to investigate the origin of the disease tends to show that it is mostly met with on poor or worked-out grounds, and that the succession of wet seasons has greatly contributed to the spread of the contagion; it is, however, hopped that a recurrence of dry years will cause a marked decrease in the percentage of trees attacked. The presence of the disease may be detected in two ways, either by the appearance of light green spots on the upper side of the leaf, or by the presence on the under side of a collection of an orange-coloured kind of dust. In plants severely attacked, the leaves turn black or brown, and rapidly fall off.

"The Commission, appointed by the Netherlands Government to investigate the coffee leaf disease in Java, has reported the result of its enquiries. These are said to establish the following conclusions as to the causes of the disease—Poverty of soil either naturally or by being worked out; abnormal degree of continuous wet weather. In Java the disease is detected in two ways—the appearance of light green spots on the upper side of the leaf, or the presence underneath of an orange colored kind of dust. Severe attacks are known by the leaf turning black or brown, and rapidly falling off.

"The Commission recommend as a mode of suppression the following simple measures:—

"1. The hoeing up of the ground surrounding the trees beyond the spread of the branches to the depth of about 6 inches, leaving the clods turned up intact.

"2. The construction of ditches or holes about 18 inches deep between every intermediate row of plants, distributing the earth dug out proportionately over the garden.

"3. In irregular gardens, or wherever the construction of ditches is impossible, the formation of holes about 18 inches in diameter at an interval of every four trees, dispersing the turned-up earth among the plants.

"4. The careful manuring of the ground at the distance of about a foot from the stem of each tree, and covering the manure with earth.

"If these measures are really effective, the general immunity from disease of coffee plantations in this district, may be attributed to them, as the holes, or as they are called here renovation pits, are very generally adopted both as receptacles for manure and for the wash." That is to say, the mode suggested is to cultivate more liberally the very cure we have been suggesting all along, as the only one worthy of a moment's consideration.

NEW SUBSTITUTES FOR COFFEE.

(Translated from the "Indische Mercuur.")

In a German paper it is remarked that the leaves of the coffee tree are really better adapted for use than the coffee leaves themselves. They are specially rich in caffein and tannin. According to a chemical analysis of Professer Henhouse, the leaves of the Sumatra coffee contain 1·26 p. c. of caffein, besides tannin, but very little sugar and fat. The amount of soluble constituents is much greater in the coffee leaves than in the beans. As caffein and tannin are, by far the most important constituents of coffee, the use of coffee leaves as a substitute has much to recommend it. The leaves should be simply dried—as is the case with tea leaves, and could be brought into the market in this condition. The preparation of the dried leaves could be done in such a way that they could be roasted in the same manner as coffee, with the addition of about 10 p. c. of sugar, and coffee made from the ground powder by means of boiling water. A coffee sustitute, consisting of a mixture of roasted coffee leaves and roasted corn, can in a certain sense entirely take the place of coffee, as this mixture in consequence of its containing caffein and aromatic products of roasting, which owe their origin to the tannin, approaches very closely to the composition of true coffee, whilst in the ordinary substitutes for coffee no trace is to be found of these substances. The history of coffee substitutes is more than ordinarily interesting: the first attempt at the manufacture dates from the second half of last century. In the year 1790 there were already in Magdeburg coffee substitute manufactories, which prepared the chicory root. This industry extended to such an extent, that in 1840 there were already 41 coffee substitute manufactories with 2,500 workmen. What success has attended the manufacture of coffee substitutes in other countries may be judged from the fact that in France alone six million kilograms of chicory root are consumed, not to mention all the other materials from which coffee substitutes are manufactured to an equal extent. The continental theory of Napoleon I. gave a specially strong impetus to the manufacture of artificial coffee, as it did also to the manufacture of beetroot, sugar and soda. From the narrative of travellers we know that coffee substitutes are used by other nations also. In Arabia a kind of coffee is prepared from the roasted seeds of the so-called Durrah plant, and sold under the name of Sudan coffee. Several negro races prepare other seeds in like manner, and the Tunguses use even the seeds of a poisonous plant, viz., the henbane. In our August number (I. M. 1880) we spoke of several new European coffee substitutes, and we shall not therefore refer to these, except to say that they have none of the effects on the nervous system which true coffee produces. It therefore seemed not uninteresting to notice the use of roasted coffee leaves, as in these are found the substances (especially caffein) which exactly constitute the peculiarities and characteristics of coffee.

CINCHONA.

"The Government reserves the right to make Public Roads through the land to be granted without paying any compensation except for the value of Cinchona or other valuable trees actually destroyed in the course of the work.'

This is one of the rules for the sale of waste land for Cinchona cultivation in Madras, and is so far liberal. It is just possible, however, that the amenity of an estate may be utterly destroyed by a public road.

Dr. Shortt writes to the Madras Horticultural Society from Yercaud:—"Cinchona hitherto on these hills has been simply as an experiment: one or more trees only were to be seen on a few estates. Of the different varieties, the *Cinchona Succirubra* thrive well here, and this variety is best suited to these hills. Efforts are now being made by a few planters to extend cinchona cultivation, and on my estate self-sown seeds of this variety were found growing in the vicinity of the parent plants, and the trees are so extremely prolific in their seed productions that I have been able to collect and distribute the seeds freely. The difficulty of getting the seeds to germinate is rather trying, as the process requires much care and attention, more especially without the aid of a propagating house. Of the cinchona trees on my estate one seems a hybrid, and on sending specimens of the flowers and leaves to Mr. Jamieson, the Superindent of the Government Gardens, Ootacamund, that gentleman recognized it as one which, he says, has been named Cinchona Lanosa. This plant also seeds very freely and largely."

SERICULTURE.

SILK-GROWING IN BURMA.

Rearing silkworms, though a very profitable occupation, is not looked upon with any favour in Burma. To get the silk the pupæ must be killed; and the taking of life of any sort is an impiety always looked upon with great horror by all rigid Buddhists. Silk-growers are classed together with professional hunters and fishermen. The four states of punishment yawn for them, and their portion will be in the lowest abyss of "Gna-yeh," the lowest hell. Still there are colonies of silk-growers in various parts of the country; but they live apart from the rest of the inhabitants, as a rule, and often have entire villages to themselves. Colonel Horace Browne, who paid some attention to the industry in his district, states that the cultivators near Prome, where more silk is produced than in any other part of Burma, are nearly all Yabehns—a race of the same stock as the Burmese, but despised by them independently of their crime in the way of taking animal life. They usually live on the hill-sides, occupying themselves, like the poorer Burmans and Kareens, with toung-ya cultivation: that is to say, clearing the forest-lands on the mountain-slopes, burning the felled timber just before the rains, and then sowing the ground [thus enriched by the wood ashes] with rice, cotton, or oil-seed. The system is laborious and not viewed with much favour by the authorities; for the toung-ya soil, hardly exhausted by the single crop grown off it, immediately produces a dense forest growth of no use to anybody. Silk production is a much simpler matter, involving the least possible amount of toil and at the same time being very much more profitable. Moreover, the Burmese mulberry-bush, which is quite distinct from the

ordinary *Morus Indica*, does not grow well on alluvial soil. It flourishes, however, on the hill-sides, where the Yabehns mostly live. The silk obtained from caterpillars nourished on the leaves of the hill shrubs is very much better than that obtained from lowland mulberry-bushes. Thus it happens that the richer Burmans down in the alluvial plains have not the same temptation to impiety which confronts the Yabehns up in the hills; and the number of silk-growers is, for a similar reason, limited.

It is certain that neither the silkworm nor the mulberry-bush are indigenous in Burma; and, as Colonel Horace Browne points out, it is more probable that both were introduced from Western China, down the valley of the Irrawady, than that they came over the hills, through turbulent mountaineers, from India. The shrub does not grow much more than ten feet high, and seldom produces good succulent leaves for a longer period than three years. After that the plants are apt to get coarse and stringy, and the cultivators ordinarily abandon the plantation or root out the bushes and plant new ones. The shrub will not flower, and has therefore to be propagated by cuttings. The Burmans call it the poh-tsabin, "the tree the silkworms eat." There is another tree—that from the bark of which the Burmese get the coarse paper used for their parabeik, or note-books, the leaves of which the caterpillars will eat; but the silk thus obtained in much coarser, and recourse is therefore had to the ma-hleing-bin only when the mulberry-trees give out. In any case, however, the silk produced in Burma is of a very inferior kind. It is rough and coarse; but it is all the better suited for the strong loongyees and putsoes in use for ordinary every-day wear among the Burmese, the finer cloths all coming from China or Manchester.

The whole process of growing the silk is of the simplest possible character, and is exactly suited to the Burmese were it not for the necessity of killing the pupæ. Silk can, indeed, be spun from the cocoons out of which the moths have escaped; but it is very much coarser even than the ordinary silk and commands somewhat less than half the price. Except the occasional trouble of strolling out for a few leaves, there is almost nothing to be done; and the whole operations are carried on in the rickety bamboo hut of the cultivator, within a yard or two of the place where his food is cooked. The caterpillars do not seem to care a whit for the smoke or the dirt; and the pupæ are equally callous to the fumes of tobacco which circle about them constantly during the few days that remain to them before they are stewed. The female moths are placed upon pieces of coarse cloth with palm-leaf lids put over them. The eggs stick to the cloth and form a compact little circle. A day or two over a week suffices to produce the larvæ, and these are then thrown upon flat trays, made of strips of bamboo plaited closely together and guarded by a slightly raised edge. For four or five days the little caterpillars are fed on finely chopped mulberry-leaves, the tenderest that can be found. After that they change their skins, and, beyond getting plenty of leaves, do not receive much attention. They are sturdy creatures, and they would need to be, for they are often very roughly treated. The trays are scarcely ever cleaned, and if the larvæ are to be shifted from one tray to another, they are scraped up in handfuls and thrown down as if they were bits of wood. Gauze or mosquito-netting is usually thrown over the trays to keep away the ichneumon flies which otherwise deposit their eggs in the silkworm's skin, which of course kills him. In about a month's time the caterpillar is full grown. He is then bundled into a fresh tray; in which there lies wound about in the form of a spiral, a narrow plaited bamboo strip. The ripe larvæ are thrown into this with as little ceremony as if they were pebbles. In about a day's time they have spun their cocoons, fastening them to the slips of bamboo. These are torn off and kept in baskets for a day or two, when a pot, with water in it, is filled with the pupæ which are set to simmer over a slow wood fire. From a triangle over the pot is suspended a small bamboo reel, and down below near the pot is a wooden cylinder. The reeler is usually a girl. She fishes about after a time in the simmering pot, and, catching a few threads of silk, passes them over the reel and down to the cylinder, to which they are fastened. She then turns the handle of the cylinder, winding on the silk, and at the same time constantly fishing up and fastening on new filaments, which she does by means of a light bamboo double-pronged fork. Not the least trouble is taken to keep the silk clean. Any rubbish that may be floating on the surface of the water is wound on to the cylinder without an attempt being made to disengage it. When all the silk has been got off the cocoons and wound on to the cylinder, the pupæ are taken out of the water and fried in oil to furnish a dish for the family dinner. They are not by any means unpleasant—tasting, barring the oil, very much like roasted chestnuts; and indeed the dish is considered a great dainty.

The silk growers mostly sell their silk. A loom is to be found in almost every Burman's house in the country; and in Prome and Shway-Doung, as being close to the place where the silk is produced, great quantities of articles of dress are made for sale. The native-grown silk is only used for every-day clothes of simple patterns; the more elaborate being all worked from imported Chinese silk. The silk is bought raw, the separate filaments twisted into a thread by means of a wheel, and then made up into hanks. These are boiled in soap-and-water and are then ready for the dye. The commonest colours are green, yellow, orange, different shades of red and light blue; black and dark blue are only in favour with the Shans. The dyes are obtained from various jungle seeds, roots, flowers, leaves and barks; the yellow dye obtained from the wood of the Jack (*Artocarpus integrifolia*) being reserved for the monkish robes. After being dyed, the thread is unwound again. The weaving machine is very much like the old hand-loom still occasionally seen in out-of-the-way parts of England. The operators are almost always young women; and they are very clever at working the treadle and shooting through the shuttle, while talking all the time to village gossips or admiring swains. Some of the tamehns (the women's dresses) are extremely intricate in pattern, and require between twenty and thirty shuttles. The treaddle raises and lowers the alternate threads on the warp. Except the rough dresses and the most complicated in pattern, however, not many native-made clothes are worn now. The townspeople prefer the showy and cheaper imported articles, and, though the Manchester goods are too frequently adulterated and do not last long, yet this does not trouble the Burman much for he is fond of a change of dress, and, unless he is poor, will never wear a putsoe, except about his house, after it has been washed. All the more elaborate designs are, however, native-made. The "dogs' tooth" pattern is almost confined to Mandalay court looms. The achit putsoe or tamehn, of a wavy complicated design, which middle-aged Burmans remember as being the cherished object of desire of their young days, is now considered rustic. Young Rangoon will tell you that you always know a Tan-tha (a jungle Wallah) at the Pagoda feast by his wearing an achit putsoe; and although it may cost from 150 to 800 rupees, that does not redeem it in their eyes.

SHWAY YOE.

—*St. James's Gazette*.]

SILK-GROWING IN CEYLON.

WITH reference to Dr. Vanderstraaten's paper on the subject, we may call attention to the following extract from our "Review of Agriculture and Planting Enterprise in Ceylon," published in our Handbook for 1876-78:

"There is a spot on the banks of the Kelani river 3 or 4 miles above the Bridge of Boats *en route* to Hanwela 'Orte Saide' or Silk Garden where the Portuguese are believed to have fed silkworms. The Dutch unsuccessfully attempted to propagate the silkworm and produce silk at Jaffna. In the British period silk has been tried more than once, more particularly by a coffee planter (Mr. H C. Bury), in Haputale, on whose produce a favorable report was received by us a few years ago, from a Coventry firm, but the difficulty of securing careful skilled labour and the injurious effects of thunderstorms on the silkworms prevented the continuance of the experiment. Sir Wm. Gregory took a great interest in silk-growing, as in all other experiments with new products. In 1872 he reported that the mulberry tree grows quickly and vigorously in Ceylon, and the worms are reported to be hardy and to thrive well, but the difficulty was to find patient and skilled hands to wind the silk. Accordingly he recommended the dried cocoon to be sent to Europe to be spun, but the cost of female labour in England is another difficulty. Sir Wm. Gregory introduced and distributed Japanese silkworm eggs in Ceylon."

Dr. Vanderstraaten writes to us in reference to his paper:—"I was indebted to Mr. Alex. Geddes of Moratuwa for the floss silk exhibited. The white is from the Bombyx mori, a Chinese silkworm; the brown is from the Tussur silk moth (Antheroea Mylitta, or A. Paphia). Mr. Geddes finds that the Tussur moth cannot be domesticated. Mulberries are plentiful all over the island, and can be freely cultivated from cuttings; in two to three years each tree will supply 5lb. weight of leaves. As a new industry mulberries can be cultivated with tea. It is a profitable and interesting amusement for women and children. Every year about £1,500,000 is sent from Europe to China and Japan for eggs; principally from Italy where mulberries are plentiful. It is introduced into orphan schools, reformatories, prisons, leper and lunatic asylums: supplies of eggs can be sold to the general public. The early history of Ceylon from Valentyn in 1663 to Tennant has been consulted. In 1663 the Dutch cultivated it in Colombo and Jaffna. When the English came to Ceylon a garden of mulberries and buildings for the rearing of silkworms were found at Orte Saide (Portuguse for silk-garden) near the Bridge of Boats at Kelani. The silkworms exhibited at the Polytechnic Exhibition were from Father Palla's supply. It ought to be tried more largely now that the experiment has been successful as shown yesterday."

We are glad to learn that an experiment is being conducted so far with success in "silk-growing" in lower Dimpula, and we learn from another gentleman, who has taken considerable interest in the matter that though his experiment in Colombo was a failure, he his trying again with more chances of success, and is inclined to experiment with the very abundant "lettuce" (pisina alba) tree leaves instead of those of mulberry. If the silkworms thrive on the leaves of this plant, the industry ought to prosper in and around Colombo.—*Ceylon Observer*.

TOBACCO.

TOBACCO CULTURE IN AUSTRALIA.

MANUFACTURERS of Victorian-grown tobacco all admit that the best leaf grown in the colony is that from the North-Eastern district, the bulk of which is grown on the flats of the King and Ovens rivers, the aspect, soil, and climate of which appear to be more suitable to the growth of this crop than in any other locality in Victoria. At present there are about 500 acres of land on these rivers under tobacco culture, the principal growers being Messrs. Izzard, Smith, and Bowie. The plan which has been found to be the most successful is to let the land to parties of Chinese on shares in the crops, the owner of the land finding provisions for the workmen. Chinese cultivators have been found to possess more patience in growing tobacco, which requires constant attention, than any other class of labourers. The crop is a highly remunerative one when all goes well with it, but there are many difficulties to contend with. One of the worst of these is a grub, which attacks the roots, and which, unless removed speedily, destroys the plant. This necessitates constant and minute inspection of the crop, and for this work Chinese labourers are more suited than Europeans. The tobacco crop suffers from severe frosts, but it is believed that these may be avoided by planting at a later date than has been the rule hitherto. In very wet seasons the plant is liable to suffer greatly from mildew, whereby its value is greatly depreciated. Occasionally a heavy hailstorm has been known to utterly ruin the season's crop. A good crop will, however, make up for two indifferent seasons. About 15cwt. of leaf tobacco to the acre is regarded as a good crop. Before he turned his attention to hop culture, Mr. Henley was a large grower of tobacco, which he manufactured on the farm, 25 tons of manufactured tobacco being turned out yearly. At present he has entirely given up tobacco cultivation. For a long time the general crops in this district were sold to Melbourne manufacturers in the form of leaf tobacco, but the growers complained that they did not receive a fair value for their produce, and to meet this difficulty the town council gave the sum of £1,000 to encourage a Chinese firm to establish a tobacco factory in Wangaratta. This speculation answered very well, about 80 tons of manufactured tobacco being turned out of the factory per annum. Owing to one of the firm returning to China, there was a probability that the business would be discontinued, and a company has lately been formed with a capital of £2,000 to carry it on. The premises and plant of the Chinese firm have been purchased, and considerable alterations and additions will be made. The growers of tobacco in the district are the principal shareholders in the new company. As fully two-thirds of the tobacco grown in Victoria, and certainly the finest quality is grown on the Ovens and King rivers, there is a good prospect of success for the new company. The tobacco growers estimate that from 6*d.* to 9*d.* per lb. for the best quality of leaf will pay them well. Last year the price was 4*d.* per lb. The shareholders of the new company expect to do a large trade, as they will have nothing but the finest leaf tobacco in the country to work up.—*Australasian*.

ANDREWS' INFALLIBLE APPLICATION.

A certain and effectual Cure for Reumatism, Gout (Acute and Chronic), Sciatica, Lumbago, Neuralgia, Tic-Doloureux, and all Painful Affections.

ANDREWS' INFALLIBLE APPLICATION.—This matchless and never-failing remedy has been extensively used by the Proprietor for some years in his private practice, and its universal success in every case has determined him to make it generally known. Various preparations have been introduced to the Public purporting to cure Rheumatism, Gout, and other painful maladies, but *nothing* yet produced has given instantaneous relief and worked such marvellous cures as ANDREWS' INFALLIBLE APPLICATION.

ANDREWS' INFALLIBLE APPLICATION is the result of protracted and costly experiments extending over many years; and out of the numerous cases brought under this treatment, not in one solitary instance has it been known to fail, but in every instance a perfect cure has been effected. Extraordinary cases of many years' standing (which had been pronounced by the Faculty incurable) of persons bedridden and utterly incapable of movement, from Gout and Rheumatism in their most acute form, have succumbed to this wonderful application in a few days, and have been enabled to return to their accustomed habits. In all slight cases a cure is effected immediately.

ANDREWS' INFALLIBLE APPLICATION.

"One Trial will convince the most sceptical."

ANDREWS' INFALLIBLE APPLICATION is the result of long experience in the treatment of the painful complaints which it cures.

ANDREWS' INFALLIBLE APPLICATION is no quack imposture, but a genuine *bonâ fide* therapeutic agent which has worked marvellous cures, and possesses wonderful curative properties.

ANDREWS' INFALLIBLE APPLICATION is allowed by those who have tried its wondrous action to be unequalled by any other remedy.

ANDREWS' INFALLIBLE APPLICATION only requires a trial to prove its extraordinary powers, its prompt and certain action, its effectual and speedy relief from all local and painful affections.

ANDREWS' INFALLIBLE APPLICATION cures Neuralgia, Sciatica, Gout, Rheumatism, Tic-Doloureux, Head-ache, Brow Ague, Nervous Pains, Tooth-ache, &c., &c.

In Bottles, 1s. 1½d., 2s. 9d., and 4s. 6d., of all Wholesale Medicine Warehouses, Druggists and Chemists throughout the Kingdom. Each Bottle protected by Government Stamp.

CAUTION.—Observe the name of the Proprietor **G. J. ANDREWS**, on the Stamp, without which none is genuine.

PREPARED ONLY BY

G. J. ANDREWS, Central Medical Hall, 28A, Little-St., Andrew's St., Upper St., Martin's-lane. Established over 100 years. LONDON.

TO INVESTORS.

AN excellent opportunity occurs for securing a Half Share in a well-established Tea Estate, situated in a most healthy part of the Neilgherries, and only 30 hours by cart and rail from the nearest sea port. Labour and Fuel are both abundant in the neighbourhood.

The Estate which is upwards of one hundred acres in extent, comprise a large well-built house with stables and offices complete, factories, &c., with machinery worked by water power. About seventy-two per cent. of the acreage is under tea, more than half of which is in full bearing. There are besides about twenty thousand Gum and some Cinchona trees on the plantation. Price of Half Share, £2,750 Sterling.

N.B.—The refusal of the other half share could probably be arranged if desired.

For further particulars, apply to Nicholls & Co., 8, Old Court House-street, Calcutta; or 1, Whitefriar's-street, Fleet-street, London, E.C.

JEYES' PERFECT PURIFIER:

SUPERSEDES CARBOLIC;

Being four times as efficient and does not Poison, Stain, or Burn.

SUPPLIED TO

H. M. Queen Victoria, Prince of Wales, Home Office, War Office, H. M. Prisons, Corporation of London, P. & O. S N. Company, Commissioners of Sewers, Board of Trade, &c.

Jeyes' Perfect Purifier.—*From the* "HOME OFFICE."

"The disinfectant of the future. Not dangerous as carbolic. The soap I like very much."

Jeyes' Perfect Purifier.—*From* LONDON HOSPITAL.

"Please send 6 gallons. This diluted will make 600. It is the cheapest, and best of the many disinfectants tried at this Institution."

Jeyes' Perfect Purifier.—JAS. MACCALL, F.R.C.V.S, *Principal Professor, Glasgow Veterinary College.*

"When applied to the skin, mucous membranes, and wounds and parasites, is superior to carbolic acid, and is perfectly soluble in water, is regular in action and without the carbolic smell."

Jeyes' Perfect Purifier.—DR. CAMERON, F.R.C.S., *Medical Officer for Dublin,*

"Most powerful sanitary agent; unsurpassed by any other. Will powerfully ward off attacks of contagious diseases. Should be used in all cases of malaria and infected districts for foreshores, sewage, &c.

Jeyes' Perfect Purifier.—PROFESSOR PEPPER, *Royal Polytechnic Institution.*

"First among disinfectants;" "safe and agreeable." Its employment by agriculturists for destroying insects and for preserving wood-work cannot be too strongly recommended."

Jeyes' Perfect Purifier.—ROYAL CANINE SURGERY.

"For destroying vermins, and improving appearance of dogs beyond improvement."

JEYES' SANITARY COMPOUND CO., LD.,

64, Bishopsgate-street, Within

LONDON.

Prices, 1s. 1½d. 2s. 3d. 4s. 6d. and 11s. per bottle.

TIC-SANO

The Great Vegetable Remedy.

TIC-SANO. "A MOST WONDERFUL

TIC-SANO. AND SURE CURE."

TIC-SANO. —*Morning Advertiser.*

TIC-SANO is a vegetable remedy which does not contain colchicum (a drug which, although relieving pain for the time being, is disastrous in its after-effects), but is a tincture of some of the most powerful purifying roots of the New World. It is not an ordinary quack nostrum, but is the result of many years of intelligent study and experiment, and is placed before the public as a standard medicine which will do all that is claimed for it, without leaving any hurtful results.

TIC-SANO will always give INSTANT RELIEF IN

TIC-SANO, NEURALGIA,

TIC-SANO, RHEUMATISM,

TIC-SANO, GOUT,

TIC-SANO, SCIATICA,

TIC-SANO, LUMBAGO and GRAVEL,

TIC-SANO, NERVOUS and SICK HEADACHES.

TIC-SANO. It is needless to expatiate upon the virtues of this medicine when so many medical men of the highest standing, have, without solicitation, pronounced so decidedly in its favour. They have EFFECTED CURES with this remedy after trying all others in vain. Any information or advice will be given on application to the Head Office, as below.

TIC-SANO

"Kew-green, Surrey, January 1880.

DEAR SIRS,—

"I have much pleasure in speaking favourably of Tic-Sano; it certainly relieves promptly many forms of neuralgia, rheumatism, atonic gout, affections, and pains of the occipito frontalis, chronic painful periostitis of the tibia, ribs, lumbago.

"The value of Tic-Sano is enhanced by its leaving no ill effects; no headache, no stomach derangements ever follow as a consequence of its administration.

"To secure the efficiency of this remedy in persons above 50 years of age, and who have suffered a good deal from neuralgic affections, it is necessary that the doses should be higher than those advised in your circular.

"J. C. ATKINSON, M.D."

TIC-SANO. Order through all Chemists and Druggists, who, if they have it not in stock can easily obtain it from any wholesale house.

Beware of Worthless Imitations.

JOYCE & CO.,

24, OLD JEWRY, LONDON, E.C.

SEVEN PRIZE MEDALS AWARDED.

GOODALL'S HOUSEHOLD SPECIALITIES.

A Single Trial solicited from those who have not yet tried these splendid preparations.

Goodall's Yorkshire Relish

The most delicious sauce in the world; enriches hot joints, stews, chops, fish, &c.; with soup it is charming; blends admirably with all gravies; makes cold meat a luxury; makes the plainest viands palatable; the daintiest dishes more delicious; a great addition to cheese; every dish is improved by its addition; epicures pronounce it the best sauce; beware of colourable imitations.

CAUTION.—On each label is our Trade Mark, Willow Pattern Plate, and name, GOODALL, BACKHOUSE and Co. No other is genuine.

Whatever prejudice may have existed at any time on account of its cheapness has become entirely dissipated by the daily use of this really good sauce. We merely solicit a trial from those who have not used it, after which we feel confident they will use no other sauce.

Over four million (4,000,000) bottles sold annually. Largest sale of any sauce in the world. Sold by Grocers, Oilmen, Chemists, &c., in bottles, 6d., 1s., and 2s. each.

TESTIMONIAL.—"4, Wimbourne Street, New North Road, London, N., 18th May, 1875.—Gentlemen,—I have not the pleasure of knowing you—never met you, never saw you—but still for a great length of time my sideboard has never lacked your celebrated YORKSHIRE RELISH, and it gives me very great pleasure to forward this Testimonial in its favour, provided you think it worthy of your acceptance. My sedentary habits as a writer for the magazines, &c., very often makes me exceedingly peevish with my meals, but still, no matter what I have, your YORKSHIRE RELISH always brings me to. Sometimes I have a hot joint that it enriches, sometimes cold meat that it makes exceedingly tasty and palatable—with soup it is charming. And sometimes, when the press is waiting for matter, I can make a very good makeshift for dinner with a roll steeped in it; so that in each and every sense of the word I cannot speak too highly of that which I find so good, so useful, and so cheap. If it is likely to be productive of good you are quite at liberty to publish this. —Yours truly, the Author of 'Grace Darling,' 'Harriet Stanton,' 'The Wreck of the Royal Charter,' &c.—To Goodall, Backhouse, and Co., Leeds.

Goodall's Quinine Wine

The best tonic for invalids; the cheapest, because the best; invaluable for neuralgia; testimonials to its efficacy innumerable; pre-eminent for purity and strength; recommended by every one who has tried it; thousands benefited by its use; awarded seven prize medals.

Highly recommended by the most eminent physicians, and acknowledged to be the best and cheapest tonic yet introduced. Strengthens the whole system, and stimulates the appetite. It is invaluable for Indigestion, Nervousness, Gout, Rheumatics, &c. Has proved an invaluable and agreeable stomachic to all suffering from general debility and loss of appetite. The best restorative for the weak, young, or aged. Is admirably adapted for delicate children and persons to whom quinine in any other form is objectionable, and is especially suited as a vehicle for the administration of Cod Liver Oil where the combined effect of Quinine and of the *Ol. Jecoris Aselli* is desirable. A wineglassful twice or thrice a day will be found both grateful and efficacious in all cases in which a cordial tonic is required—far superior to sherry and bitters or bitter beer.

[TESTIMONIAL FROM MISS EMILY FAITHFULL.]

"Victoria Press, 85, Praed Street, London, W., 20th August, 1871.

"Dear Sirs,—Having tested your excellent Quinine Wine, I am only too glad to testify to its efficacy in neuralgia, &c., as a certain cure and preventive, which is better than cure.—Yours truly, "EMILY FAITHFULL."

Sold by Grocers, Chemists, Patent Medicine Dealers and Confectioners, in Large Bottles, at 2s. each.

Goodall's Brunswick Black

For painting stoves, grates, iron, tin, &c. This invaluable composition is superior to any yet offered to the public, possessing great brilliancy, and thoroughly protecting the article it is applied to.

Sold in bottles at 6d. and 1s. each.

Goodall's Mushroom Ketchup

This splendid speciality is confidently recommended to all true lovers of the pure mushroom. It is prepared with the utmost care from the PURE JUICE, by a special steam process, secured at great cost by the proprietors, unrivalled for producing a ketchup uniform in strength, with a FULL AND RICH FLAVOR unpossessed by any other preparation of its kind in the market. One trial is sufficient to convince all of its great strength, perfect purity, and unsurpassed flavor.

Sold in bottles at 6d., 1s., and 2s. each, by Grocers, Oilmen, and Italian Warehousemen all over the kingdom.

Goodall's Baking Powder

THE BEST BAKING POWDER IN THE WORLD.

Warranted Pure, Free from Alum, and all other Injurious Ingredients.

AWARDED SEVEN PRIZE MEDALS.	MANUFACTURED FROM THE PUREST INGREDIENTS.
UNRIVALLED for EFFICIENCY and PURITY.	TESTIMONIALS INNUMERABLE.
RECOMMENDED by ALL WHO HAVE TRIED IT.	DISPENSES WITH BREWERS' YEAST.
DEFIES COMPARISON.	GIVE IT A TRIAL.

The cheapest because the best; indispensable to every household; and an inestimable boon to housewives. Makes delicious puddings without eggs, pastry without butter, and beautiful light bread without yeast. One trial will convince the most sceptical of its superiority over others.

[TESTIMONIAL.] "New North Road, London, N., May 4, 1875.

"Gentlemen;—Your Baking Powder is decidedly the best I ever used, and I shall recommend it to all my friends, being positive that it is the very best. "MARY WILSON, Matron."

Sold everywhere in 1d. Packets, 6d., 1s. 2s., and 5s. Tins, by Grocers, Oilmen, Chemists, &c.

Goodall's Custard Powder

For making delicious Custards, without eggs, in less time and at half the price. Delicious to plum pudding, delicious to jam tarts, delicious to stewed rice, delicious to all kinds of fruit, delicious to all kinds of puddings, delicious to all kinds of fruit pies, delicious to everything, delicious alone. Unequalled for the purposes intended. Will give the utmost satisfaction if the instructions given are implicitly followed. The Proprietors entertain the greatest confidence in the article, and can recommend it to housekeepers generally as a useful agent in the preparation of a good custard. GIVE IT A TRIAL.

Sold in boxes 6d. and 1s. each by Grocers, Chemists, Italian Warehousemen, &c.

[TESTIMONIAL.] "London, 8th February, 1879.

"Gentlemen,—Your Custard Powder is simply delightful, and cannot be approached by any powder I have hitherto used. "Yours respectfully, E. P.

"To Messrs. Goodall, Backhouse, & Co., White Horse Street, Leeds."

Goodall's Ginger Beer Powder

Makes three gallons of the best Ginger Beer in the world for threepence. The most valuable preparation for the production of a delicious and invigorating beverage. This Powder stands unrivalled, possessing valuable medicinal properties to a very large extent. It is not only cooling in its nature, but also an invaluable stomachic, thereby rendering it the most wholesome and perfect beverage ever discovered for both winter and summer. It is easily made, and acknowledged to be by far the cheapest and best Ginger Beer Powder ever offered to the public.

CAUTION.—To prevent disappointment be sure and ask for GOODALL'S GINGER BEER POWDER, as most of the so-called powders are made up of inferior articles, and contain little or no Ginger. Sold in Packets, 3d. and 6d. each, by all Grocers, Chemists, and Italian Warehousemen, &c.

Goodall's Egg Powder

The most valuable preparation in the world. Universally acknowledged to be the only real substitute for eggs yet discovered. This truly wonderful Powder has not gained its high reputation without meriting it to the fullest extent; its action on Cakes, Puddings, &c., &c., resembles that of the egg in every particular, enriching them in colour and flavour; also rendering them most wholesome and nutritious. Those who have not given it a trial should do so at once; they will find that one penny packet will go as far as four eggs, and one sixpenny tin as far as twenty-eight, thus making the cost one-fourth that of eggs. Sold everywhere, in 1d. packets; 6d. and 1s. tins. By Grocers, Oilmen, Chemists, Italian Warehousemen, Ship Store Dealers, &c.

MACKEY'S QUINQUININE.

Contains the pure alkaloids of finest Cinchona Barks, and takes the place of Quinine at less than half the price. It is found that the combined alkaloids of Bark, as they exist in their natural conditions, possess important advantages over the active principles in their separate state; this article, therefore, takes the place of Quinine, Quinidin, Cinchonine, &c., and is now used in our large Hospitals, and very extensively in private practice, acting with great energy, both as a tonic and anti-periodic, in 1 oz. bottles 5s. 6d.; also in 4 oz. bottles and 25 oz. tins. Dose—The same as Quinine.

In consequence of the high price of Quinine, we invite special attention to our Quinquinine, which, for the last ten years, has been largely used in Hospital and Private practice with the greatest satisfaction

MACKEY'S PHOSPHORATED FEVER SALINE.

A most valuable Preparation for use in Tropical climates, and in the treatment of Fever and feverish symptoms under any circumstances. It contains the soluble phosphates in an effervescing form, and is more grateful to the patient, and quenches thirst better than any other mixture of the phosphates.

Unlike most other Salines, it affords those elements to the system which tend to invigorate and strengthen the exhausted resources of Nature.

In Scarlet, Typhus, Yellow, or Jungle Fever, a teaspoonful every two hours in half a tumbler of water is one of the best remedies we possess. Sufferers from Gout and Rheumatic affections may take a teaspoonful twice a day in half a tumbler of water with great benefit. The ingredients of which this Saline is composed have received the highest Testimonials from the Medical profession in all parts of the world. In Bottles, 2s. 6d.; 4s. 6d.; and 10s. each.

MACKEY'S IMPROVED CHLORODYNE.

The great remedy for Diarrhœa, Cholera, Dysentery, Spasms, Palpitation, Neuralgia, Coughs, Consumption, Asthma, Bronchitis, &c., &c. Admitted to be the most valuable remedy ever discovered, and is approved by the Medical Profession, and supplied to Hospitals throughout the world. In bottles, with full directions, 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. each (less discount); also in Bulk for Dispensing, at 8s. per lb.

MACKEY'S MISTURA BISMUTHI COMP.

TONIC DIGESTIVE.—This valuable preparation is made in accordance with the Prescription of Dr. BROWNING, of London, and contains Bismuth in its most concentrated form. Highly recommended "in various forms of Indigestion, owing to its direct Sedative action on the Stomach, and marked, almost instant effect in checking Pyrosis, and the pain and vomiting occurring in the early stages of Pregnancy, or in course of Phthisis and malignant diseases. It is a valuable tonic in general functional atony, and in many cases of Constipation, Diarrhœa, and Dyspepsia. In *Infantile Diarrhœa* it is almost a specific. Its calmative action on the nervous system generally is worthy of notice. Each bottle has the Formula on the Label. Sold in ½lb., 1lb., 2lb., and 5lb. bottles at 10 per lb.

The above named preparations may be obtained from all Wholesale Druggists throughout the world, or direct from the makers, MACKEY, MACKEY & Co., Bouverie-street, London.

N.B.—Liberal discounts to the Trade.

THE

WEEKLY CEYLON OBSERVER.

THE best newspaper publication in the world for tropical planting intelligence and all matters affecting the statistics of production and the practical cultivation of coffee, cinchona, tea, cocoanuts, cinnamon, cacao, and other similar products. The proprietors and editors (Messrs. Ferguson) have had prolonged experience in Ceylon, as journalists, and in connection with planting. The paper is largely circulated in Ceylon, India, British Colonies, and the United Kingdom, also in Java and Brazil.

Subscription, including postage 18 rupees (£1 16*s.*) per annum in advance, and Advertisements at 9*d.* per line of 10 words.

Also published (annually) by Messrs. Ferguson, at their "Observer" Office, the "Ceylon Directory and Hand-book of Information," on subjects affecting tropical cultivation as well as all Ceylon matters—1,000 to 1,200 pages demy octavo, price, 8 rupees (16*s.*) per copy, including postage; Advertisements, Rs. 20 (£2) per page, or Rs. 12½ (£1 5*s.*) half page. Orders (with Bank Drafts) for all the above received at the "Observer" Office, Colombo, Ceylon; or through Messrs. Geo. Street & Co., 30, Cornhill, London, and Messrs. J. Haddon & Co., 3, Bouverie-street, Fleet-street, London.

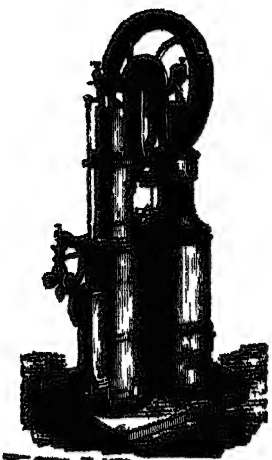
DOES NOT REQUIRE ANY SKILLED LABOR



Specially adapted for Pumping

EWELL, SURREY, June 13th, 1877.

MESSRS. HAYWARD, TYLER & Co.

Gentlemen,—The "Rider" Hot Air Engine you supplied some months since is working very satisfactorily. The cost of fuel is very trifling The only attention it has had has been that of the gardener's boy, 16 years of age. I consider it the most economical pumping power I have ever seen. I should be pleased to show it to any one you may send to see it.

Yours truly, WM. KILLICK.

"DAILY TELEGRAM OFFICE," WISBEACH, May 9th, 1877.

MESSRS HAYWARD, TYLER & Co., LONDON.

Gentlemen,—The One-Horse Hot Air Engine is now in daily work, printing off the "Daily Telegram" quite satisfactorily.

Yours truly, T. V. SUMFIELD

PATENT "UNIVERSAL" STEAM PUMPS,

FOR

IRRIGATION, MINING, OR PUMPING PURPOSES.

ECKINGTON, February 4th, 1877.

MESSRS. HAYWARD, TYLER & Co.

GENTLEMEN,

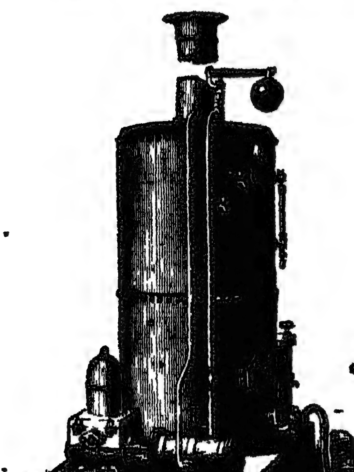
In reply to your inquiry, the 15 by 7 Long Stroke Pump, Messrs. Hayward, Tyler & Co. supplied us with is working remarkably well; 7 feet suction, and forcing the water 180 feet perpendicular, with 40lb of steam.

Before putting this engine in we had one H. P. Pumping Engine, 50 inch cylinder, 9 feet stroke, and firing six boilers, 36 feet by 4 feet, to drive it; now we only require two of the above boilers to do the same work with much less annoyance and attention.

I am, Gentlemen, yours truly,

JOHN MARPLES,

Engineer of J. and G. WELLS, Eckington Collieries.



HUDDERSFIELD, January 5, 1877

MESSRS HAYWARD, TYLER & Co

DEAR SIRS,

In reply to yours of 4th instant, we beg to say that the Steam Pump answers perfectly well as a Steam Fire Engine It has now been in use over 4 years, and we find it to answer quite as well now as it did at first.

Yours truly,

Pro. B. VICKERMAN & SONS

SOLE AGENTS FOR

Robey & Co.'s celebrated Portable and Fixed Engines and Machinery, Gwynne & Co.'s Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

Importers and Manufacturers of every description of Steam Engines and Machinery.

Robey & Co.'s Portable, Horizontal Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand Lift and Force Pumps, Gwynne's Centrifugal Pumps, Tangye's "Special" Steam Pump, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Stoney's Patent Soorkee Screwing Machines and Double Acting Helical Excavators, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selick's Boiler Tube Beaders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicators, Gifford's Injectors, Cooking Stoves, Fire Proof Safes.

The following are the principal advantages of the "Invincible" Pump.

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.

J. & H. GWYNNE'S "Invincible" Centrifugal Pump.

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent. lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied.

PRICES ON APPLICATION.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

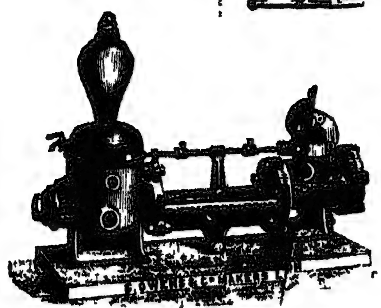
BLAKE'S PATENT DIRECT-ACTING STEAM-PUMP. MORE THAN 10,000 IN USE.

The following are some of the prominent advantages of the Blake Pump :—

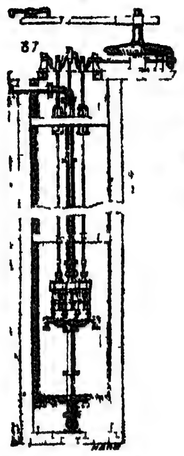
It will start at any point of stroke.
It has no dead point.
It works fast or slow with the same certainty of action.
It is economical. Has a lead on the Slide Valve.
It is compact and durable.

It is interchangeable in all its working parts.
It will deliver more water than any other Pump.
It is made of best materials in the most workmanlike manner.
Can be worked at 200 strokes per hour, or 20 strokes per minute.

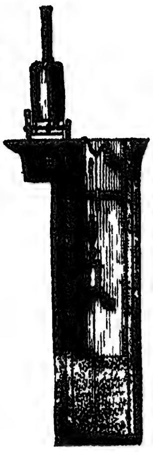
Hand Power Lever Det.



BLAKE'S PATENT
Direct-Acting Steam Pump and Boiler Feeder.



Deep-well Pumps, for Horse or Bullock power.



Vertical Combined Steam Engine, Boiler, and Deep-well Pumps.

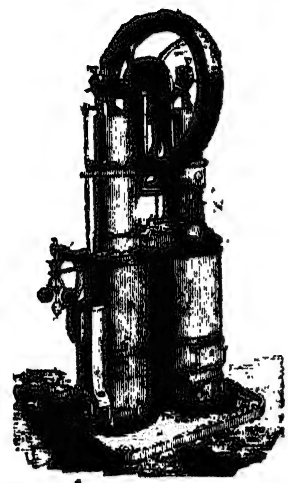
DOES NOT REQUIRE ANY SKILLED LABOR



Specially adapted for Pumping for

Ewell, Surrey, June 13th, 1877.
Messrs. Hayward, Tyler & Co.

Gentlemen,—The "Rider" Hot Air Engine you supplied some months since is working very satisfactorily. The cost of fuel is very trifling. The only attention it has had has been that of the gardener's boy, 16 years of age. I consider it the most economical pumping power I have ever seen. I should be pleased to show it to any one you may send to see it.

Yours truly, Wm. Killick.

"Daily Telegraph Office," Wisbeach,
May 9th, 1877.
Messrs. Hayward, Tyler & Co., London.

Gentlemen,—The One-Horse Hot Air Engine is now in daily work, printing off the "Daily Telegram" quite satisfactorily.

Yours truly, T. V. Sumfield.

WORKING PUNKAHS, HOUSEHOLD USE. OR IRRIGATION.

PATENT "UNIVERSAL" STEAM PUMPS,

FOR

IRRIGATION, MINING, OR PUMPING PURPOSES.

Bostwick, February 4th, 1877.
Messrs. Hayward, Tyler & Co

Gentlemen,

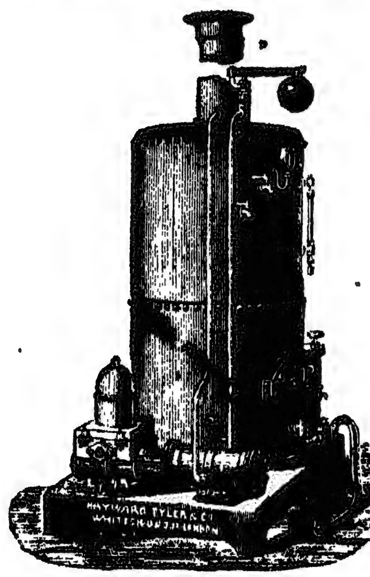
In reply to your inquiry, the 15 by 7 Long Stroke Pump, Messrs. Hayward, Tyler & Co. supplied us with is working remarkably well; 7 feet suction, and forcing the water 180 feet perpendicular, with 40lb. of steam.

Before putting this engine in we had one H. P. Pumping Engine, 50 inch cylinder, 9 feet stroke, and firing six boilers, 36 feet by 4 feet, to drive it; now we only require two of the above boilers to do the same work with much less annoyance and attention.

I am, Gentlemen, yours truly,

JOHN MARPLES,

Engineer of J. and G. Wells, Eckington Collieries.



Huddersfield, January 5, 1877.
Messrs. Hayward, Tyler & Co.

Dear Sirs,

In reply to yours of 4th instant, we beg to say that the Steam Pump answers perfectly well as a Steam Fire Engine. It has now been in use over 4 years, and we find it to answer quite as well now as it did at first.

Yours truly,

Pro. B. VICKERMAN & SONS,

TOM CROWE.

Robey & Co.'s celebrated Portable and Fixed Engines and Machinery, Gwynne & Co.'s Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

Importers and Manufacturers of every description of Steam Engines and Machinery.

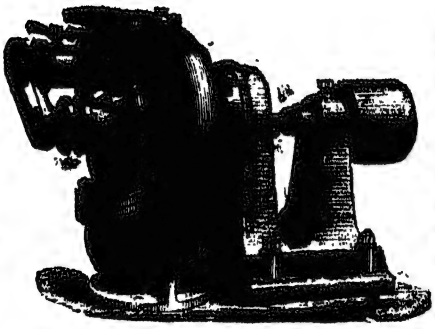
Robey & Co's Portable, Horizontal Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand Lift and Force Pumps, Gwynne's Centrifugal Pumps, Tangye's "Special" Steam Pump, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Stoney's Patent Soorkee Screwing Machines and Double Acting Helical Excavators, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Beaders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicators, Gifford's Injectors, Cooking Stoves, Fire Proof Safes.

The following are the principal advantages of the "Invincible" Pump.

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.



J. & H. GWYNNE'S "Invincible" Centrifugal Pump.

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent. lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied.

PRICES ON APPLICATION.
